Testing soil for available phosphoric acid by the Winogradsky method. E. M. NORRIS. *Fertilizer Green Book* **12**, No. 2, 30–1(1931).—Directions are given for carrying out the *Azotobacter* test for phosphate deficiencies in soils. K. D. JACOB

Phosphoric acid and plant growth. M. E. MORTON. Calif. Dept. Agr., *Monthly Bull.* **19**, 766–8(1930).—A general discussion. Most Calif. soils are deficient in P. C. R. FELLERS

Phosphorus-fixing compound in the soil. A. H. MEYER. *Science* **71**, 461(1930).—An Fe compd. existing as concretions in southern soils and responsible for the fixation of P has been discovered. The P is present as a basic ferrous phosphate of very low soly. B. C. A.

Influence of phosphoric acid on the cropping power of seed potatoes. DENSCH. *Superphosphat* **6**, 120–3(1930).—Phosphate deficiency in soil not only reduces the crop yield of potatoes but lowers the seed value of the tubers, which in the subsequent season produce smaller crops of lower starch content. Moreover, the smaller crops in the 2nd season are not improved by phosphate fertilizing. B. C. A

Critical consideration of fertilizer practice and crop yields in German agriculture. ALLEMEYER. *Superphosphat* **6**, 115–20(1930). B. C. A.

Chemistry and the fertilization of Italian soil. N. PARRAVANO. *Industria chimica* **5**, 1339–46(1930).—A history of the development of the fertilizer industry in Italy. A. W. CONTIERI

Factors in the production of synthetic and natural nitrates. LEE VANDERLINDEN. *Fertilizer Green Book* **12**, No. 2, 15–6(1931). K. D. JACOB

Developments in the production and use of concentrated fertilizers. C. H. KUNSMAN. *Fertilizer Green Book* **12**, No. 2, 20–2(1931). K. D. JACOB

Modern methods in fertilizer manufacture. B. LESLIE EMSLIE. *Sci. Agr.* **11**, 305(1931).—A general discussion. C. R. FELLERS

New fertilizer mixer calculator. E. L. RAYNAULD. *Sci. Agr.* **11**, 159–61(1930).—A device is described. It is simple, inexpensive and fairly accurate. C. R. FELLERS

Development of knowledge of rational application of commercial fertilizers and new knowledge in this field. O. ENGELS. *Kunstdünger u. Leim* **27**, 331–6(1930).—An account of the chem. methods and vegetation tests employed for estg. the fertilizer needs of the soil. C. J. SCHOLLENBERGER

Possibilities of sulfur as a soil amendment. G. S. FRAPS. Tex. Agr. Expt. Sta., *Bull.* **414**, 3–56(1930).—Field and pot expts. were conducted over a 4-yr. period. Chem. analyses show that alfalfa, cabbage, cotton, onions and turnips take up much larger quantities of S than corn, rice, oats and wheat. Some Texas soils are low in S. S is brought down by rain and also is supplied by irrigation water and in most com. fertilizers. The amt. brought down by rain in Texas averages 4 to 12 lb. a year on each acre, varying with different sections. Pot expts. show that S alone gave very poor results, but when it was used to supplement a complete fertilizer in pots watered with distd. water which

contained no S, it increased the yield of crops (in some cases). Addns. of S did not increase the amts. of N or K taken up by crops in pot expts., although they increased the S taken up and slightly increased the P. There was a tendency for the S removed by crops to increase as the S content of the soil increased. Oxidation of S had practically no effect upon the active P or active K in the soils tested, but increased the permeability of some of the soils to water. S is not recommended as a fertilizer on soils in Texas, since a sufficient amt. of S is present in the soils, or is supplied by rain or irrigation water or by com. fertilizers. S or $CaSO_4$ may be recommended in special cases on soils which run together under irrigation, or which contain black alkali. It is possible that the use of concd. com. fertilizers contg. little or no S may cause a deficiency of S in soils in some sections of the country, especially for crops which require comparatively large amts. of S, such as alfalfa, cotton, cabbage and onions. C. R. FELLERS

The effect of the admixture of magnesium with lime applications. O. K. ZIKHMANKEDROV. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 186-9(1930).—CaO, $CaCO_3$ (c. p.) and two kinds of limestone, one contg. 47% CaO and 23.3% MgO, the other 44.7% CaO and 25.2% MgO, were compared on podzol soils. The results showed that the Mg limestone was even slightly more effective than the pure $CaCO_3$. Another series of expts. was conducted with pure CaO, MgO, $CaCO_3$ and $MgCO_3$ alone or in combinations. Again the $MgCO_3$ showed no injurious effects, and in combination with $CaCO_3$ it stimulated the effectiveness of the latter. On some field plots the amt. of lime applied was almost equal to the hydrolytic acidity, and in every case the Mg-contg. limestones were very effective. It is concluded that limestones contg. CaO and MgO in the ratio of 2:1 or even 1:1 are not injurious; on the contrary it might be more beneficial than pure $CaCO_3$. J. S. JOFFE

The repressive effect of lime and magnesia upon soil and subsoil potash. W. H. MACINTIRE, W. M. SHAW AND J. B. YOUNG. *J. Agr. Sci.* **20**, 499-510(1930).—Data are presented from 5 lysimeter studies conducted over a 15-yr. period at the Univ. of Tenn. Agr. Expt. Sta. A 12-yr. expt. shows that economic addns. of CaO, MgO, limestone and dolomite, incorporated throughout the soil, depressed the soly. of native supplies of K. One-ton and 32-ton addns. of CaO and MgO produced the same repressive effect, even when supplemented by excessive quantities (added at once) of sulfates of Ca and Mg from $FeSO_4$ and progressive increments of the same salts from pyrite and S. A 15-yr. study with excessive quantities of 7 forms of Ca and Mg showed a decided decrease in the soly. of K in the surface soil and a marked decrease in the subsoil as a result of the influx of bicarbonate-impregnated percolates. A 4-yr. study with "light" and "heavy" forms of MgO and $MgCO_3$ and cryst. $MgCO_3.3H_2O$ showed the same consistent depression in K soly. Surface zone incorporations of $Ca(OH)_2$, limestone and dolomite produced neutral-salt-impregnated percolates that gave some indication of K liberation in an underlying unlimed zone of surface soil. Sub-surface zone incorporations produced the same repressive effect as the full depth incorporations. When K addns. were made by means of red clover hay along with $Ca(OH)_2$, limestone and dolomite, a decided decrease in the outgo of the K resulted. The results demonstrated that the liming of rock-derived soils under humid conditions will depress the hydrolytic disintegration of both the original K complex and that formed by fixation of added sol. K salts. It is further shown that the protective, or buffering, effect becomes more pronounced with increase in concn. of the bicarbonates of Ca and Mg. P. R. DAWSON

Plant-food value of mixed and fertilizing materials. BRUNO WAESER. *Metallbörse* **20**, 2021-2, 2077-8(1930).—A table shows ratios of N, P_2O_5 and K_2O contents of a number of common plants grown in Germany. The mean ratio for some 42 plants is $N:P_2O_5:K_2O = 1:0.47:1\ 42$. A similar table shows the same constituents in natural manures. The mean ratio here is 1:0.46:1.32. By combining these facts with the av. amts. of N, P_2O_5 and K_2O removed by various crops from the soil, a fair idea can be gained in regard to fertilizer requirements in Germany. The ratio of fertilizers actually used in Germany, in the case of 12 of the most important crops is $N:P_2O_5:K_2O$:lime = 1:0.449:1.256:0.66. Approx. the same ratio is found in artificial mixed fertilizers, such as KNO_3, $N:K_2O = 1:1.56$; Nitrophoska, $N:P_2O_5:K_2O = 1:0.825:1.413$; Am-Super, $N:P_2O_5 = 1:1.55$; Am-Sup-Ka, $N:P_2O_5:K_2O = 1:1.35:1.53$. A table shows the ratio of fertilizers applied to soil in some other European countries, also in Egypt and Japan. The av. ratio in these countries is $N:P_2O_5:K_2O = 1:2.11:0.81$. For the U. S., estimates are given for 3 ratio-types, $N:P_2O_5:K_2O = 1:3.33:1$; 1:5:1; 1:3:1. S. L. MADORSKY

Recent experiments on the preparation of organic manure. GILBERT J. FOWLER. *Agr. J. India* **25**, 363-85(1930).—Fermentation of org. matter in the prepn. of artificial

manure is facilitated by chopping the material into small pieces. The duration of fermentation is greatly diminished by the preliminary building up of a vigorously fermenting mass of material to serve as "activator," with which smaller quantities of less completely fermented materials are systematically mixed at suitable intervals. Insect larvae are practically eliminated by completing the fermentation anaerobically in pits. The necessary fermentation organisms may be obtained from either cow dung, cattle urine or night-soil, the latter always producing the most active fermentation. Fungi play an important part in the fermentation process, and materials contg. a high percentage of lignin cannot be rapidly fermented. There is some evidence that N fixation occurs during the process of fermentation. Data on the prepn. of artificial manure from *prickly pear, leaves, town refuse, mahua flowers, banana waste, leguminous plants* and *shrubs, sunn-hemp (Crotalaria juncea), weeds* and *green pea stalks* are tabulated.
K. D. JACOBS

Fermentation of compost and liquid manure. FRANZ SCHACHT. *Kunstdünger u. Leim* **27**, 306–8(1930).—Excessive fermentation induced by pumping liquid manure over solid stall manure can add nothing to the fertilizer value of the compost; the only advantage is in reduction of vol. by evapn., but this is accompanied by loss of N by volatilization as $(NH_4)_2CO_3$. Addn. of 18% superphosphate at the rate of 8–12 kg./cu. m. compost prevents loss by fixing NH_3 as nonvolatile phosphate. C. J. S.

Factors that influence nitrogen fixation in soils. THOMAS F. MANNS. Del. Agr. Expt. Sta., *Bull.* **167**, *Ann. Rept. Director* 44–52(1930).—Twenty years' expts. (with a rotation of wheat, mixed hay, corn and soy beans) are reported on N fixation in limed and unlimed plots receiving various fertilizer treatments. Conclusions: The use of lime, unless accompanied by K, resulted in less N gain in 20 years than shown by the unlimed plots, and lime was not a marked factor in N fixation. N losses from percolation in Del. probably reach 20% of that removed in the crops. K and P in combination were the most active factors in stimulating N fixation. K was the most active single element and the only mineral element that the crops removed in excess of that applied. C. R. FELLERS

The absorption of ammonium and nitrate nitrogen by various plants at different stages of growth. JAMES A. NAFTEL. *J. Am. Soc. Agron.* **23**, 142–58(1931).—Ammonium and nitrate N are absorbed by seedlings in appreciable amts. throughout all stages. $(NH_4)_2SO_4$ and $Ca(NO_3)_2 \cdot 4H_2O$ were used as sources of the N and similar results were obtained with all 3 plants (cotton, wheat and corn). The ammonium N is absorbed more rapidly in the early stages, after which the reverse is true. The best growth and earliest fruiting are obtained when there are both forms of N present. The easily sol. N of the seed and sap at the time of sprouting is present practically entirely in the ammonium form, and the N in this form is utilized much more rapidly than the nitrate N. The absorption of ammonium N increased as the acidity of the culture soln. decreased, while the absorption of the nitrate N was very slightly affected. The highest total N absorption usually occurred at p_H 6.0 and when both forms of N were present. A theoretical discussion of the observed phenomenon is included.
J. R. ADAMS

A comparison of various forms of nitrogen fertilizers. E. I. RATNER. *Udobrenie i Urozhai (Fertilizers and Crops)* **2**, 291–300(1930); cf. *C. A.* **24**, 1923.—The fertilizer values of $NaNO_3$, $(NH_4)_2SO_4$, $CO(NH_2)_2$, $CaCN_2$ and NH_4HCO_3 were tested in pot expts. on podsolized sandy loam, loam, degraded chernozem, deep chernozem, dark chestnut-brown, Turkestan loess and red soils (Roterde) with oats as the exptl. plant. None of the forms of N proved superior under all conditions. In the unsatd. soils cyanamide was superior to any form of N. On heavy loams $(NH_4)_2SO_4$ showed slightly higher effects. It is of interest to note that wherever $(NH_4)_2SO_4$ was not efficient the cyanamide was. It might be correlated with the different effects of these 2 forms of N on the reaction of the soil as shown in the tables presented. On some of the podsolized soils the tests were repeated, but to one series lime was added. The $(NH_4)_2SO_4$ was as good as the other forms of N on the limed soils. Cyanamide was superior to the others, even with lime, provided acid phosphate was used as the source of P. With pptd. phosphate the cyanamide was inferior. On freshly limed sandy loams (podsols) cyanamide was inferior, but on podsolized loams it was very efficient. Tests were also conducted with various moisture contents, but the results were of no significance. J. S. JOFFE

Effect of fertility on the carbohydrate-nitrogen relation in the soy bean. F. A. WELTON AND V. H. MORRIS. *Plant Physiology* **5**, 607–12(1930).—Soy beans grown in sand (3 parts of sand to 1 of Wooster silt loam) contained more dry matter and more total carbohydrates than did those grown in either soil (Wooster silt loam) or manure (3 parts of manure to 1 of Wooster silt loam). In general, the increase was due chiefly

to easily hydrolyzable carbohydrates, cellulose and lignin. The increase in carbohydrates in the plants grown in the sand was not accompanied by a simultaneous decrease in N as has been found with certain non-legumes (*C. A.* **14**, 1725–6). The high N content of these plants, however, was assocd. with the development of relatively large nos. of nodules on the roots of the plants. The stems of the plants grown in the sand were comparatively tough and rigid and not inclined to lodge. WALTER THOMAS

"Kalkammonsalpeter." O. NOLTE AND H. MÜNZBERG. *Mitt. deut. Landw. Ges.* **45**, 37(1930).—Comparison is made of the efficiency of "Kalkammonsalpeter," $(NH_4)_2SO_4$ and $NaNO_3$ in field trials. In dry seasons $NaNO_3$ was particularly effective, but in wet summers, when leaching losses were considerable, $(NH_4)_2SO_4$ proved the more profitable. "Kalkammonsalpeter" is preferable to either of the above for cereals and root crops. B. C. A.

The production of superphosphate from Khibinsk apatite. S. I. VOLFKOVICH, L. E. BERLIN AND L. B. GRINSHPAN. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 300–12 (1930); cf. *C. A.* **25**, 763.—Enriched apatite obtained from nepheline apatite rock by fine grinding and sieving or flotation is used on a semifactory scale for the production of acid phosphate. The quantity of H_2SO_4 to be used was based on the following equation: $2Ca_4F(PO_4)_3 + 7H_2SO_4 + 17H_2O = 3CaH_4(PO_4)_2.H_2O + 7CaSO_4.2H_2O + 2HF$. It was found that by using 88% of the rock milled to less than 0.1 mm. a 40% P_2O_5 raw product was converted to acid phosphate of a good phys. condition with 18% sol. P_2O_5. With 83% milled to less than 0.1 mm. the raw product contained 38.9% P_2O_5 and the final acid phosphate 16.2% P_2O_5. When the quantity of particles less than 0.1 mm. fell below 28–34% P_2O_5 the phys. condition of the final product was poor. It was found possible to mix the high grade nepheline apatite with the Vyatka raw phosphate low in P_2O_5 (24.5% P_2O_5), half and half, and still obtain a good product. J. S. JOFFE

Fertilization trials with potassium ammonium superphosphate on root crop. DENSCH. *Superphosphat* **5**, 53(1929).—The efficiency of the N of "Kali-ammon-superphosphat" is similar to that of the simpler nitrogenous materials, and the fertilizer proved suitable for use on acid soils and for acid-sensitive plants. B. C. A.

Changes in soil reaction produced by ammonium, potash and potash ammonium superphosphate. GERLACH. *Superphosphat* **5**, 282(1929); cf. *C. A.* **25**, 164.—The increasing acidity of many German soils is more definitely attributable to the normal processes of cropping and leaching than to the use of physiologically acid fertilizers. Systematic liming or marling is preferable to the withholding of valuable, if slightly acid, fertilizers. B. C. A.

Composition of ammoniated superphosphate. K. D. JACOB. *Phosphorus Digest*, pp. 5–6(Nov., 1930); *Fertilizer Green Book* **12**, No. 2, 10–1(1931).—The citrate-insol. P_2O_5 formed when superphosphate is treated with relatively large quantities of NH_3 is present principally as $Ca_3(PO_4)_2$. The phys. and chem. properties of $Ca_3(PO_4)_2$ are quite different from those of the P compds. present in phosphate rock, which is composed principally of Ca fluophosphate having essentially the same constitution as fluorapatite, $3Ca_3(PO_4)_2.CaF_2$. Recent expts. indicate that $Ca_3(PO_4)_2$ has approx. 75 to 80% of the fertilizer value of mono- and di-Ca phosphates during the first growing season, while phosphate rock usually has a much lower value. K. D. JACOB

The use of superphosphate on acid soils. H. KAPPEN. *Superphosphat* **6**, 66–8(1930); cf. *C. A.* **24**, 4576.—The long-continued use of superphosphate on heavy clay and light sandy acid soils does not have a significant effect upon the p_H values of such soils. When used continuously on limed soils superphosphate tends to further increase the p_H values of the soils. Basic slag and Rhenania phosphate have approx. the same value in reducing soil acidity, and it seems that with the quantities ordinarily used in actual practice neither of these materials reduces soil acidity to a significant extent. K. D. JACOB

Soil fertilization for sugar beets. JAMES TYSON AND M. M. MCCOOL. Mich. Agr. Expt. Sta., *Special Bull.* **205**, 3–31(1930).—Field expts. conducted on 3 of the most important sugar-beet soils in Mich. show the best fertilizer ratios to be 1:4:1 or 1:4:2. From 400 to 600 lb. of 4-16-4 or 4-16-8 mixts. gave most profitable returns. $NaNO_3$ when applied all at one time to the prepd. soil before sowing the seed was fully as effective as when the same amt. was applied in instalments. C. R. FELLERS

Fertilization and crop quality in root crops. KLEEBERGER. *Superphosphat* **5**, 74–6 (1929).—The effect of unbalanced fertilization on the quality of sugar beet and potatoes is examd. In this respect nitrogenous fertilizers are of first importance. The use of phosphate fertilizers in amts. based on Neubauer trials may be unsatisfactory, since this method of examn. allows of no consideration of quality. There is no foundation for the opinion that phosphate fertilizers are of minor importance for potatoes. B. C. A.

Action of ammonium sulfate and of sodium nitrate on the yield and starch content of potatoes. O. ENGELS. *Fortschritte Landw.* **5**, 97(1930).—$(NH_4)_2SO_4$ produced higher crop increases and starch content of potatoes than did $NaNO_3$. With each fertilizer there was an economic return. B. C. A.

Sources of nitrogen for potato fertilizers in Aroostook County. B. E. BROWN, F. V. OWEN AND E. R. TOBEY. Maine Agr. Expt. Sta., *Bull.* **354**, 38 pp.(1930).—During 16 years' exptl. work $(NH_4)_2SO_4$ produced a higher av. yield than $NaNO_3$, but comparable results depend primarily upon seasonal conditions. The most important effects of seasonal variations are (1) leaching of $NaNO_3$ during periods of heavy rainfall and (2) unavailability of $(NH_4)_2SO_4$ during periods of drought, especially on very acid soils. Although there is very little difference in the yields of potatoes following the use of inorg. sources of N as compared with inorg. N supplemented with org. N, it is not recommended that the practice of adding some org. N be discontinued, though the amt. may be reduced. From 5–6% of NH_3 (4–5% N) in the potato fertilizer mixt. gave the best results on Caribou loam soil type. N in potato fertilizers is an absolute necessity for high yields. Leunasalpeter, NH_4NO_3, NH_4Cl, $(NH_4)_3PO_4$, $Ca(NO_3)_2$ and especially urea compared favorably with $(NH_4)_2SO_4$ and $NaNO_3$ as single sources of N. Good results were also obtained with $CaCN_2$ when the amt. did not exceed 60 lb. per ton of mixed fertilizer. The degree of acidity and alky. of the soil and its ability to hold moisture are important factors in detg. the effectiveness of various N materials.
C. R. FELLERS

Effect of nitrogenous fertilizers on pastures. O. NOLTE, H. MÜNZBERG AND H. KOCH. *Mitt. deut. Landw. Ges.* **44**, 385(1929).—Results of meat and milk trials on fertilized pastures are recorded. B. C. A.

Effect of various fertilizer treatments on the yield and chemical nature of permanent pasture sod in the Piedmont section. J. P. LAMASTER. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention*, 148–58(1930).—Application of either a complete fertilizer or a N fertilizer alone greatly stimulated pasture growth for a period of 2 to 3 months following the application. A second and third application of a N fertilizer during the growing season greatly stimulated growth for a few weeks, the effect rapidly diminishing as the season advanced. Potash and phosphate fertilizers alone had very little effect in promoting growth of pasture, and little difference in the rate of growth was noted on the limed and unlimed plots. When superphosphate and lime were applied at the same time, reduced yields of green material and total P_2O_5 were obtained. On the basis of the whole season's growth, no significant differences in the percentages of N in the dry matter resulted from the various fertilizer treatments. The Ca content of the grass on all plots was very similar and followed the same trend through the season on all plots, the percentages being highest during the early season and lowest during the latter part of the season. The P content of the grass on all plots was also very similar. The percentages of P were high during the early growth period, low during midsummer and high again during the latter part of the growing period. K. D. J.

Fertilizer work with cabbage. L. M. WARE. Miss. Agr. Expt. Sta. *Circ.* **91**, 2–4 (1930).—Two yrs.' field expts. showed N was the only element which when added alone gave an increase in yield. The largest increase and net profit were obtained by the use of 532 lb. of $NaNO_3$, 1250 lb. of superphosphate and 160 lb. of KCl per acre.
C. R. FELLERS

Effects of certain soil conditions on the yield and quality of Burley tobacco. C. A. MOOERS. Tenn. Agr. Expt. Sta., *Circ.* **33**, 4 pp.(1930).—Tenn. tobacco fertilizers show an av. content of 2.5% N, 9% P_2O_5 and 4% K_2O Applications of from 500 to 1000 lb. per acre were more profitable and gave higher yields than light applications of from 100 to 450 lb. per acre. The use of manure also gave increased yields and profits.
C. R. FELLERS

Long-time fertilizer experiments (with peaches) in northeast Georgia. H. M. MCKAY. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention*, 318–25(1930).—Over a period of 10 years N-K fertilizers gave the greatest total wt. of fruit and the greatest no. of fruits per tree. Applications of P fertilizers alone gave poorer results than those obtained on the check plots. K fertilizers increased the yield of fruit, but to a less extent than N fertilizers. For the period of the expt. the increase in the circumference of the trees was 33 to 50% greater when N was used in the fertilizer, and the terminal growth was also greater. P hastened the maturity of the fruit while N retarded maturity to a marked extent. K. D. JACOB

Cotton fertilizer experiments, 1930. Sources of nitrogen, supplements and time and method of application. G. A. HALE. Ga. Agr. Expt. Sta., *Circ.* **91**, 4 pp.(1930).—Field expts. showed that the P in superphosphate or treble superphosphate (43%

P_2O_5) was somewhat more efficient than that in $(NH_4)_2HPO_4$ or $NH_4H_2PO_4$. A small amt. of cottonseed meal used with $NaNO_3$ caused the production of more cotton than the $NaNO_3$ alone. The ordinary complete fertilizers contg. N, P and K were improved by the addn. of small amts. of Mg and Ca. C. R. FELLERS

Chemistry and plant protection. A. CHWALA. *Oesterr. Chem.-Ztg.* **32**, No. 6, 45–8 (1930).—C. reviews the chem. insecticide and fungicide materials, their classification, application and properties. He criticizes the crude methods used in chem. labs. for detg. the toxic effectiveness of these materials and points out the important influence of phys. factors, such as soly., dispersion, size of particles, surface tension, resistance to weather, wetability, etc., on the toxicity. S. L. MADORSKY

Ability of dry fungicides to adhere to seeds. A. SIMSKII. *Udobrenie i Urozhai (Fertilizers and Crops)* **2**, 206–12(1930).—Into glass-stoppered jars of 600 cc. capacity 200 g. of grain is introduced and placed in cups of a revolving drum. The fungicide is added and the drum kept at a definite speed for different time periods. The seeds are taken out, passed over a 100-mesh sieve (100 openings per square cm.) and washed, and the amount of dusting material absorbed is detd. Wheat, oats and barley were used. Ca arsenate, Paris green, $CuCO_3$ and $CuSO_4$ dusts were washed with a weak soln. of HCl. It was found that $CuCO_3$ and anhyd. $CuSO_4$ adhere best to wheat and Ca arsenate to oats. The longer the seeds are mixed with the dusts the more is absorbed. J. S. JOFFE

Review of research on the control of wireworms. C. A. THOMAS. Penn. Agr. Expt. Sta., *Tech. Bull.* **259**, 2–52(1930).—One of the most effective baits consists of 6 lb. of $Ca(CN)_2$ per 1000 ft. of crop row. The rows should previously be liberally baited with wheat, oats or corn so as to attract the wireworms. The use of CS_2 emulsions on limited areas as in greenhouses or gardens is also fairly effective. There are 12 pp. of bibliography, many of the references being briefly reviewed in the text. C. R. FELLERS

Possibility of a new insecticide for use on citrus. L. B. RIPLEY AND G. A. HEPBURN. *Farming in S. Africa* **5**, 200, 241(1930); cf. *C. A.* **24**, 3596.—Na_2SiF_6 has for the Natal fruit fly a killing power 16 times that of Pb arsenate. Preliminary expts. with strengths needed to kill the fly caused no damage to citrus foliage, but it is known that considerably higher concns. are capable of severe foliage burning, and the limit of concn. for safe spraying has not yet been detd. K. D. JACOB

The influence of antiseptics on the supply of nutrients in the soil. G. A. CHIGAREV AND N. B. MYAKIVA. *Udobrenie i Urozhai (Fertilizers and Crops)* **2**, 312–7(1930).—By using CS_2 or polychlorides (a mixt. of chlorinated hydrocarbons of the benzene series, b. 130–200°, consisting primarily of the isomers of dichlorobenzene with some mono- and poly-chloro derivs.) as soil disinfectants it was found that the nitrates are inhibited to a great extent by the CS_2, but are stimulated by the polychlorides. NH_3 is stimulated by both disinfectants. Very little effect was noted on the P regime in the soil. J. S. JOFFE

Mango hoppers and mildew and their control. P. V. WAGLE. *Poona Agr. Coll. Mag.* **21**, 170–3(1929).—Mildew on mangoes is effectively controlled by dusting with S alone or with a mixt. of 6 parts of S and 1 part of $Ca(CN)_2$. S checks the activities of the mango hopper, but better control is obtained by dusting with the S-cyanide mixt. K. D. JACOB

The economics of pyrethrum. JOHN GLASSFORD. *J. Econ. Entomol.* **23**, 874–7 (1930).—Japan now produces $^6/_7$ of the world's pyrethrum flowers. Imports into the U. S. increased from 3 million lb. in 1923 to 9 million lb. in 1929. Av. consular invoice values decreased from 47¢ per lb. in 1923 to 18¢ per lb. in 1929. A pyrethrum spray contg. 0.04% of pyrethrum oleoresin and activated with soap costs 2.2¢ per gallon compared with 0.3¢ for a 1% lubricating oil spray, 1.2¢ for a Pb arsenate spray, 1.75¢ for a lime-sulfur spray and 1.84¢ for a nicotine spray contg. 0.04% alkaloid. C. H. RICHARDSON

Experiments with insecticides against cattle grubs (Hypoderma spp.). F. C. BISHOPP, E. W. LAAKE, R. W. WELLS AND H. S. PETERS. *J. Econ. Entomol.* **23**, 852–63(1930).—Single and repeated applications of various insecticides were made against cattle grubs in the backs of cattle. Special attention was given to insecticides in dust form. Ground derris root and dust carriers contg. derris ext. gave excellent results under varying conditions. Tobacco powder and dust contg. free nicotine and nicotine sulfate also gave a high degree of control. C. H. RICHARDSON

A comparison of the toxicities of *p*-dichlorobenzene and naphthalene to the confused flour beetle (Tribolium confusum Duv.) (Coleoptera). RUSSELL S. LEHMAN. *J. Econ. Entomol.*, **23**, 958–66(1930).—Adults of *T. confusum* were exposed to a series

of concns. of *p*-dichlorobenzene and naphthalene at 30° and 60–65% relative humidity. Air satd. with *p*-dichlorobenzene is strongly anesthetic to this insect. Based upon the time required to kill 50% of the insects, naphthalene was 10–14 times more toxic than *p*-dichlorobenzene at the same concn. C. H. RICHARDSON

Arsenical sometimes injures peach trees. W. C. DUTTON. Mich. Agr. Expt. Sta., *Quart. Bull.* **13**, 55–6(1930).—Pb arsenate used alone or in combination with other materials in the form of a spray or dust during the growing season may cause severe injury to leaves, wood and bark, often resulting in defoliation. Light applications and dil. concns. of sprays and dusts, as well as mixing of the Pb arsenate with lime, are recommended as precautionary measures. C. R. FELLERS

A new fungicide for the control of both peach and apple diseases. L. A. NIVEN. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention*, 308–10(1930).—With the exception of bitter rot, CaS sprays gave better control of peach and apple diseases than lime-S and Bordeaux sprays, and did not burn the fruit or foliage even under adverse weather conditions. K. D. JACOB

Influence of Bordeaux mixture on transpiration. W. H. MARTIN AND R. S. CLARK. New Jersey Agr. Expt. Sta., *Fiftieth Ann. Report*, 249–55(1929); *Rev. Applied Mycol.* **10**, 46.—An increase in transpiration rates in potatoes was noted after application of 5-5-50 Bordeaux mixture. Increased water loss occurred during the night following spraying of potatoes with Bordeaux mixture in soils previously adjusted to 15, 30 and 50% water content. The loss was particularly noticeable in the soils of high water content. Increased losses were observed in the 50 and 30 but not in the 15% moisture series during the day. O. E. SHEPPARD

Bunt of wheat in western Canada. W. F. HANNA AND W. POPP. *Sci. Agr.* **11**, 201–7(1930).—The CH_2O treatment of seed, even when badly infested with the *Tilletia* spores, gives satisfactory control of this disease. One lb. of com. CH_2O is used per bu. of seed. $CuSO_4$ and $CuCO_3$ are effective only when the seed is but slightly contaminated with spores. C. R. FELLERS

Sulfur dusting for the prevention of a bacterial disease of wheat called black chaff. F. J. GREANEY. *Sci. Agr.* **11**, 274–80(1931); cf. *C. A.* **24**, 5925.—The black chaff disease caused by *B. translucens* was largely prevented or controlled by frequent applications of S dust. The quality of the grain was also improved. C. R. FELLERS

The influence of sulfur dusting on rubber production. C. C. AMENT. *De Bergcultures* **4**, 823–5(1930); *Rev. Applied Mycol.* **10**, 55.—Dusting with S against mildew (*Oidium heveae*) on 2 out of 4 Hevea rubber estates in the Malang district of Java resulted in an increased yield of 22 and 14% over periods of 11 and 12 months, resp. The less productive parts of the estates were selected as controls in the expts.; so the results should be accepted with reservations. ODEN E. SHEPPARD

Sulfuring citrus trees. W. A. ROLFE. *J. Dept. Agr. Victoria* **28**, 732–3(1930).—Dusting citrus trees with powd. S at the rate of approx. 2 lb. per tree did not consistently increase the yield of fruit. K. D. JACOB

Defoliation of gooseberries by sulfur-containing sprays. HUBERT MARTIN. *J. South-Eastern Agr. Coll., Wye, Kent*, No. 27, 182–5(1930).—The Leveller variety of gooseberry is susceptible to defoliation when sprayed with either 1 in 60 lime-S, 3% dry-mix S-lime, or 0.4% colloidal S contg. 0.5% of soft soap. Addn. of $Al_2(SO_4)_3$ to the lime-S did not diminish the amt. of leaf fall. The expts. indicated that defoliation is caused by the action of elemental S and is not due to the presence of sol. sulfides. K. D. JACOB

Nicotine in paint for wooly aphis control. LEROY CHILDS. *J. Econ. Entomol.* **23**, 883(1930).—The woolly aphis attacks the callus tissue of pruning wounds, predisposing it to perennial canker infection. It was found that nicotine sulfate added to tanglefoot and tree paint which are applied to the wounds acted as a repellent to the aphids and as a contact poison to the young aphids when they attempted to establish themselves on the callus tissue. C. H. RICHARDSON

Neonicotine and certain other derivatives of the bipyridyls as insecticides. C. R. SMITH, C. H. RICHARDSON AND H. H. SHEPHARD. *J. Econ. Entomol.* **23**, 863–7(1930).—Twenty-five bipyridyl derivs. and related compds. not previously reported have been prepd. and examd. as contact insecticides. These include a no. of isomeric bipyridyls, bipiperidyls and pyridyl piperidines. Neonicotine (β-pyridyl-α-piperidine) was the most toxic of these compds., comparing closely with nicotine, to which it is chemically similar. α-Pyridyl-β-piperidine stands next in toxicity to neonicotine of the compds. investigated. In general, the compds. with the α,β and β,α groupings lead in toxicity over compds. with rings located in other positions. C. H. RICHARDSON

Results of airplane dusting in the control of cotton boll worm (Heliothis obsoleta

Fab.). FRANKLIN SHERMAN. *J. Econ. Entomol.* **23**, 810–3(1930).—**Large-scale airplane dusting operations with Ca arsenate in Texas showed that the cotton boll weevil might be controlled by the use of 5–6 lbs. Ca arsenate per acre. Cotton boll worms, however, were not controlled by this treatment, but increased in the dusted area during the season. Cotton boll worm damage was greater in treated than in untreated areas.** C. H. R.

Laboratory tests of miscellaneous chemicals against the codling moth. L. C. MCALLISTER AND E. R. VAN LEEUWEN. *J. Econ. Entomol.* **23**, 907–22(1930).—This is a study of the toxicity of a large no. of compds. to the newly hatched larvae of the codling moth (*Carpocapsa pomoneila*). Although no compd. superior in practice to Pb arsenate was found, about 50 were sufficiently toxic to be selected for further trial. Among these acetoacetanilide, diazoaminobenzene, dibromonaphthalene, 2,4-dinitrophenol, 3,5-dinitro-*o*-cresol, nitronaphthylamine, veratrine and nicotine were highly toxic to the larvae. C. H. RICHARDSON

Further results with trap baits for capturing the codling moth. M. A. YOTHERS. *J. Econ. Entomol.* **23**, 923–9(1930); cf. *C. A.* **24**, 4351.—Tests with trap baits to capture adults of *Carpocapsa pomonella* were made in a heavily infested apple orchard. The most promising baits were: malt sirup, cane molasses, beet molasses, brown sugar and geraniol. Variations in temp. affected the no. of moths captured more than did variations in dilu. of the bait. Geraniol increased the attractiveness of brown sugar and beet molasses baits. The capture of moths per trap increased with the no. of trees available from which to attract them, but not in direct ratio. C. H. RICHARDSON

Control of weeds by sodium and calcium chlorates. J. W. DEEM. *New Zealand J. Agr.* **41**, 1–3(1930).—$NaClO_3$ seems to give better control of weeds than $Ca(ClO_3)_2$, and it is cheaper and easier to handle. $Ca(ClO_3)_2$ readily absorbs moisture from the atm., but its fire risk is less than that of $NaClO_3$ Most soft weeds are killed by one application of either of these materials, while the harder weeds such as California thistle, blackberry, etc., are greatly weakened. K. D. JACOB

Eradicating perennial weeds with chlorates. A. C. ARNY, R. O. BRIDGFORD AND R. S. DUNHAM. Univ. Minn., Agr. Expt. Div., *Circ.* **32**, 4 pp.(1930); cf. *C. A.* **24**, 2538. C. R. FELLERS

Rotenone as a contact insecticide. W. M. DAVIDSON. *J. Econ. Entomol.* **23**, 868–74(1930).—Rotenone, the most toxic ingredient in *Derris* and some other plants, was tested in aq. suspension and in dust form (mixed with diatomaceous earth) against a no. of species of insects. The aq. suspensions were highly toxic to aphids, thrips, white fly larvae, leaf-hoppers, larvae of beetles, tent caterpillars, etc. Adult beetles, squash bugs, red spiders and mealy bugs were more resistant. The dusts were effective against chicken lice, roaches and cabbage worms, but the results obtained against soft-bodied sucking insects were not so good. C. H. RICHARDSON

The relative value as contact insecticides of some constituents of Derris. W. M. DAVIDSON. *J. Econ. Entomol.* **23**, 877–9(1930).—Aq. suspensions of the 4 principal toxic constituents of *Derris* root, *i. e.*, rotenone, deguelin, tephrosin and toxicarol, were tested as contact insecticides against aphids, thrips, white fly larvae and red spider mites. Their relative toxic values to *Aphis rumicis* stand with rotenone first in the approx. ratio of 400:40:10:1. Rotenone and deguelin are more toxic than nicotine to *A. rumicis*. This study indicates that the toxicity of *Derris* prepns. is due very largely to their rotenone content. C. H. RICHARDSON

Petroleum insecticides. C. W. WOODWORTH. *J. Econ. Entomol.* **23**, 848–51 (1930).—Kerosene emulsion has now been largely replaced by emulsions of the heavier petroleum oils. Heavy oils are selective in toxicity, systemic in their poisonous effects and are absorbed through the tracheae. Among the more than 100 com. brands of heavy oils now on the market, control labs. generally distinguish the following types: (1) *miscible oils* made with a cresol soap; (2) *soap emulsions* made with ordinary soaps; (3) the *nonsoap emulsions* commonly emulsified with alk. caseinate. Three types of oil are distinguished: (1) *the kerosenes*, about 40° Bé., constituting about 2% of the trade; (2) *summer oils*, about 30° Bé.; (3) *crude* and *winter oils*, about 20° Bé. The crude oils consist of a mixt. of oils varying widely in sp. gr. The winter oils are distillates from which the lighter and heavier fractions have been removed; some of them approach the summer oils in sp. gr. and refinement. Manufacturers often classify summer oils as heavy, medium and light, terms which are misnomers, as oils called heavy and light may have precisely the same sp. gr. The terms *thick* and *thin* are proposed for heavy and light. The following specifications for oils are given (the values denote, resp., sp. gr. in degrees Bé., Saybolt viscosity, percentage unsulfonatable residue, percentage distd. at 350° and 325°F. and, except in the first case, the percentage evapd. after 2 and 24 hrs.): ***winter oil***, **22° 110 sec., 68, 40, 15%; *thick oil*, 29° 110 sec., 97, 30, 10, 20,**

55%; *medium oil*, 30° 80 sec., 95, 50, 20, 30, 65%; *thin oil*, 30° 60 sec., 93, 75, 25, 40, 85%. It is conceivable that these phys. characteristics have no real significance in detg. the oils' efficiency as insecticides. The asphalt-base oils of California, which vary considerably in phys. characteristics, exhibit remarkable insecticidal efficiency. A tentative classification of the effect of oils on plants is outlined. Two new terms are proposed: *biolyte*, a general term for insecticides, fungicides, etc., and *biolysis*, the killing of pests. *Biolytology* is the science of economic poisons. C. H. RICHARDSON

Some physical properties of certain dormant oil emulsion-sulfur combinations. M. D. FARRAR AND M. A. SMITH. *J. Econ. Entomol.* **23**, 979-85(1930).—A petroleum oil emulsion for use in a dormant tree spray is described. This emulsion mixes readily with flotation S to give an effective combination spray for San José scale (*Aspidiotus perniciosus*) and peach leaf curl. The emulsion contains a vegetable gum emulsifier. When the emulsion and the S are mixed directly, the phys. properties are superior to the mixt. in which excessive water is added at time of mixing. Oils emulsified with a gum in combination with S were superior physically to those emulsions with K fish oil soap, K caseinate and petroleum soaps. Size of the S particles is a minor factor in these mixts. Flotation S contains small quantities of electrolytes which exert an important influence upon the oil emulsion mixt. The most desirable phys. properties of the mixt. were obtained when 4-6 lb. of flotation S was mixed with $1^1/_2$ gals. of the oil-gum emulsion and diluted in 50 gals. of water. C. H. RICHARDSON

A note on the relation between insecticidal action and the physical properties of soap solutions. P. A. VAN DER MEULEN. *J. Econ. Entomol.* **23**, 1011-2(1930).—This study is an effort to correlate certain phys. properties of soaps with their toxicity to insects. The adult Japanese beetle (*Popillia japonica*) was used as the test insect. As wetting and penetration are greatly influenced by the surface tension of the soln., this property was detd. with a Du Nouy surface-tension app. Surface tension was found to be very low and in all cases no definite relation existed between the surface tension of the soln. and its toxicity. The extent of penetration of a soap soln into the spiracles and tracheae of the beetle was not correlated with its toxicity. There was also no correlation between the viscosity of a soln. and its toxicity. When the soaps were allowed to evap. in the air on a glass surface, the surface became covered in most cases with a film of soap which differed greatly in strength with the different soaps. With the K soap made from palm oil, which was of relatively high toxicity, a very tough film remained upon the glass. The results show a relation between the toxicity to the insect and the tenacity of a film left after evapn. Soaps which form the toughest and most adherent films are most highly toxic, those which form less tenacious and weaker films are less toxic, while those which leave no film at all do not kill the insects. C. H. RICHARDSON

Densities of mixtures of air and various fumigants. R. C. ROARK AND O. A. NELSON. *J. Econ. Entomol.* **23**, 985-7(1930). The suitability of a compd. for use as a gaseous insecticide depends upon its toxicity, its vapor pressure and its vapor density. The vapor densities (in mass of 1000 cu. ft. of satd. mixt. of air and gas at 760 mm. Hg and 25°) and sp. gr. (air = 1) at 760 mm. and 25° of 29 compds., which have been used as fumigants for insects, are given in tabular form. Formulas for computing vapor density are also given. C. H. RICHARDSON

The calibration of flow meters for the measurement of insecticide gases. LYMAN C. CRAIG AND C. H. RICHARDSON. *J. Econ. Entomol.* **23**, 988-91(1930).—The calibration of resistance-tube flow meters for both large and small flows of air is described and the app. is illustrated. C. H. RICHARDSON

An additional statement concerning the tank-mixture method of using oil spray. RALPH H. SMITH. *J. Econ. Entomol.* **23**, 1009-11(1930).—Criticism of S.'s previous paper (*C. A.* **24**, 3594) has occasioned these remarks. The tank-mixt. method probably has an important place in the spraying of citrus trees in S. Calif.; whether it will be applicable to the spraying of deciduous fruit trees remains to be proved. Mech. mixts. of oil and water were used prior to 1910, but modern spray equipment and recent knowledge concerning the functioning of oil sprays indicate that a return to the original method is justified. The tank-mixt. method is based upon the use of an oil of given specification as to viscosity, distn. range and sulfonation. Insecticidal efficiency and injurious effect upon the plant depend entirely upon the amt. of oil deposited during spraying. The amt. deposited can be governed by placing the emulsifying material directly in the water in the spray tank, adding the oil and maintaining a uniform mixt. by means of agitators. The stability of the emulsion and size of oil globules, factors which heretofore have been the focus of oil-spray investigators, become relatively negligible. The dependability of the tank-mixt. hinges upon the proper agitation

and proper kind of emulsifier. The term "emulsifier" loses its significance when used in connection with the tank-mixt. method because an emulsion in the ordinary sense is not produced. The term "spreader" is perhaps more suitable. An investigation of spreaders for tank-mixt. sprays has shown that powd. blood albumin is one of the most promising substances for this purpose. C. H. RICHARDSON

The efficiency of the air-blast type of sprayer for applying insecticides. OLIVER I. SNAPP AND JAMES R. THOMSON. *J. Econ. Entomol.* 23, 884–5(1930).—The relative efficiency of com. air-blast sprayers and power sprayer outfits in applying lubricating oil emulsions and lime-sulfur soln. to deciduous fruit trees infested with San José scale (*Aspidiotus perniciosus*) was studied. No significant difference was found in the percent control with lubricating oil emulsion applied with the 2 types of sprayers. With lime-sulfur soln. the power sprayer gave greater efficiency than the air-blast type. C. H. RICHARDSON

Weathering of shell limestone and soil formation near Jena (HOPPE) **8.** Deodorizing reducing fertilizer from sewage, etc. (Brit. pat. 335,682) **14.** SeS_2 [fungicide or insecticide] (Fr. pat. 692,758) **18.**

Ergebnisse der Agrikulturchemie, Band II, 1930. Edited by F. HONCAMP. Berlin: Verlag Chemie, G. m. b. H. 196 pp. M. 13; bound, M. 14.

Mededeelingen van de Landbouwhoogeschool te Wageningen. Dl.34. Verhandeling. 7. I. Vergleichende mikroskopische, physikalische und chemische Untersuchungen von einem Kalkstein- und einem Löss-Bodenprofil aus den Niederlanden. II. Vergleichendes Studium von einem Kalksteinbodenprofil aus Java. By A. TE WECHSEL, L. MÖSER AND C. VAN AGGELEN. Edited by J. van Baren. Wageningen: H. Veenman & Zonen. 105 pp. Fl. 4.

Fertilizers. I. G. FARBENIND. A.-G. Brit. 335,175, June 15, 1929. Various granular fertilizers are prevented from caking by coating the granules with mineral oil or other oil insol. in water and non-volatile or but lightly volatile. Materials which may be thus treated include: urea, KCl and NH_4NO_3 or their mixts. with NH_4 phosphate, NH_4 sulfate nitrate, mixts. of NH_4NO_3 with $CaCO_3$ and other mixed fertilizers contg. NH_4, K or Na nitrates.

Fertilizers. LOUIS LONGCHAMBON. Fr. 693,306, July 10, 1929. The fertilizing value of phosphorous slags is increased and the grinding thereof is facilitated by dropping the molten slag into water.

Fertilizers. GIUSEPPE LOTRIONTE. Fr. 693,528, April 8, 1930. A fertilizing, stimulating and parasiticidal mixt. to be applied to parts of plants above the ground is composed of Fe 25, Cu 5, $Mn(MnO_2)$ 2, $K(K_2O)$ 1, $Mg(MgO)$ 3, $Ca(CaO)$ 28, $P(P_2O_5)$ 1, S 8 and inert substances and water 27%.

Fertilizers. SOC. D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIMIQUES (Georges Chaudron and Henri Herlemont, inventors) Fr. 693,319, July 12, 1929. Natural phosphates are made soluble by treatment with HCl or HNO_3 and sepd. from $CaCl_2$ and $Ca(NO_3)_2$ by conversion into insol. compds. such as phosphates of Cu, Sn or Fe. The insol. compds. are afterward converted into sol. phosphates for use as fertilizers. Cf. *C. A.* **24,** 3077.

Fertilizer. A. B. LAMB. Brit. 335,600, June 27, 1929. See Fr. 678,693 (*C. A.* **24,** 3599).

Fertilizer. EDWARD W. HARVEY (to The Barrett Co.). Can. 308,507, Feb. 10, 1931. A fertilizer is produced by treatment of $Ca(H_2PO_4)_2$ with atomized NH_4OH soln.

Fertilizers. J. VAN DER PLAES. Belg. 371,268, July 31, 1930. Raw manganiferous Ca phosphates are roasted in an oxidizing atm. Cf. *C. A.* **24,** 4888.

Basic phosphate slags. EISEN- UND STAHLWERK HOESCH A.-G. and FRIEDRICH HEINRICH. Fr. 692,510, Mar. 21, 1930. A compost of basic phosphates is made (1) by decanting Thomas flour or other basic phosphate slags in water, adding an acid or acid solns. and evapg., (2) by wet grinding in the presence of acids or acid salt solns., (3) by disaggregation with acids under high pressure or (4) by the action of finely pulverized acids or acid salt solns. on the slags. Fr. 692,511 describes the selective elimination of CaO from basic slags by treatment with acids or acid salt solns. so as to leave unmodified the constituent called silicocarnotite which is the soly. vehicle in citric acid.

Spray oils. WALLACE J. YATES (to Shell Development Co.). Can. 308,745, Feb. 17, 1931. A spraying liquid for insecticidal purposes consists of an emulsion in water of a petroleum spray oil, to which not over 1% of S has been added. Cf. *C. A.* 24, 5928.

Insecticide. STANDARD OIL DEVELOPMENT CO. Fr. 692,568, Mar. 22, 1930. An insecticide is composed of a naphtha or petroleum distillate having a b. p. above 205°, preferably between 205° and 280°, to which may be added exts. of pyrethrum, etc. Cf. *C. A.* 25, 1325.

Insecticide and fumigant containing ethylene oxide. RURIC C. ROARK and RICHARD T. COTTON (to the Government and People of the U. S. A.). U. S. 1,791,429, Feb. 3. A compn. suitable for fumigating foods, etc., comprises ethylene oxide as essential active agent.

Fungicide and bactericide. JOHN W. ROBERTS. U. S. 1,791,430, Feb. 3. A compn. suitable for combating fungi causing peach scab, etc., comprises a mixt. formed from $ZnSO_4$ 4 lbs., lime 3–4 lbs. and water 50 gals. Casein or alum may be added.

Fungicides for seeds. I. G. FARBENIND. A.-G. (Wilhelm Schepss, Wilhelm Bonrath and Carl Taube, inventors). Ger. 515,075, Sept. 23, 1927. Compds. in which Hg is linked to an aromatic hydrocarbon radical are used alone or with other fungicides, wetting agents or diluents. Among the compds. specified are PhHgOAc and $C_{10}H_7HgCl$. Cf. *C. A.* 24, 2539.

Fungicides for seeds. WILLI LENZ. Ger. 515,098, June 7, 1925. Water-insol. Cu compds. are mixed with alkali carbonates or bicarbonates and with hygroscopic compds. Adhesives, diluents, etc., may be included, but water-sol. fungicides should not be present. A suitable compn. contains $Cu(OH)_2$ 170, $CaCl_2$ 30, $NaHCO_3$ 50 and talc 50 parts.

Immunizing plants. Soc. D'ÉTUDES SCIENTIFIQUES. Fr. 693,723, July 18, 1929. Plants are immunized against the action of bacteria by the use of vaccines or artificial enzymes. Vegetable serums may be made by vaccinating plants and extg. and may be used in human and veterinary therapeutics.

Immunizing seed grain and preserving wood, glue, etc., from decay. I. G. FARBENIND. A.-G. Brit. 335,527, May 24, 1929. Fungicidal org. Hg compds. are used such as methoxyethylmercuric chloride or acetate, ethoxyethylmercuric chloride, methoxypropylmercuric acetate, phenoxyethylmercuric chloride, benzyloxyethylmercuric chloride, methoxyethylmercuric oxalate and methoxyethylmercuric hydroxide (details for the prepn. of some of which are given) and these compds. may be mixed with dry pulverulent diluents or with liquid vehicles. Cf. *C. A.* 24, 2828.

Mordants for seeds and for preserving and disinfecting grains, etc. I. G. FARBENIND. A.-G. Fr. 693,415, Apr. 5, 1930. Use is made of Hg compds. of the formula A. (A) XHgCRRCRROR′; (B) XHgCRRCRR–, in which X is a hydroxyl or any group forming with Hg a salt or a complex salt (acetate, lactate, oxalate, sulfate, chloride, thiocyanate, etc.). R is H, alkyl, aralkyl or aryl and may be the same or different in each position, and R′ is an alkyl, aryl or the group B.

Herbicides. I. G. FARBENIND. A.-G. Fr. 692,996, Mar. 28, 1930. Weeds, etc., are destroyed by solns. of salts such as chlorates to which are added a soln. of a wetting agent such as an aromatic sulfonic acid, the amt. of wetting agent added being small relative to the amt. of herbicide.

Weed killer. CHEM. FAB. LUDWIG MEYER. Ger. 515,414, Feb. 6, 1929. Addn. to 441,213 and 478,446 (*C. A.* 23, 4295). Solns. of heavy metal nitrates contg. free NO are used. Thus, 0.1–0.5% of NO in the form of HNO_2 or fuming HNO_3 may be added to a 1.5–7% soln. of $Cu(NO_3)_2$.

Destroying beet worms. CHEM. FAB. VON HEYDEN A.-G. (Walther Baunacke, inventor). Ger. 515,346 and 515,347, July 10, 1928. Formic acid is used, *e. g.*, by applying to the soil a mixt. of HCOONa 1 and $KHSO_4$ 2 parts (515,346). Picric acid may also be used and may be applied to the soil mixed with diluents, fertilizers, etc., or liberated in the soil by using mixts. of picrates with acid compds (515,347).

16—THE FERMENTATION INDUSTRIES

C. N. FREY

How much alcohol is produced by yeast? II. Checking of alcohol production. STAIGER AND GLAUBITZ. *Brennerei-Ztg.* 47, 127(1930); cf. *C. A.* 24, 4890.—Alc. was added to the original mash in various amts. (6, 8, 10 and 14%) and sugar was then added (75, 50, 25 and 0 g.). The alc. produced after 21 days was detd. The results were

10.6, 8.2, 6.0 and 2.2%, showing the alc.-producing ability of the yeast is checked when a certain concn. is attained. III. *Ibid* 146–7.—Various amts. (25, 30, 35 and 40 g.) of distillery, beer and wine yeast were used as seed. The results showed that the alc. production did not increase in spite of the increasing amts. of seed yeast, although the fermentation was completed sooner. S. Jozsa

Alcohol yields from corn and durra and from damaged raw material. Staiger. *Brennerei-Ztg.* **47**, 114–5(1930).—Ten corn samples, 2 durra samples and 12 miscellaneous grain samples were analyzed and the results of yield of alc. are given. S. J.

The balance in the fourth form of fermentation in the cell-free yeast fermentation. Maria Kobel and Max Scheuer. *Biochem. Z.* 229, 238–47(1930).—In expts. in which dild. yeast maceration juice acted upon hexosediphosphate pyruvic acid was isolated which was equiv. to 79% of the carbohydrate used and actually 100% of the sugar transformed. S. Morgulis

Further studies on the formation of methylglyoxal and pyruvic acid by yeast under the influence of various plasmolytic substances. Carl Neuberg and Maria Kobel. *Biochem. Z.* **229**, 255–62(1930); cf. *C. A.* **25**, 123.—The formation of $CH_3.CO.CHO$ from hexosediphosphate can be easily demonstrated in the presence of various plasmolytic agents (toluene, bromobenzene, various alcs., $CHCl_3$, CCl_4 and urethan) or of a high concn. of the diphosphate itself. The accumulation of $CH_3.CO.CO_2H$ can also be brought about by these means. S. Morgulis

Decomposition of non-phosphorated sugar by yeast with the formation of glycerol and pyruvic acid. Carl Neuberg and Maria Kobel. *Biochem. Z.* **229**, 446–54 (1930).—The fermentation of the Mg salt of fructose, diphosphate as substrate, yields 100% of the theoretical amt. of glycerol and pyruvic acid. Both these substances are recovered, though in smaller quantities, even when a 10% glucose soln. contg. 0.125–0.75% $Mg_3(PO_4)_2$ is fermented by fresh press yeast. The $Mg_3(PO_4)_2$ can be replaced by Na_2HPO_4. However, since MgO acts just as well, the presence of the phosphate ion is not essential, nor is the Mg ion indispensible because the Mg salt can be replaced by Na_2HPO_4. The glycerol and pyruvic acid appear in equiv. amts. under conditions where no cell multiplication takes place (yeast juice or suspension preserved with antiseptics), but the equivalence disappears when one works with living yeast cells. Cf. *C. A.* **24**, 1398, 3078. S. Morgulis

Formation and identification of acids produced by different strains of propionic acid bacteria. P. W. Wilson, E. B. Fred and W. H. Peterson. *Biochem. Z.* **229**, 271–80(1930).—Eleven strains of propionic acid bacteria were examd. from the standpoint of their ability to ferment glucose, lactose and maltose, from which volatile acids were produced. In pure cultures sugar was used up only partially but in the presence of *L. casei* all the sugar was used up and 25–75% converted to volatile acids. The most active strains were employed in the fermentation of meal from malted corn, molasses or hydrolyzed starch, only the latter 2 being quickly fermented. The activity of the different strains varied, of course, but those fermenting pure sugar most effectively did so also with the natural sources of sugar. Yeast water or the residue in the distn. of acetone-BuOH fermentation served well as the N sources. Acetic and propionic acids were isolated and identified as the volatile products, the latter constituting 65–70% of the total. S. Morgulis

Studies on slops. Staiger. *Brennerei-Ztg.* **47**, 142(1930).—The moisture, acidity and alc. content were detd. on 9 different samples of residual liquid from distn. of alc. liquors. The protein, fat, crude fiber, N-free ext. and ash were detd. on 3 rye slops. S. Jozsa

Slop and its significance in agriculture. K. G. Schulz. *Brennerei-Ztg.* **47**, 162 (1930). S. Jozsa

Removing wood taste from wine brandies. C. Luckow. *Brennerei-Ztg.* **47**, 138 (1930).—Two samples of wine distillate were stored in wooden barrels and had a strong oak-wood taste. By using 10 g. gelatin per 100 l. distillate, or 1% skim milk, the undesirable taste was practically removed. S. Jozsa

Formic acid, a constituent of the volatile acids of wine, and its determination. W. Seifert and Marie Ulbrich. Expt. Sta. Klosterneuburg, *Denkschrift*, 70th anniversary, 148–63(1930); cf. Kreps, *C. A.* **5**, 1305; Fincke, *C. A.* **5**, 1300, 3705; **6**, 1787; **7**, 2258.—The method of F. for detg. HCOOH is very exact, but laborious; the $KMnO_4$ method of Lieben (1893) was here adopted, and the results of the examn. of 24 samples of Austrian and Hungarian wines are tabulated. Conclusions: (1) The content of free HCOOH varies from 0.023 to 0.089 g. per l.; the quantity bound as ester is greater or smaller; no regularity is apparent. (2) The ratio of free HCOOH to volatile acids shows very wide limits: 3.4–21.6% in grape wines; 5.2–9.5% in raisin wines; and 7.1–

10.5% in fermented fruit juices. (3) The highest content of HCOOH is found in 1 of 2 Tokay wines examd.: 0.089 g. free, 0.214 g. total per l. K. records for Tokay wines 0.173–0.517 g. total HCOOH per l. These wines are usually left on the lees for about 1 year, then are stored in incompletely filled barrels in order that the characteristic "bread" taste may form. Yeast activity is thus renewed and volatile acids are formed. In the decompn. of leucine of yeast, HCOOH is split off (F. Ehrlich, 1905). (4) Two raisin wines prepd. by S. and U. contained only 0.108 and 0.091 g. per l. of total HCOOH, probably because 4 g. tartaric acid per l. had been added to exclude secondary fermentations. Khoudabachian (1883) found in a raisin wine 0.94 g. AcOH and 0.28 g. HCOOH per l., probably caused by the presence of bacteria. (5) The undild. juices of currants and raspberries fermented with pure yeast contained when examd. fresh only 0.052 and 0.062 g. total HCOOH, whereas K. had observed in stored raspberry wine 0.323–0.542 g. per l. The cause of this difference will be further studied. Fruit juices apparently keep best when they are fermented with pure yeast, withdrawn from the sediment early and filtered. S. Waldbott

Determination of glycerol in wines and fermented beverages. Lucien Semichon and Michel Flanzy. *Ann. fals.* **23**, 583-602(1930); cf. *C. A.* **24**, 2231.—S. and F. recommend the following technic, which is a modification of that of Ferré and Bourges (*C. A.* **22**, 4713): Place 20 cc. of wine in a 100-cc. volumetric flask, make up to 100 cc. with neutral 95% alc., add to 5 g. BaO and triturate in a mortar for 2–3 min., return to the volumetric flask, let stand 30 min. and filter (preferably through a Gooch crucible). Pass CO_2 for 2 min. through a 50-cc. aliquot in a 100-cc. Erlenmeyer flask, evap. to about 10 cc., add 20 cc. water, evap. to 15–20 cc., let cool, make up to 50 cc. and filter. Steam-distil 25 cc. (=5 cc. of original sample) under a partial vacuum of 30–40 cm. of Hg, absorbing the distillate in a mixt. of 10 cc. CrO_3 (63 g. per l.) and 20 cc. of 60° Bé. H_2SO_4. Immerse the tube contg. the sample to be distd. in a vaseline-oil bath heated to 115–120°, which also contains a coil for superheating the steam used for the distn.; place the absorbing soln. in a 500-cc. Durand washing flask immersed in a boiling-water bath. After distg. for 3 hrs., titrate the excess CrO_3 with $Fe(NH_4)_2(SO_4)_2$ soln. (149.13 g. per l.), using $K_3Fe(CN)_6$ as outside indicator; 69 mg. glycerol is completely oxidized by 350 mg. CrO_3. Details are given of the investigation of the method, and data are furnished justifying the various steps of the technic. A. Papineau-Couture

Experiments toward determination of sorbitol according to Werder and Zäch. Rudolf Haid and Franz Popberger. Expt. Sta. Klosterneuburg, *Denkschrift*, 70th anniversary, 90–3(1930); cf. Werder, Zäch and others, *C. A.* **23**, 928, 4296; **24**, 5105.—Heretofore, not much less than a 10% admixt. of fruit wine to grape wine could be detected by isolating dibenzalsorbitol (*A*). A 3% addn. contg. 7.5–39 mg. sorbitol per 100 cc. (cf. Fellenberg) should yield about 15–78 mg. of *A*, of which only 5–10 mg. is needed for the Tutin identification test. However, a 3% addn. yields only 3–5 mg. water-insol. *A*. To obtain a max. yield of *A*, the temp. must be kept at 0°, a min. concn. of 1:1 H_2SO_4 and a certain excess of BzH must be used; *e. g.*, 30 mg. sorbitol, 0.65 cc. H_2SO_4 (1:1) and 0.2 cc. BzH (6 drops) at 0° yielded 54 mg. of *A*. Slight deviations alter the yield considerably. S. Waldbott

Brewing as a branch of science. Arthur R. Ling. *Brewers J.* **66**, 302–6(1930).—The biochem. processes involved in the brewing of beer are outlined. P. J. F. W.

English barleys of 1929. H. M. Chubb. *J. Inst. Brewing* **36**, 221–4(1930).—In contradistinction to the heavy barley of the 1928 season, those of 1929 are light, the greater bulk reducing the malt house output by 5%. Germination on the floor was good and regular. Diastatic power and cold water exts. of the malts were below normal. Peter J. F. Weber

Foreign barleys of 1929. T. R. Sutcliffe. *J. Inst. Brewing* **36**, 225–6(1930).—California barley malted well and gave high to abnormally high exts., while Chile produced a barley of av. quality. The crops of other barley-growing countries were of inferior quality. Peter J. F. Weber

Some recent advances in the chemistry of enzymes. R. H. Hopkins. *J. Inst. Brewing* **36**, 189–94(1930).—See *C. A.* **24**, 2764 (the vol. no. given for *Chem. News* is an error for **140**). Peter J. F. Weber

Cleaning and disinfecting agents (in the brewery). P. Petit. *Brasserie & malterie* **20**, 337–42(1930).—A brief discussion of the proper method of cleaning and disinfecting piping and bottles. A. Papineau-Couture

Attenuation. J. de Clerck. *Bull. assoc. anciens eleves de Louvain*, March, **1930**; *Brewers J.* **66**, 293–4(1930).—The factors influencing attenuation of fermenting liquids are discussed. Peter J. F. Webber

The brewing value of hop tannin. A. A. D. Comrie. *J. Inst. Brewing* **36**, 307–11

(1930).—Research thus far indicates that boiling a malt wort renders part of the nitrogenous constituents insol. The tannin of the hops accelerates pptn. through the formation of tannin-nitrogen compds., which, however, only become quite insol. by conversion of the tannin into its deriv., phlobaphene. The tannin-nitrogen compds. sometimes pass into the beer and can produce haze of two kinds: reversible (when the soly. is reduced by chilling) or irreversible (when the tannin is converted into the insol. phlobaphene by heating, such as pasteurization). PETER J. F. WEBER

The solubility of maize proteins in mashing. II. R. H. HOPKINS. *J. Inst. Brewing* **36,** 297–304(1930); cf. *C. A.* **24,** 1929.—Lab. fermentations of malt and malt maize worts having similar ds. and contg. approx. 50 mg. of assimilable N per 100 cc. justified the conclusion that the N derived from maize is almost wholly left in the beer after a single fermentation. A second seeding of the fermented worts with yeast indicated that the maize N would be ultimately assimilable. PETER J. F. WEBER

Respiration and fermentation of top and bottom beer yeast. KURT TRAUTWEIN AND JOSEPH WASSERMANN. *Biochem. Z.* **229,** 128–53(1930).—The rate of respiration of top yeast is on the av. 77% higher than that of the bottom yeast. The top yeasts rise to the surface during fermentation where they can easily find O_2 and thus become acclimated to an aerobic existence. But here the increase in the respiration capacity is accompanied by a similar increase in the fermenting capacity so that the ratio between their rates remains const. Both types of yeast, however, use up 2–3% of the total sugar undergoing dissimilation in the respiration and 98–97% in the fermentation. If the energy value of both the respiratory and fermentative processes is calcd. the total metabolism of the top yeast is found to be 42% higher than that of the bottom yeast. In the top yeast 40% of the total metabolism is respiratory and 60% fermentative, while for the bottom yeast these values are 32 and 68%, resp. S. MORGULIS

Research work in the yeast field. L. H. LAMPITT. *J. Inst. Brewing* **36,** 250–60 (1930). -A review of results obtained, and of problems to be solved in the study of the life and activity of yeast. PETER J. F. WEBER

Alcohol losses in yeast manufacturing. F. WAGNER. *Brennerei-Ztg.* **47,** 162–3 (1930).—The losses on alc. due to aeration were studied on 3 different molasses mashes diluted 8, 16 and 20 times, resp. The amt. of air per cu. m. liquid was 25, 70 and 70 cu. m., resp. The alc. content of the air leaving the system was detd., and it was found that the losses of alc. increased with stronger aeration, and decreased with lower alc. content. S. JÓZSA

Losses of water-soluble phosphoric acid by the clarification of molasses under acid conditions and heat. O. HUMMER. *Brennerei-Ztg.* **47,** 142–3(1930).—The loss of water-sol. P_2O_5 increases rapidly with decreasing acidity. S. JÓZSA

Korean koji (a kind of the so-called Chinese yeast). HIROSUKE NAGANISHI. *Abstract from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 41–2.—Thirty-seven mold fungi, 9 yeasts and 4 bacteria were found in this prepn. The diastatic powers of the molds are detd. V. F. HARRINGTON

Involution cultures of yeast 1. A. T. HENLEY. *J. Inst. Brewing* **36,** 304–7(1930).—To obtain surface growths of yeast which shall be characteristic and help in the differentiation of species, specially prepd. wort-carrigeen moss (*Chondrus chispus*) in Erlenmeyer flasks was inoculated with a wild yeast (*S. pastorianus*) and a culture yeast (Dublin No. 1). The growths thus obtained were distinctly different from each other, since the colonies were able to grow freely along any individual lines they may have possessed and yet could not sink into the body of the media. Under these conditions a high percentage of mycelial cells was formed and gave rise to the term *involution culture*. The gel produced by the addn. of carrigeen moss to wort was fragile, only a little agitation breaking it down. Details of the method of prepn. are given. P. J. F. W.

The use of microörganisms in certain commercial processes (HUBERT) **23.** The preservation of sweet must (MEHLITZ) **12.**

VENTRE, J.: **Traité de vinification pratique et rationnelle. Tome I. Le raisin et les vinifications.** Paris: Dunod. 490 pp. F. 50.

Fermentation products. ZELLSTOFFFABRIK WALDHOF and MAX GADE. Fr. 693,553, April 8, 1930. In the distn. of alc. from a fermented sulfite wort the first running contg. aldehyde is directed to a fresh wort about to be fermented.

Dehydrating alcohol. WM. H. ENGELS (to Merck & Co.). U. S. 1,790,907, Feb. 3. A hydrous alc. is mixed with comminuted CaO in relatively small excess as proportioned

to the amt. of water to be removed, the mixt. is heated and refluxed and the film of hydrated lime is continually removed as it forms upon the surface of the particles of oxide by the action of mech. agitation; this operation is continued to completion of the dehydration and the treated alc. is distd. off under continued agitation. A "com. pure" hydrated lime is obtained as a by-product.

Butanol and acetone. AUGUSTE FERNBACH. Fr. 693,744, July 23, 1929. In the production of butanol and acetone by the fermentation of materials contg. saccharose, inversion of the saccharose is obtained by the action of sucrase or invertase, yeast being used as the source of sucrase. The medium is kept at a p_H value of 4.3–4.5.

Lactic and acetic acids. WISCONSIN ALUMNI RESEARCH FOUNDATION. Brit. 335,596, June 20, 1929. Lactic and acetic acids are produced by fermentation of pentoses and hexoses (such as those from wood, sawdust, straw, corncobs or the like) by the action of a described microörganism obtained from fermenting plant material such as silage or sauerkraut. Various details of procedure are described.

Glycerol. VEREINIGTE CHEM. WERKE A.-G. Ger. 514,395, June 22, 1926. In the manuf. of glycerol by fermenting sugar in alk. soln. in the presence of Na_2SO_3 the volatile fermentation products are distd. off, and the residual mash contg. glycerol is fermented again after addn. of more sugar, these steps being repeated as required. The yeast should preferably be filtered off before removing the volatile products. Examples are given.

Yeast. KRAUSZ MOSKOVITS VEREINIGTE INDUSTRIE-ANLAGEN A.-G. Fr. 692,546, Mar. 21, 1930. Yeast of high enzymic activity is prepd. from yeast multiplied according to any known process, which is further developed in 2 working stages in such a manner that in the one stage, by assimilation, nitrogenous substances complete the plasma of the yeast cells with simultaneous inhibition of multiplication and in the other stage, by setting up a strong fermentation; the enzymes of the cells are caused to develop, the 2 stages being effected in either sequence.

Preparation of air yeast and other microbiological processes employing the passage of gas through the culture medium. HENDRIK C. JANSEN. Dutch 22,653, Sept. 15, 1930. Substances which are to be added to the nutrient medium are mixed in with the gas passed through the medium. Liquids or solids are sprayed into the gas.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

The chemical examination of Sida cordifolia, Linn. SUDHAMOY GHOSH AND ASHUTOSH DUTT. *J. Indian Chem. Soc.* **7**, 825–9(1930).—Berela (*S. cordifolia.* L.), regarded as a most valuable drug in the Ayurvedic system of medicine, and used as an aphrodisiac by the Mahomedan hakims, has not previously been examd. systematically. Assays of the entire plant by the U. S. P. method for belladonna showed the presence of 0.085% total alkaloids, the seeds contg. 4 times more alkaloid than the leaves, stems or roots. Extn. with petr. ether, Et_2O, abs. alc. and H_2O showed the presence of fatty oil, phytosterols, resins, resin acids, mucins, KNO_3 and alkaloids, but no tannin or glucoside. The alc. ext. contained the whole of the alkaloid content. From 100 kg. of the air-dried drug a crude alkaloid residue was extd., $^1/_5$ of which was $CHCl_3$-sol. The remainder gave a *cryst. HCl salt*, m. 215.5°, α_D^{22} —35.0, *chloroplatinate* m. 190.5°, mol. wt. 165, mixed m. p. with ephedrine-HCl from *Ephedra vulgaris* 215.5° (ephedrine-HCl, m. 215–6°, α_D —32.5; mol. wt. 167). The $CHCl_3$-sol. fraction was non-cryst. but appeared to contain alkaloids related to ephedrine. Ppts. with 11 alkaloidal reagents and the violet color of the biuret reaction confirmed the identity of the alkaloid from Berela with ephedrine. Pharmacologically, the alkaloid hydrochloride causes marked and persistent rise of blood pressure in the absence of ergotoxine, dilation of the bronchioles and inhibition of intestinal movements; these effects resemble those of sympathomimetic bases such as adrenaline or ephedrine. C. R. ADDINALL

The distillation of essential oils. V. I. VARENTZEV. *J. Chem. Ind.* (Moscow) **6**, 1602–4(1929).—The extn. of essential oils from their seeds by steam distn. can be expressed by the formula of an infinite decreasing geometrical progression: $S = a/(1 - r)$ and $l = ar^{n-1}$. Thus, by experimentally establishing a (the amt. of oil extd. in the first hr.) and r (the ratio of the amt. of oil extd. between 2 consecutive hrs.) the duration of the distn. of the oil content of the seeds can be easily calcd. The validity of this "distn. law" is shown by numerous examples taken at random from the literature.

E. BIELOUSS

The seeds and oil of Sinapis dissecta Lag. N. BELYAEV. *Masloboino Zhirovoe Delo* **1929**, No. 6, 25–6.—This plant, found abundantly in the Saratov region, is a variety of the common *Sinapis alba* L. The seeds contain moisture 8.80, oil 28.95, fiber 15.06, ash 4.48, total N 3.83, crude protein 23.90 and essential oil 0.09%. The oil has d. 0.9150, solidification point 15, n_D^{20} 71.9, sapon. no. 172.4, I no. (Hübl) 100.52, acid no. 1.64. The fatty acids have I no. 99.38, m. 21°, solidify 18°. The oil is thus similar to the oil of *Sinapis alba*. E. BIELOUSS

Investigation of the essential oil from different kinds of fennel cultivated in the Krasnodar district. N. SOBYANIN AND S. SAAKOV. *Masloboino Zhirovoe Delo* **1929**, No. 6, 34–6.—Fennel oils of different origins vary in yield from 1.21 to 5.3%, in optical rotation from +5 to +20.3, in *n* from 1.528 to 1.5405, in solidification point from 3° to 12°. E. BIELOUSS

Comparative value of metaphen in alcohol-acetone-aqueous solutions in the pre-operative disinfection of the skin. WINFIELD W. SCOTT AND KONRAD E. BIRKHANG. *Ann. Surgery* **93**, 587–97(1931).—A 0.5% alc.-acetone-aq. soln. of 4-nitro-5-hydroxy-mercuri-*o*-cresol is a satisfactory pre-operative skin disinfectant. RACHEL BROWN

Note on the biological assay of tincture digitalis. G. A. GRANT AND S. G. ALEXANDER. *Proc. Trans. Nova Scotian Inst. Sci.* **17**, 244–7(1930).—The strength of several samples of Tr. digitalis was detd. by the biol. assay outlined at the Geneva Conference. The results obtained indicate that for the tinctures examd. the max. deviation from the U. S. P. X standard is much less than that previously found and that the strength of the International powder is considerably above that of the present U. S. P. X standard. RACHEL BROWN

The germicidal action of ethereal oils. SIEGFRIED L. MALOWAN. *Z. Hyg. Infektionskrankh.* **112**, 93–4(1931).—The chem. compn. as well as the H_2O soly. affect the germicidal action of ethereal oils. Oils contg. aldehyde are most active and have a high soly.; oils contg. esters are less active than alcs. RACHEL BROWN

Bulgarian Otto of Rose. ERNEST S. GUENTHER AND ROBERT GARNIER. *Am. Perfumer* **25**, 417–20, 479–82, 547–50, 621–4(1930).—An exhaustive review is given of the natural rose oil industry as practiced in Bulgaria, with illustrations. W. O. E.

Leaf oil from Dacrydium franklini Hooker. A. R. PENFOLD AND J. L. SIMONSEN. *J. Proc. Roy. Soc. N. S. Wales* **63**, 95–101(1930).—A renewed study of the hydrocarbon portion of the oil would indicate that the alleged dacrydene previously reported by Baker and Smith is in all probability identical with Δ^4-carene, and should, therefore, be removed from the literature until evidence of its sep. existence is forthcoming. W. O. E.

Essential oil of Eucalyptus rariflora. A. R. PENFOLD, C. B. RADCLIFFE AND W. F. SHORT. *J. Proc. Roy. Soc. N. S. Wales* **64**, 101–14(1930).—Distn. of the leaves and terminal branchlets of this tree gave a reddish yellow to yellowish brown oil in 2.5% yield, possessing a pronounced phellandrene odor modified by the aromatic aldehydes present. The principal constituents so far identified are the terpenes Δ^4-carene, β-phellandrene, *l*-α-pinene, β-pinene, cymene, with cineole (about 10%), sesquiterpenes (principally aromadendrene), sesquiterpene alcs., with small quantities of the aromatic aldehydes (cuminal, phellandral, cryptal), alkali-sol. compds. (unidentified phenols and dehydroangustione (β-diketone)). The identification of Δ^4-carene is noteworthy in that it is the first record of its occurrence in *Eucalyptus* oils. W. O. E.

Oil of amber. T. TUSTING COCKING. *Perfumery Essential Oil Record* **21**, 477–8 (1930).—An exptl. study is reported of both the true and the com. oils, notably of the consts. obtained in the examn. of the various oil fractions. W. O. E.

Kalk-vizym. HERMANN ESCHENBRENNER. *Pharm. Presse, Wiss.-prakt. Heft*, **1930**, 145–6.—A new vitamin-contg. Ca phosphate prepn. is described, in connection with a review of certain chem. tests for the vitamins A, B and D alleged to be present in the above prepn.

Quinine. KARL DOPF. *Pharm. Presse, Wiss.-prakt. Heft.* **1930**, 167–8.—The history, production and importance of this alkaloid in medicine are discussed. W. O. E.

Examination of pine needle extracts by capillary analysis. H. ESCHENBRENNER. *Pharm. Presse, Wiss.-prakt. Heft* **1930**, 177–8.—A discussion is given of the contaminants not infrequently encountered in com. prepns. of pine needle exts. in connection with a review of the method specified by the Supplement to the D.A.-B.VI, as also that involving examn. of the capillary pictures obtained under the analytical quartz lamp. W. O. E.

Relation of structure to action of morphine and its derivatives. RUDOLF ZIFFERER. *Pharm. Presse, Wiss.-prakt. Heft* **1931**, 1–2.—Attention is directed (by illustration) to

important and valuable derivs. of morphine obtained by means of certain relatively simple changes in its mol. structure. W. O. E.

Sickness and intoxication through benzene and its derivatives. MAX GRÜNEWALD. *Pharm. Presse, Wiss.-prakt. Heft* **1931**, 2–5.—A discussion is given of the intoxication effects of C_6H_6 and derivs. on the animal economy, and of certain precautions to be observed in com. operations with these products. W. O. E.

Reaction of phenylum acetylo-salicylicum. H. SZANCER. *Pharm. Zentralhalle* **72**, 68–9(1931).—It is shown that this substance with $NaNO_2$ and concd. H_2SO_4 yields the same color changes as salol. W. O. E.

Detection of juglone. ROBERT FISCHER AND FRITZ STAUDER. *Pharm. Zentralhalle* **72**, 97–100(1931).—In the microsublimation of *Folia Juglandis* via the D.A.-B.VI. no yellow crystals result, in fact the official Ger. procedure for the microsublimation of either fresh or stored leaves, or of 8-day old, long shredded pericarps, fails to yield juglone. However, extn. with $CHCl_3$ of fresh or 3-day old leaves, followed by suitable treatment of the resulting residue, detects the presence of juglone. Similar results are obtained with 8-day old pericarps. Older leaves are free from juglone. α-Hydrojuglone could not be detected in fresh pericarps. It is shown that the yellowish needles reported by Tunmann as α-hydrojuglone were in reality juglone. β-Hydrojuglone could not be detected in any of the fruit available. W. O. E.

Estimation of *p*-chlorophenol as such and in pharmaceutical preparations. K. FRIST AND F. KLATT. *Pharm. Ztg.* **76**, 112–3(1931).—The method is based on the procedure of Koppeschaar, involving conversion of the *p*-chlorophenol into chlorodibromophenol (by KBr and 0.1 *N* $KBrO_3$ soln. + HCl) followed by treatment with KI, and final titration with 0.1 *N* $Na_2S_2O_3$. In mixts. of *p*-chlorophenol and camphor (or menthol) the former is isolated by treatment with NaOH soln. and then titrated as above. W. O. E.

Chemistry of neodorm. G. KUHLMANN. *Pharm. Ztg.* **76**, 113(1931).—This prepn. is α-bromo-α-isopropyl butyramide; it m. 50 1°, resembles menthol and is sol. in the usual org. solvents and in oil. It decomps. if sterilized in aq. soln., but not in oil. W. O. E.

Adulteration of oil of cloves with benzyl alcohol. S. KROLL. *Pharm. Ztg.* **76**, 128 (1931).—A sample of oil of cloves possessing apparently normal chem. and phys. properties, as stipulated in the Ger. Pharm., was found on examn. to contain considerable $PhCH_2OH$ as adulterant. The presence of this alc. was demonstrated by the method of Thoms (cf Ber. pharm. Ges. **1**, 278(1891)). W. O. E.

United States Pharmacopeial Commission. L. ROSENTHALER *Pharm. Ztg.* **76**, 143–4(1931).—An address indicating the salutary manner in which the Commission operates in marked distinction to the rather secretive activities of similar European bodies. W. O. E.

Manganous calcium hypochlorite. O. H. KÜRSCHNER. *Pharm. Ztg.* **76**, 184–6 (1931).—The reddish color noted from time to time in solns. of Ca hypochlorite is shown to result from conversion of traces of Mn into permanganate. W. O. E.

Production of benzonaphthol and *p*-acetamidophenyl salicylate. JULIUS SCHWYZER *Pharm. Ztg.* **76**, 186–8(1931).—Detailed procedures are reported for the production of benzonaphthol and salophen in large scale operations, in connection with illustrations of the app. needed. W. O. E.

New method for the preparation of isoeugenol from clove oil. R. PRIESTER. *Riechstoffind* **5**, 83–5, 108–9(1930).—Eugenol is converted to isoeugenol (1) by heating with KOH, (2) by the action of KOH dissolved in H_2O, MeOH, EtOH or AmOH under normal or increased pressure, (3) by the action of K or Na amylate in AmOH soln. under ordinary or increased pressure. KOH functions purely as a catalyst. According to the new method eugenol or oil of cloves 30 is heated for 35 min. to about 180° and maintained there 15 min. with H_2O 30, KOH 15, glycerol 5, the mass poured into H_2O, C_6H_6 added, the KOH almost neutralized with dil. H_2SO_4, AcOH added in slight excess, the C_6H_6 soln. withdrawn and washed to neutrality and finally fractionated *in vacuo*. Little or no resinification takes place under the above procedure. W. O. E.

Acetoeugenol and its presence in clove oil. J. HEROLD. *Riechstoffind.* **5**, 100–2 (1930).—The occurrence of acetoeugenol in oil of cloves, its probable fate during the process of distillation, in connection with the various methods for evaluation are discussed. W. O. E.

Composite or unitary perfumes. ERNST SCHIFTAN. *Riechstoffind.* **5**, 119–20 (1930).—The relative advantages of compns. as compared with unitary chem. substances or essential oils are discussed. The decision must be left largely to the expert knowledge of the perfumer. W. O. E.

Chemical and bomb gas baths. W. PEYER AND H. IFFINGER. *Süddeutsche Apoth.-Ztg.* **71**, 77–8(1931).—A general discussion of the essential differences in effect of O and CO_2 bath prepns. when developed from salts with suitable catalyzer directly in the water or indirectly from the capillaries of bombs. It is shown that the former method is the preferable one because of the phys. character of the developed gas. W. O. E.

Native drug plants in the light of modern chemistry and therapy. L. KROBBER. *Süddeutsche Apoth.-Ztg.* **71**, 93–5(1931); cf. *C. A.* **24**, 1934.—An address. W. O. E.

Problems of practical pharmacy. HERMANN THOMS. *Süddeutsche Apoth.-Ztg.* **71**, 110–3(1931); *Pharm. Ztg.* **76**, 195–9.—An address. W. O. E.

American medical plants of commercial importance. A. F. SIEVERS. U. S. Dept. Agr., *Misc. Publ.* **77**, 1–74(1930).—About 1580 plants of reputed medical value are described. C. R. FELLERS

Assay of digitalis. II. Comparison of Mansfeld's sinus method with the six-hour frog or cat method. A. STASIAK AND B. ZBORAY. *Magyar Gyógyszerésztud. Társaság Értesitöje* **5**, 400-6(1929); cf. *C. A.* **23**, 4770.—Further investigations were made by the method of Mansfeld-Horn on spring frogs with powders of digitalis leaves. An infusion made according to Mansfeld was used as standard. Parallel detns. on the same powder agreed well. The differences between the results of the sinus method and those of the 6-hr. frog or cat method are the same as those of the frog method and the cat method between each other. S. S. DE FINÁLY

Extractum filicis maris. Z. CSIPKE. *Magyar Gyógyszerésztud. Társaság Értesitöje* **5**, 425-38(1929); cf. *C. A.* **23**, 4769.—No correlation can be found between biol. losses of value and quantity of active matter found by chem. methods. Results of the so-called "pure filicic acid" detns. (Fromme, Kraft) are unreliable, since they do not show the presence of lower phloroglucides which also have anthelmintic power. A modification of the method of Kraft-Boechi-Fromme has been worked out. Shake out the ether soln. of the ext. twice with baryta water, and filter. Treat an aliquot part of this soln. with ammoniacal $AgNO_3$ soln Let stand for 6–10 hrs. in a dark place. Filter out the reduced metallic silver, wash, dissolve in 20% HNO_3, and titrate with 0.1 *N* NH_4SCN soln. One cc. of this soln. equals 0.00217 g. phloroglucinol or 0.0196 g. phlorobutyrophenone. S. S. DE FINÁLY

Biological evaluation of extracts of Filix mas. Z. CSIPKE. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 85-101(1930); cf. preceding abstract.—Chem. evaluation alone is not reliable. Biol. tests can be made satisfactorily with *Hirudo medicinalis* and *H. officinalis*. An emulsion of the drug with 1% $NaHCO_3$ was used. Exts. kept closed from the air remain undecompd. for years. For the test 4 g. of the ether ext. is shaken carefully at 40°, and mixed with powd. gum arabic and 1% aq. $NaHCO_3$ to an emulsion. This is dild. with 1% $NaHCO_3$ to 2000 cc. Of this dild soln. 500 cc. (equal to 1 g. ext.) is again dild. with $NaHCO_3$ soln. to 2000 cc. The soln. can be used after 2 hrs. M. l. d. is detd. with three series of expts. One series for orientation, the third for actual detn. M. l. d. found was 0.0028 in 100 cc The animals should be kept in motion under the detn. by mechanical or elec. means. S. S. DE FINÁLY

How to distinguish sulfonal from trional. L. EKKERT. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 385–6(1930).—The substance to be tested is heated with resorcinol and concd. H_2SO_4 until it shows a green color. The liquid is dild. and NH_3 added. Sulfonal shows bright rose color; trional becomes brownish yellow or reddish brown. S. S. DE FINÁLY

Biological test of adrenaline in draft mixtures, especially in the presence of local anesthetics. A. STASIAK AND L. RIGÓ. *Maygar Gyógyszerésztud. Társaság Értesitöje* **6**, 389–95(1930).—The presence of adrenaline can easily be proved in mixed draughts, even in presence of local anesthetics, by means of surviving mouse uterus. Adrenaline prevents the spontaneous contractions of the surviving uterus. These contractions, however, reappear very quickly after the uterus is washed out with Locke's soln. Thus the same uterus may be used for several detns. By this method adrenaline can be detected in the presence of novocaine, β-eucaine, holocaine, percaine, stovaine and tutocaine and in the presence of ext. of posterior lobe of the hypophysis. Novocaine increases the sensitiveness of surviving mouse uterus to adrenaline; β-eucaine and stovaine diminish it. Holocaine showed no influence on the sensitiveness. S. S. DE FINÁLY

Comparative studies on the tannic acid content of some drugs. I. TEMESVARY. *Magyar Gyógyszerésztud. Társaság Értesitöje* **6**, 396–402(1930).—Of the methods studied, (1) international hide-powder method, (2) Löwenthal method, (3) $SnCl_2$ method, (4) Wasicky method, (5) Schulte method and (6) tannoform method, (1) gives the most exact and reliable results. However, this gives high values for cinchona bark (part of

alkaloids is dissolved and pptd. by skin-powder) and for *Rheum* (where much slime is attached to the hide-powder). The tannoform method can usually be used when pyrocatechol-tannic acid is present. S. S. DE FINÁLY

Stability and attenuation of insulin. H. PUIGGARI. *Rev. soc. argentina biol.* **5**, 677–84(1929); *Physiol. Abstracts* **15**, 239.—Attenuation is avoided by the concn. of the alc.-acid exts. of pancreas *in vacuo* at 35–40°. Controls were made 200 days later, and no loss of pharmacol. activity was found. G. G.

New assay method and identification tests for mild and strong silver proteinate. I. H. INABINETTE. *Am. J. Pharm.* **103**, 42(1931).—Tanret's soln. produces a flocculent yellow ppt. when added to an equal quantity of 1% soln. of strong Ag proteinate. With the mild Ag proteinate a flocculent grayish black ppt. is given. Nessler's reagent is even more distinctive when used under the same conditions. A clear, golden brown soln. is produced with the strong Ag proteinate and bluish black soln. with the mild proteinate. Both of these solns. were satisfactory identifying agents for protargentum, protargol, Ag protein, Merck and P. W. R., argyrol, solargentum and argo nuclein (S. K. F. Co.). A new assay method, much more rapid than the present U. S. P. X, is as follows: Weigh 0.5 g. of the Ag compd., dissolve in 20 cc. H_2O, then add 20 cc. concd. HNO_3 and boil for 10 min. Cool, dil. to about 150 cc. and titrate with 0.1 *N* KCNS, using ferric alum as an indicator. This method produced results identical with those obtained by the U. S. P. X method. W. G. GAESSLER

Assay of solution of magnesium citrate. HERMAN W. HAUSSMANN. *Am. J. Pharm.* **103**, 44–5(1931).—The present method of the U. S. P. X for Mg requires evapn. and ignition, a time-consuming operation and one in which error may arise. The following modification of this gives slightly higher but more consistent results: The material after detn. of the free acid is evapd. and ashed as usual. The ash is then transferred to a porcelain dish with hot water and 50 cc. of 0.5 *N* H_2SO_4 added. It is then boiled, cooled and the excess of acid detd. by titration against 0.5 *N* NaOH with Me orange as indicator. W. G. GAESSLER

Assay method for ointments containing mercury or its salts. R. O. METZLER. *Am. J. Pharm* **103**, 45(1931).—For mercurical ointments the present method as outlined in the U. S. P. X gives satisfactory and consistent results. For calomel ointment weigh about 1 g. of the ointment directly on a dense filter paper. Fold and pass CCl_4 through until all fat is removed. Place the paper in a glass-stoppered flask, add 10 cc. CCl_4, 30 cc. 0.1 *N* I, 3 g. KI and 10 cc. H_2O. Shake well, allow to stand 12 hrs. and det. excess 0.1 *N* I with 0.1 *N* $Na_2S_2O_3$. Twelve detns. gave results varying from 30.09% to 30.5% calomel. For yellow HgO ointment the following methods were used: (1) Boil with HNO_3, add H_2O and titrate with 0.1 *N* KCNS. (2) The same as No. 1 except fat is filtered off before titration. (3) Treat as in No. 2 and ppt. Hg as sulfide. (4) Destroy fat with concd. H_2SO_4 and $KMnO_4$ and det Hg as sulfide. None of these methods gave results which were consistent or in agreement with the known compn. of the specially prepd. yellow HgO ointment. W. G. GAESSLER

Determination of boric acid in ointment of boric acid U. S. P. X. THEODORE BUDIN. *Am. J. Pharm.* **103**, 46(1931).—Place 25 cc. $CHCl_3$, 10 cc. glycerol and 1 cc. of phenolphthalein test soln. in a well-stoppered container. Shake, add 0.1 *N* alkali to faint pink color. Then introduce about 1 g. of boric acid ointment weighed on a wax paper, and add 25 cc. of 0.1 *N* NaOH. Shake well and det. excess of NaOH by titration with 0.1 *N* H_2SO_4. W. G. GAESSLER

Investigation of calcium hypochlorite (65 percent available chlorine). BERNARD MELKON. *Am. J. Pharm.* **103**, 46(1931).—Analysis of a com. supply of a product marketed under the trade title H. T. H. by the Mathiesen Alkali Works, Inc., gave insol. in H_2O 8.40, SiO_2 0.28, Fe_2O_3 0.38, Al_2O_3 1.76, CaO 32.17, available Cl 62.70%. W. G. GAESSLER

Assay of chloroform liniment. JOHN C. BRANTLEY, JR. *Am. J. Pharm.* **103**, 46–7(1931).—The method of Willgerodt (*C. A.* **20**, 92) was compared with a direct standard alkali sapon. and titration of residual alkali. Direct alkali sapon. does not give correct results. W. G. GAESSLER

Development of pharmaceutical chemistry in Maryland. A. G. DUMEZ. *J. Chem. Education* **8**, 471–84(1931). E. H.

The hydroxylamine method for the determination of ketones. Carvone in caraway and dill oils. C. T. BENNETT AND T. TUSTING COCKING. *Analyst* **56**, 79–82 (1931).—The method of Bennett and Salamon (*C. A.* **22**, 1825) applied to various oils contg. aldehydes and ketones does not give satisfactory results in all cases; the method must be modified according to the particular ketone present. The modified method of the Essential Oil Sub-Committee for the detn. of citral in oil of lemon (*C. A.* **24**, 1934) is

of almost universal application for testing oils contg. aldehydes, if a little benzene is added as solvent for the non-aldehydic portion of the oil; but this modified procedure was found to be quite unsuitable for the detn. of ketones. After considerable experimentation with dill oil, caraway oil, pennyroyal and piperitone, the following modification of the method was adopted for detg. carvone in oils of dill and caraway. Weigh 1.5 g. of oil into each of 2 stoppered tubes, add 10 cc. of approx. *N* NH_2OH·HCl reagent (6.95 g. dissolved in 95 cc. of 90% alc., 0.4 cc. of 0.2% dimethylyellow added and sufficient *N* KOH in alc. to bring the soln. to a full yellow), and heat in boiling water to about 75°. The color of the soln. changes from yellow to red, as a result of liberation of HCl. At 5-min. intervals remove each tube from the water bath and neutralize with *N* KOH in alc., using a sep. buret for each sample. Toward the end, the indicator becomes golden orange instead of red and it is hard to estimate the exact end point. When it is thought that the end of the reaction has been reached, add 0.5 cc. more of KOH to one of the tubes to overstep the end point and add to the other sufficient NaOH to match the color in the other tube. In the computation, 1 cc. of *N* KOH = 0.1513 g. of carvone. The advantages of this method over that of the neutral sulfite method are that very little oil is required and less time. The method has been applied to the detn. of ketones in other oils (menthone in oil of peppermint and pulegone in oil of pennyroyal) but the end point was hard to see. W. T. H.

Seventh report of the essential oil sub-committee on uniformity of analytical methods. Determination of solubilities. J. Allan *et al.* *Analyst* **55**, 386(1930).—The tests should be carried out at 15.5°, unless stated otherwise The concn. of alc. should be given in % by vol. and the following terms should be used as defined in the report: sol., sol. with opalescence, sol. with turbidity. Regarding the opalescence and turbidity, the adjectives *faintly, slightly* and *distinctly* should be used with reference to expts. under stated conditions with AgCl (for opalescence) and with $BaSO_4$ (for turbidity). W. T. H.

Testing of Admiralty disinfectant fluid. T. C. Patterson and Robert C. Frederick. *Analyst* **56**, 93–104(1931).—Two disinfectant fluids were divided into 2 series of identical samples and the phenol coeff. by the Rideal-Walker method was detd. in 13 different labs. The values obtained for one sample ranged from 6.0 to 11.5 and on the other from 6.0 to 17.4. To avoid such discrepancies, the Admiralty method is described in great detail. The method consists in prepg. a 1% diln. of the fluid with artificial sea water, allowing this to stand 24 hrs. and then comparing its action in the presence of org. matter against a particular strain of *B. typhosus* with similar expts. with pure phenol used as reference. A bibliography of 19 titles is appended. W. T. H.

Chloretone as a preservative. B. Polák. *Bratislav. Bekarske Listy* **9**, 281–4 (1929).—Chloretone (Cl_3CCMe_2OH), which is used as a preservative of org. substances, is injurious to the circulation by its paralyzing effect on the heart muscle and motor cardiac centers. William J. Husa

Distillation of essential oils. V. G. Patwardhan. *Poona Agr. Coll. Mag.* **21**, 31–3 (1929).—An app. for the small scale distn. of essential oils from grasses, etc., is described and illustrated. Two to 5 lb. of material, depending upon its nature, can be distd. at one time. K. D. Jacob

Merthiolate as a germicide. H. M. Powell and W. A. Jamieson. *Am. J. Hyg.* **13**, 296–310(1931).—*Merthiolate* (I) is *Na ethylmercurithiosalicylate*, $EtHgSC_6H_4CO_2Na$; a study was made of the general properties, germicidal and inhibition properties and toxicity for animal tissues. I is a white, orthorhombic cryst. compd., readily sol. in water and physiol. salt soln. Solns. of germicidal strength are stable under ordinary conditions of light and temp., are colorless and do not stain tissues or fabrics. The aq. solns. are miscible with soap and maintain their germicidal property. I does not amalgamate with metals. In soln. it is so slightly ionized that there is no immediate pptn. of Hg with either alk. hydroxides or $(NH_4)_2S$. Dry I or aq. I can be mixed in various proportions up to 25% with undild. serum without causing pptn.; I is pptd. by the salts of heavy metals and by acids. Many germicidal tests were made and are reported; from these tests it appears to be a very promising germicide with certain unusual properties which make it well adapted to tissue antisepsis. N. A. Lange

Estrogenic substances. II. Analysis of plant sources. Burnham S. Walker and James C. Janney. *Endocrinology* **14**, 389–92(1930); cf. *C. A.* **24**, 3809.—A relatively high concn. of estrogenic material occurs in plants associated with green pigmentation. Roots, tubers and fruits are neg. Estrogenic substances in yeast are an exception. Pos. extracts are obtained from plants while their growth is most rapid. Mary E. Lear

Chemical analysis of the cortex of Aspidosperma polyneuron Müell. Arg. Louis

FLORIANI. *Ann. Farm. Bioquim.* **1**, 135–9(1930).—F. made a modification of the procedure of Arata and with its aid found that the cortex of *Aspidosperma polyneuron* Müell. Arg. contained 2% of alkaloid. The nature of the alkaloid is under study.
B. S. LEVINE

Studies on the Vitali reaction for the detection of atropine. I. The extent of its applicability. SANTIAGO A. CELSI. *Ann. Farm. Bioquim.* **1**, 140–9(1930).—A study of the Vitali reaction as applied to atropine-HCl or sulfate, hyoscyamine, scopolamine, isatropylcocaine, homatropine and other alkaloids. The relation between the reaction and the chemical constitution of the reacting substances is discussed. The Vitali and Arnold reactions are compared.
B. S. LEVINE

Physiological styptics. OSKAR BEYER. *Chem.-Ztg.* **54**, 1007(1930).—A review of the various styptic agents is made. It is suggested that a rational means of stopping bleeding is to strengthen artificially by catalytic agents, the formation of thrombin. A prepn. of this type would be useful in hemophilia and in patients suffering from jaundice and liver damage. Such a prepn. is made from cow liver. Finely ground fresh cow liver, 300 g., is placed in a 2 l. flask; one l. of 96% alc. is added and the contents are extd. for 30 min. at about 60° on a water bath. The bright yellow liquid is rapidly filtered off on a porcelain suction filter. The filtrate treated with 4 portions of pure ether is allowed to stand 8–12 hrs. at room temp. The ether soln. is decanted, leaving a yellowish brown mass adhering to the walls of the vessel. The flask is heated to about 30° and the ether removed *in vacuo*. The residue, about 25 g., is taken up in 300 cc. sterile water, filtered, and 5 cc. put in sterile glass ampules. The ampules, after sealing, are sterilized in steam at about 95° for ½ hr. The soln. is assayed for clotting power. The substance contains N, peptones, amino acids, purine bases and carbohydrates.
G. H. W. LUCAS

Constitution of amino alcohols as local anesthetics. (Supplement.) S. KANAO AND K. SHINOZUKA. *J. Pharm. Soc. Japan* **50**, 1152–62(1930); German abstr. 148–52; cf. *C. A.* **24**, 3832.- In previous papers K. reported on the type I, $RCH(OH)CHR'(NR''R''')$. The present paper deals with the type II, $RR'C(OH)CH_2NH_2$. The local anesthetic action is neg. if R and R′ are both Me, Et or Pr; it is pos. if R and R′ are both Bu, $Me_2CHCH_2CH_2$, Ph or $PhCH_2$, or if R is Bu or cyclohexyl and R′ is Ph. The methods of prepn. of these amino alcohols are also given
F. I. NAKAMURA

Semen contra pills. J. MAHEU AND J. CHARTIER. *Ann. fals.* **23**, 613–4; *J. pharm. chim.* [8], **12**, 301–3(1930); cf. *C. A.* **21**, 2961.- Examn. of 4 samples for alkaloids, heavy metals, cyanogenetic glucosides and santonin gave neg. results, and the seed contained in each pill had all the morphological and anatomical characteristics of lucern
A. PAPINEAU COUTURE

Pyrethrum flowers from Kenya and Cyprus. ANON. *Bull. Imp. Inst.* **28**, 425–9 (1930). -Samples of pyrethrum grown in Kenya and in Cyprus were found to be of nearly as good quality as the best Dalmatian pyrethrum.
A. PAPINEAU-COUTURE

Tetrapone. H. BAGGESGAARD-RASMUSSEN. *Archiv Pharm. Chemi* **38**, 29–37 (1931). -Mixts. of alkaloid hydrochlorides have come into use in Danish hospitals. One contains morphine 50, narcotine 19.4, codeine 3.2, papaverine 4.5, thebaine 1.7 and narceine 0.8%. In another one thebaine and narceine are omitted and the narcotine is increased to 22%. The names "hexapone" and "tetrapone" are recommended for these as in line with Roche's "pantopone."
A. R. ROSE

Tinctura Quillajae and Liquor carbonis detergens. K. A. KARSMARK AND L. KOFLER. *Svensk Farm. Tids.* **34**, 706–14(1930)(in German).—The tincture made with 62% alc. contained 5 times more saponin than that made with 86%. Quillajae tincture with 42% alc. contained less sediment than the 62% prepn. The 62% alc. prepn. is to be preferred in making Liq. carbonis detergens. Percolation is better than trituration.
A. R. ROSE

Sublimated or synthetic benzoic acid in preparing mucilago gummi arabici and sebum salicylatum. HUGO WASTENSON. *Svensk Farm. Tids.* **34**, 714–5(1930).—The next edition of the pharmacopoeia should specify synthetic PhCOOH where it now specifies sublimated.
A. R. ROSE

The constitution and constants of sandal oil. R. CAJOLA. *Rivista ital. essenze profumi* **12**, XXI(1930).—This essence is obtained by distg. *Santalum album* wood. It is a yellow limpid liquid, with an agreeable persistent odor and an irritating acrid resin taste; it has sp. gr. 0.975–0.985 and boils and distils at 275–300°. The oil is sol. in all proportions in 90° alc., and has 90–98% of *a*- and *b*-santalol, with *a*- and *b*-santalene ($C_{15}H_{24}$), santene (C_9H_{14}), santenone ($C_9H_{14}O$), santenone alc. ($C_9H_{16}O$) and traces of santalic acid ($C_{15}H_{24}O_2$) and teresantalic acid ($C_{20}H_{14}O_2$) and a santal aldehyde ($C_{15}H_{24}O$). Sandal oil is used in medicine in mixt. with other sedative and antiseptic substances, and

constitutes the principal curing element in many pharmaceutical compds. It is used in doses of 1.5–2 g. per day for initiating the cure of blennorrhagia, when other antiseptics cannot be used in inoculations because of the irritation of the mucose. It is also useful in bronchial complications, as it is eliminated with the urine and during breathing. R. SANSONE

The composition and properties of sassafras and its essential oil. R. CAJOLA. *Rivista ital. essenze profumi* **12**, XXII(1930).—The wood of the sassafras plant contains the coloring principle sassafride and tannic acid. Its medicinal uses are listed. The roots contain balsamic resin, wax, sebaceous matter, tannic acid, coloring matter, gum, albumin, starch and 2.5% of a yellow essential oil. This oil is very little sol. in alc., it contains safrene ($C_{10}H_{16}$), an alc., safrole and a volatile phenol-like substance. R. SANSONE

The properties and composition of mustard seed. R. CAJOLA. *Rivista ital. essenze profumi* **12**, XXII-XXIII(1930).—Mustard seeds contain 20% of mucilage and 30% of a sweet fatty oil, the alkaloid sinapine, the enzyme myrosin, and sinigrin. Powd. mustard seeds, when beaten with lukewarm water, develop a chem. action between the myrosin and sinigrin, producing glucose, $KHSO_4$ and allyl isothiocyanate. With boiling water the reaction does not take place. The uses of mustard-seed oil are listed. R. SANSONE

A study of the treatment for insomnia. HENRI FAVIER. *Thesis*, Montpellier, 1929; *J. pharm. Alsace Lorraine* **57**, 200(1930).—A monograph on the hypnotic action of *sedormid* (cf. *C. A.* **22**, 3929). S. WALDBOTT

Pharmacy in Syria. C. LADAKIS. *Bull. Sud-Ouest et du Centre; J. pharm. Alsace Lorraine* **57**, 213–4(1930).—An account of present conditions under French administration. S. WALDBOTT

"Virtual adrenaline" in relation to inactivation of adrenaline by formol. MARCEL PAGET AND CHARLES P. LEBLOND. *J. pharm. chim.* [8], **12**, 531–6(1930); cf. *C. A.* **24**, 3323–4.—When the :NH function of adrenaline (*A*) is blocked by means of formol, the Denigès reaction becomes neg., but the reactions which are sp. for the pyrocatechol nucleus (Vulpian; Folin; P., cf. *C. A.* **25**, 532) remain pos. Blocking the :NH function diminishes considerably the mydriatic power of *A* without destroying it entirely. It sheds no light on the nature of "virtual *A*"; work on this subject is in prepn. S. W.

Oxidation of official castor oil by potassium permanganate. Study of triazelain. G. SCHUSTER. *J. pharm. chim.* [8], **13**, 5–12(1931).—The principle of the Hilditch method is applied (cf. *C. A.* **22**, 944, 2477, 3792, etc.). By $KMnO_4$ oxidation in acetone soln. of official castor oil, 63.58% triazelain (*A*) was formed. After sapon. of crude *A*, neither stearic nor dihydroxystearic acid was obtained. The results of Heiduschka and Kirsten (*C. A.* **24**, 1933) indicated these compds. were present. The same oil to which 3% of stearic acid was added yielded this quantity after oxidation; hence the sample examd. contained no glycerides of satd. acids. *A* was also synthesized by the action of epichlorohydrin of glycerol upon acid Na azelate ($CO_2H(CH_2)_7CO_2Na$) in sealed tubes at 135–140°. With a neutral 2% soln. of the Na salt of *A*, $AgNO_3$ forms a brick-red ppt. not altered by light; solns. of $BaCl_2$, $Bi(NO_3)_3$, $CdSO_4$ and $Sr(NO_3)_2$ give a chamois-yellow; $CuSO_4$ gives a green ppt.; $MgCl_2$ produces a chamois-yellow ppt. while Mg azelate is H_2O-sol. By means of this reaction, *A* was purified. S. WALDBOTT

Herba equiseti, a saponin-bearing drug. P. CASPARIS AND K. HAAS. *Pharm. Acta Helv.* **5**, 62–3(1930).—The presence of saponin in the herb was proved by foam no. expts. on a 10% chlorophyll-free decoction and a 10% aq. soln. of a purified MeOH dry ext., and also by the hemolytic effect of 1% of the latter soln. S. WALDBOTT

Senegin and its decomposition products. O. DAFERT AND E. KALMAN. *Pharm. Acta Helv.* **5**, 71–7(1930).—By extg. senega root repeatedly with 96% alc. and evapg. to a small bulk, crude neutral saponin (senegin) is pptd. (yield 10%). By repeated pptn. from soln. in 80, 90 and 96% alc., 3–4% pure H_2O-sol. senegin contg. C 52.29%, H 7.17% is obtained. It is hemolytic in dilu. of 1:66,000. Hydrolysis with 5% H_2SO_4 and then 5% alc. H_2SO_4 for 30 hrs. yielded a substance identical with that examd. by Wedekind and Krecke (*C. A.* **18**, 3362). Other products of hydrolysis are dextrose (41.09%), which seps. at first, then methylpentose (11.12%) and arabinose (11.06%) are split off (cf. Winterstein and Maxim, *C. A.* **13**, 1213). A list of 21 references is added. S. WALDBOTT

The evaluation of tribromophenol bismuth gauze. RUD. G. MAEDER. *Pharm. Acta Helv.* **5**, 112–6, 151(1930).—Weigh 4–5 g. of gauze exactly, add 20 cc. of 25% HCl, knead the gauze with a glass rod, add 50 cc. hot H_2O, knead again, transfer the soln. into a 200-cc. flask and repeat the extn. with 5 × 30 cc. hot H_2O. Cool, filter off the sepd. $C_6H_2(OH)Br_3$ and in the filtrate ppt. Bi with H_2S. Collect the Bi_2S_3 on a small filter,

wash with 2 × 10 cc. H_2O and dissolve the ppt. on the filter by adding, drop by drop, 15 cc. HNO_3 (d 1.4). Wash the filter with 3 × 10 cc. H_2O and warm on a steam bath to expel H_2S completely. Cool, then add in small portions 25 cc. NH_4OH (20–25%), collect the $Bi(OH)_3$ on an ash-free filter, wash well, dry at 103–105° and ash in a porcelain crucible. When cool, add a few drops of fuming HNO_3, evap. on a water bath, then heat slowly with a flame, finally to red heat, cool in a desiccator and weigh. Multiply the wt. of Bi_2O_3 bv 2 to obtain the wt. of *"xeroform"* in the gauze (com. xeroform yielded 49.6 and 55.2% Bi_2O_3; 50% is the standard adopted). In 5 com. samples of gauze, marked 20%, 10, 10, 5, 5%, the method showed 16.0%, 6.4, 6.9, 4.37 and 2.95%, resp. Deviations from statements on the label must not exceed ±10%. S. WALDBOTT

Pilulae ferratae Blaudii. J. B. LANG. *Pharm. Acta Helv.* **5**, 121–3(1930); cf. *C. A.* **24**, 5110.—The pharmacol. results of Starkenstein (*C. A.* **21**, 1494) confirm L 's contention that Blaud's pills should be as free as possible from ferric salt. The following modification of the previous test is given: Triturate 1 pill with 0.3 g. $BaCl_2$, mix with 20 cc. H_2O and filter. Divide the clear filtrate into 2 equal parts; to 1 add 5 drops of $K_3Fe(CN)_6$ soln.; a deep blue ppt. is formed at once. To the other add 5 drops of $K_4Fe(CN)_6$ soln.; at most a light blue coloration may appear. This test does not apply to pills consisting mostly of $FeCO_3$. S. WALDBOTT

Note on the Pharm. Ned. V. test for codeine in papaverine hydrochloride. E. ANNELER. *Pharm. Acta Helv.* **5**, 124(1930).—The following requirement of Pharm. Ned. V. is probably based on error: "The soln. of 10 mg. papaverine-HCl in 1 cc. H_2SO_4 shall be colorless or at most faintly yellowish; upon adding 1 drop of $FeCl_3$ soln. and warming on the water bath, no violet color must form (codeine)." The violet color which at first is pale green is produced with papaverine itself; this fact was proved with samples of known purity, and with papaverine prepd. synthetically. S. WALDBOTT

Determination of polysulfide and preparation of calcium sulfuratum solutum (Vlemingkx solution). J. BÜCHI. *Pharm. Acta Helv.* **5**, 124–32(1930).—The exact and rapid method of Schulek for the detn. of polysulfides (*C. A.* **19**, 1829) is adopted in the new Pharm. Helv. V. This method enables a much-needed control of the compn. of Vlemingkx soln. (*A*). When prepd. according to the directions of different pharmacopeias including Pharm. Helv. IV, *A* will contain very variable quantities of polysulfides. To prep. *A* of const. compn., the formula adopted by Pharm. Helv. V is recommended: Slake 1 part CaO with 5 parts H_2O, then add 2 parts of washed S and 10 parts H_2O. Boil the mixt. for 1 hr. under reflux (to exclude the air), cool, decant and pour through cotton. The sp. gr. of *A* thus prepd. is 1.12–1.14; the content of polysulfide S is 60–65 g. per l. A list of 8 references is added. S. WALDBOTT

The galenical preparations of Pharmacopeia Helvetica V. K. SIEGFRIED. *Pharm. Acta Helv.* **5**, 255–70(1930).—An address. Among novel requirements demanded by the Pharm. of Swiss pharmacies are a standardized thermometer, an app. for evapg. exts. under reduced pressure, special vessels to keep drugs and exts. over lime, a polariimeter and a polarization attachment to the microscope. Certain emulsions, *e. g.*, of P, must be prepd. with stabilized, *i. e.*, enzyme-free gum arabic. The new features of all galenical prepns., *e. g.*, the various exts., infusa, injectabilia, tinctures, ointments, etc., are discussed. S. WALDBOTT

The examination of alkaloids for purity in the Swiss pharmacopeia. R. EDER, E. BÜRGI AND H. T. LIEM. *Pharm. Acta Helv.* **5**, 276–85(1930); cf. *C. A.* **24**, 5424.—An address. The various pharmacopeias should agree on a uniform definition of alkaloids, *e. g.*, in quinine sulfate. The reaction of alkaloidal salt solns. should be measured by detg. the p_H value by means of colorimetric indicators. A list of 25 such salt solns. has been arranged into 6 groups of varying p_H values (2.8–7.0). S. WALDBOTT

The use of *p*-hydroxybenzoic esters in sterilization and disinfection. TH. SABALITSCHKA. *Pharm. Acta Helv.* **5**, 286–8(1930); cf. *C. A.* **22**, 2029; **23**, 2733; **24**, 160, 3285, 4834, 5886; **25**, 1031.—The antiseptic and sterilizing effect of 0.05% of ***nipasol*** (*A*), the Pr ester of *p*-$OHC_6H_4CO_2H$, exceeds that of a 0.25% PhOH soln. E. Leschke found 0.04% of *A* or 0.2% of the sol. Na compd. completely non-toxic and non-irritating in injections. The 0.2% soln. is recommended for sterilizing instruments, and to keep medicaments sterile for internal therapy. *A* and the similar esters may also be used for disinfecting powders, *e. g.*, $B(OH)_3$. talcum; warming with 1–3% Me ester, or 2–6% mixed esters to 70°, renders these powders germ-free for at least 2.5 yrs. Addn. of these esters enhances the antiseptic effect of $B(OH)_3$ materially. S. WALDBOTT

A comparison of certain suspending agents. F. R. C. BATESON. *Pharm. J.* **126**, 52–3(1931).—Shake a suspension of 2 g. prepd. chalk in 100 cc. water for 30 min. with (*a*) 12.5 cc. of mucilage of gum acacia (*Brit. Pharm.*), (*b*) 12.5 cc. of mucilage of tragacanth, (*c*) 2.22 g. of compd. powder of tragacanth, (*d*) 3.33 g. of the same, then pour off

50 cc. of the suspensions and det. $CaCO_3$ in each suspension and residue. It is found that the most efficient suspending agent for insol. powders is *compd. powder of tragacanth* (*Brit. Pharm.*). The (above) proportion of 10 grains is but slightly less effective than 15 grains per fluid ounce, but as in the latter case the mixt. is very viscous, the weaker proportion is preferable. The 2 mucilages (*a* and *b*) are not nearly so effective as suspending agents. S. WALDBOTT

The leaf oils of Washington conifers. Introduction. ARNOLD J. LEHMAN AND E. V. LYNN. *J. Am. Pharm. Assoc.* 19, 840–3(1930).—Botanists list 21 species of conifers in the state. The oils from 8 have been studied previously by others. The introduction contains a review of the literature and bibliography. L. E. WARREN

Physiological potency of commercial ergot preparations. W. T. MCCLOSKY, M. R. THOMPSON AND N. G. BARBELLA. *J. Am. Pharm. Assoc.* 19, 844–7(1930).—A survey was made of the market supply of fluidext. of ergot and other ergot prepns. The prepns. were tested by the cockscomb method but if the results were not concordant checks were run by the Brown-Clark method as modified by Pattee and Nelson. The fluidexts. assayed 0–400% of the U. S. P. requirements. The other prepns., many of which were in ampoule form, assayed from 0 to about 120% of the labeled amts. The assay methods used are capable of detg. the specific alkaloidal activity within ±20%. Therefore those prepns. assaying 80–120% of the U. S. P. X potency may be considered as satisfactory. Of 79 com. fluidexts. 35% were substandard, 20% were of U. S. P. potency and 45% were superstandard. Many of the substandard prepns. had been repackaged before final marketing. Probably some of the superstandard prepns. had been assayed by the U. S. P. method immediately after making and the non-specific amine interference had instituted an error in standardization. Such errors in standardization may be avoided by aging the prepns. in filled containers for several months before final standardization. Com. ergot prepns. should bear an expiration date. L. E. WARREN

Oleonaphtha as absorber of ethereal oils from distillation water. V. I. VARENTZEV. *J. Chem. Ind.* (Russia) 6, 966–7(1929).—Instead of following the usual procedure of returning the condensed distd. water holding droplets of ethereal oils back to the distg. app. the condensate collecting in the traps is made to pass through a layer of oleonaphtha, which retains the ethereal oils. A saving of 1.77% of the product was accomplished by this innovation. This method was also successfully applied to the recovery of *terpineol* from condensate, increasing the recovered product by 3.33%. A. C. Z.

Ambergris and how to recognize it (MORRISON) **27.** Analysis and preparation of medicated soaps (MATOLCSY) **27.** The economics of pyrethrum (GLASSFORD) **15.** Pyrazolone derivatives [intermediates for drugs] (Ger. pat. 514,421) **25.** Immunizing plants [vegetable serums for human and veterinary therapeutics] (Fr. pat. 693,723) **15.** Creams, etc. (Fr. pat. 692,454) **27.**

GILDEMEISTER, E., AND HOFFMANN, FR.: **Die ätherischen Öle. Band III.** 3rd ed., revised by E. GILDEMEISTER. Miltitz bei Leipzig: Verlag der Schimmel & Co. Akt. M. 36; half-leather, M. 40. Cf. *C. A.* **24,** 690.

TRUTTWIN, HANS: **Grundriss der kosmetischen Chemie.** Brunswick: Vieweg. 152 pp. M. 9.75.

Synthetic drugs. I. G. FARBENIND. A.-G. (Erich Bartholomäus, inventor). Ger. 514,418, Apr. 28, 1928. Anthelmintics of a basic character are prepd. by treating ketotetrahydronaphthalenes with CH_2O and a secondary amine. Thus, an alc. soln. of 1-ketotetrahydronaphthalene, paraformaldehyde and $Me_2NH.HCl$, boiled under reflux for 1 hr., yields *2-dimethylaminomethyl-1-ketotetrahydronaphthalene-HCl*, m. 158–9°. Other examples are given also.

Synthetic drugs. I. G. FARBENIND. A.-G. (Hans Schmidt, inventor). Ger. 515,206, Nov. 7, 1928. Sol. complex org. compds. of Sb are prepd. by the reaction of aromatic *o*-dihydroxy compds. contg. acid salt-forming substituents or their salts, with oxygenated compds. of quinquevalent Sb. Thus, an aq. soln. of K catecholdisulfonate may be treated with an excess of antimonic acid and the soln. filtered and neutralized; the product is pptd. by pouring into MeOH. Other examples are given also.

Synthetic drugs. I. G. FARBENIND. A.-G. (Karl Streitwolf, Alfred Fehrle and Hubert Oesterlin, inventors). Ger. 515,207, Aug. 28, 1929. Addn. to 510,451 (*C. A.* 25, 1036). The method of prepg. arsenobenzenes having aromatic hydroxyacylamino groups described in Brit. 318,491 (*C. A.* 24, 2241), is modified by condensing one component in the form of its arsine with the other component in the form of its arsine oxide

or the corresponding dichloroarsine. Thus, 4-glycolylaminobenzenearsine oxide in alc. HCl soln. may react with 3-amino-4-hydroxyphenylarsine. Other examples are given also.

Synthetic drugs. I. G. FARBENIND. A.-G. (Fritz Mietzsch and Heinrich Klös, inventors). Ger. 515,466, Jan. 30, 1929. New products effective against blood parasites are prepd. by acylating 4-(ω-aminoalkyl)aminobenzenearsonic acids, which may or may not be substituted in the 2-position. The initial materials may be prepd. as described in Ger. 501,088 (*C. A.* **24**, 4588-9). Examples are given.

Synthetic drugs. SCHERING-KAHLBAUM A.-G. (Adolf Feldt, Walter Schoeller and Erich Borgwardt, inventors). Ger. 513,799, May 6, 1926. Addn. to 511,303. The method of Ger. 511,303 (*C. A.* **25**, 1335) is extended to the conversion of aminometalmercaptosulfonic acids generally into the corresponding ω-sulfomethylamino compds. The initial materials in two of the examples given are Na β-amino-α-auromercaptoethanesulfonate and Na 3-amino-4-auromercaptobenzenesulfonate

Synthetic drugs. SCHERING-KAHLBAUM A.-G. (Walter Schoeller and Erich Borgwardt, inventors). Ger. 514,506, Feb. 12, 1926. Addn. to 506,443. The method of prepg. auromercapto acids described in Ger. 506,443 (*C. A.* **25**, 381) is modified by using acid or neutral sulfite in place of H_2SO_3. Examples are given.

Synthetic drugs. KARL LÜDECKE. Ger. 515,092, Sept. 11, 1928. Salts of choline with negatively substituted aromatic arsonic acids are prepd. by the customary salt-forming methods. The products are cryst. and non-hygroscopic. Examples are given describing the prepn. of the choline salts of, *inter alia*, 4 iodo-3-nitrobenzenearsonic acid, 3,5-dinitro-4-aminobenzenearsonic acid, and 4-carboxybenzenearsonic acid.

Extraction and concentration of vitamins. G. DUBOIS. Belg. 372,102, Aug. 31, 1930. Ground fish ovaries and livers are treated in strong alc. The oily liquid obtained on pressing is sapond. with an alc. alkali soln., and the soap is treated with Me_2CO and Et_2O to obtain vitamin A and with superheated steam to obtain vitamin F.

Medicinal silver preparation. PHYSIOLOGISCH-CHEMISCHES LABORATORIUM HUGO ROSENBERG. Ger. 515,061, Oct. 18, 1927. An ammoniacal soln. of Ag_2O is heated with an excess of starch until the oxide is wholly or partly reduced. An example is given.

Antiseptic solution. THE PEPSODENT CO. Fr. 693,083, Mar. 31, 1930. An antiseptic and disinfectant soln. contains, *e. g.*, chlorothymol 0.1, glycerol 7.5, EtOH 25, AcOH (of 36%) 1 and water 64.4%.

Creams, pomades, etc. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 692,757, Mar. 26, 1930. A protective pomade or cream contains soap 19, gum arabic 4, lanolin 2, glycerol 1 and water 74 parts. Gum arabic may be replaced by dextrin and lanolin by other oily substances.

Perfumes. J. D. RIEDEL-E. DE HAËN A.-G. Ger. 515,332, Dec. 8, 1926. Ethers of 3,4-dihydroxybenzyl alc are used as fixing agents or solvents for perfumes. The prepn. of the dimethyl, methyl ethyl and diethyl ethers is described

Essence d'Orient. JOSEPH JACOBSON. Fr. 693,735, July 22, 1929. Pure Essence d'Orient is obtained by emulsifying the org. materials mixed with it by peralcohol which permits a rapid decantation from the crystals.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Causes of the intoxications produced in the cleaning of sulfuric acid tanks and tank cars. LEYMANN AND WEBER. *Zentr. Gewerbehyg. Unfallverhütung* **17**, 154-9 (1930); *Chimie & industrie* **24**, 832-3(1930).—From a study of a large no. of cases it is concluded that the intoxication is due to AsH_3. Against this were the suppositions that the action of H_2SO_4 on metallic Fe in the presence of reducible As compds. does not produce AsH_3, and that, as com. H_2SO_4 (except contact-process H_2SO_4) contains HNO_3, AsH_3 gas cannot form. Lab. expts. showed that when crude dil. H_2SO_4 acts on Fe in the presence of reducible As compds., AsH_3 can be evolved, even at atm. temp.; at higher temps., even when very dil., H_2SO_4 can still give rise to evolution of AsH_3 under similar conditions; finally, the small quantities of HNO_3 present in technical H_2SO_4 do not prevent the reaction. When cleaning out the tanks or cars, the H_2SO_4 which sats. the sludge heats up on being dild., attacks the Fe and ultimately causes evolution of AsH_3. To prevent the intoxications, cleaning outlets should be provided in the bottom of the tanks, or the washing should be carried out with a large amt. of water, which is continuously siphoned off.

A. PAPINEAU-COUTURE

Lime in 1929. A. T. COONS. Bur. Mines, *Mineral Resources of the U. S.* 1929, Pt. II, 267–98 (preprint No. 20 published January 14, 1931). E. H.

Density of sulfuric acid solutions of copper sulfate. G. CHAPAS, C. CHARMETANT AND A. RAME. *Chimie & industrie* **24**, 794–6(1930).—Control of the manuf. of $CuSO_4$.-$5H_2O$ requires frequent detns. of the compn. of the solns. to maintain the acidity within relatively narrow limits. As the detn. of acidity is relatively long to carry out, curves of the compns. of solns. at different ds. were detd. and plotted on triangular coördinates, the sides of the triangle representing CuO, SO_3 and H_2O, resp., and from them the crystn. curve was obtained. By anamorphosis the crystn. curve was transposed to rectangular coördinates. The diagrams permit obtaining the compn. of H_2SO_4-$CuSO_4$ solns. from the ds. and CuO contents. For the curves and method of using them, the original article should be consulted. A. PAPINEAU-COUTURE

The sulfates in industry—a review of the water-soluble products. IV. Magnesium sulfate. V. Iron sulfates. VI. Zinc sulfate. VII. Copper sulfate. CHAS. H. BUTCHER. *Chem. Trade J.* **88**, 125–6(1931); cf *C. A.* **25**, 1337. —An outline of characteristics required of these sulfates in the industries. W. H. BOYNTON

The problem of the drying of salt. B. LAGRANGE. *Chimie & industrie* **24**, 805–8(1930). —A brief discussion is given of various types of app. for drying salt from a moisture content of 5–8% down to 0.5%, together with approx. figures on the cost of the drying. A. PAPINEAU-COUTURE

Studies on fundamental synthesis of calcium aluminates and their hydration. VII. SHOICHIRO NAGAI AND RYUICHI NAITO. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding, 315–8(1930); cf. *C. A.* **24**, 4370.—Tests show that gehlenite ($2CaO.Al_2O_3.SiO_2$) can be obtained by heating appropriate mixts. of CaO, Al_2O_3 and SiO_2 above 1550° or for a longer time at 1450°. In eutectic mixts. between Ca aluminate and Ca silicate, the combination of CaO and Al_2O_3 or SiO_2 is completed instantly by heating at a little higher temp. than 1300°. Compression tests on the synthesized products of alite and gehlenite and of eutectic mixts. show that the alite has a small value at short curing times, but the strength increases gradually on longer curing in water. The gehlenite has no perceivable strength, but its strength increases remarkably when 5–10% of CaO is added. H. C. PARISH

Anhydrous aluminum chloride: its uses and manufacture. C. SIMON. *Chimie & industrie* **24**, 1317–24(1930).—A brief review is given of the more important uses of $AlCl_3$ with an outline of the chief processes of manuf., more particularly a comparison of the MacAfee and Hagglund processes A. A study on agar-agar. II. TETSUNOSUKE YANAGAWA AND Y. NISHIDA. *Repts. Imp. Ind. Research Inst., Osaka, Japan* 11, No. 14(1930); cf. *C. A.* 23, 4538.—Constituents of *Gelidium amansii* Lamx. and the phys. properties of agar-agar are given. F. I. NAKAMURA

Study of the conditions of cooking of gum tragacanth. A. F. LOMANOVITCH AND VENETZKAIA. *Izv. Tekstiln. Promychl.* 9, No. 3, 71–3(1930); *Chimie & industrie* 24, 947(1930).—From a study of the various factors involved, the following procedure is recommended: swell the finely divided gum in 30 parts of water at 50° for 12–15 hrs. with continuous stirring, heat for 2 hrs. in an open kettle and cool with stirring for 6–8 hrs., at which point max. viscosity is attained. A. PAPINEAU-COUTURE

The production of superphosphate from Khibinsk apatite (VOL'FKOVICH, *et al.*) 15.

British Plastics Year Book, 1931. London: The British Plastics Moulding Trade Assocn. 229 pp.

Hydrocyanic acid. IMPERIAL CHEMICAL INDUSTRIES, LTD., T. S. WHEELER, J. MCAULAY, W. B. FLETCHER and H. A. T. MILLS. Brit. 335,585, March 27, 1929. Fr. 692,542, March 21, 1930. Reaction between a hydrocarbon gas (such as CH_4, C_2H_6, and various natural and artificial industrial gases contg. hydrocarbons) and NH_3, to produce HCN and H is effected by passing a mixt. of the hydrocarbon material with more than one mol. proportion of NH_3 for each at. proportion of C, at a temp. of at least 1150°, rapidly through an unpacked reaction chamber. H or water vapor may be present, the gas mixt. may be preheated to 900° or higher, and the reaction chamber is preferably formed with smooth internal surfaces such as glazed silica or sillimanite. S compds. and CO_2 may be removed from the gases by passing them through aq. or liquid NH_3.

Hydrocyanic acid. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 692,543, March 21, 1930. HCN is produced as described in the preceding patent, but the NH_3 is not used in excess. Instead an appreciable amt. of a diluent such as H or N is used. The hydrocarbon may be coke-furnace gas, and it may be purified and at the same time mixed with NH_3 by bringing it into contact with liquid NH_3.

Phosphoric anhydride. ÉVENCE COPPÉE. Belg. 372,292, Aug. 31, 1930. Phosphates, to which may have been added a substance capable of reducing the reaction temp., *e. g.*, Al_2O_3, are heated in presence of SiO_2.

Phosphoric acid. H. LAWARRÉE. Belg. 370,074, June 30, 1930. Pb oxychloride or hydroxide is used in a closed cycle to isolate phosphoric acid as Pb phosphate in a salt soln. contg. phosphoric acid.

Phosphoric acid; hydrogen. BAYERISCHE STICKSTOFFWERKE A.-G. (Vladimir N. Ipat'ev, inventor). Ger. 514,173, Mar. 1, 1929. See Fr. 670,338 (*C. A.* 24, 1941).

Phosphoric acid and aluminum compounds. I. G. FARBENIND. A.-G. Fr. 693,818, Apr. 12, 1930. Al is pptd. as $AlCl_3$ by HCl gas from a hydrochloric acid soln. of substances contg. Al and H_3PO_4, and the H_3PO_4 is recovered after elimination of the Al. An example is given of the treatment of natural Al phosphate.

Silicic acid. RICHARD WILLSTÄTTER, KARL LOBINGER and HEINRICH KRAUT. Ger. 514,414, Nov. 3, 1928. Stable solns. contg. silicic acid as simple mols. are prepd. by decompg. an alkali silicate soln. with an acid, or by the reaction of a silicon halide with an aq. suspension of Ag_2O or other suitable base, and acidifying the soln. so obtained until the hydrion concn. lies between p_H 1.5 and 3.5. Examples are given.

Apparatus for effecting gas reactions such as catalytic production of sulfuric acid, ammonia or methanol. LUIGI CASALE. U. S. 1,790,853, Feb. 3. Various details are described of an app. with baffle plates and partitions arranged for heat-exchange between products of reaction and gases supplied for the reaction.

Removing arsenic from acids. METALLGES. A.-G. Fr. 692,595, Mar. 24, 1930. As is removed from a concd. acid such as H_2SO_4 of 60° Bé. by the addn. of the exact amt. of H_2S necessary to convert the As to sulfide.

Purifying acids or acid salts. PAUL BOESSNECK. Ger. 514,499, Sept. 26, 1929. Solns. of acids or acid salts obtained by treating solns. of Ca salts with H_2SO_4 are freed from dissolved $CaSO_4$ by addn. of HF.

Salts of cyanic acid. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Fr. 692,481, Mar. 21, 1930. Salts of cyanic acid are prepd. by heating, in the absence of solvents, urea with alk. earth compds. such as CaO, $Ca(OH)_2$, CaC_2 or alkali compds. such as Na_2CO_3 or K_2CO_3.

Synthesis of ammonia in presence of inert gases. AMMONIAQUE SYNTHÉTIQUE ET DÉRIVÉS, SOC. ANON. Belg. 372,057, Aug. 31, 1930. After having been freed from NH_3, the gases are partly returned to the same tower along with the gas from the preceding tower (or the fresh gas in the case of the 1st tower), and partly sent to the next tower (or the gas discharge in the case of the last tower).

Synthesis of ammonia. SOC. CHIM. DE LA GRANDE PAROISSE (AZOTE ET PRODUITS CHIM.). Fr. 693,712, July 9, 1929. Small quantities of CO_2 in the gases for the synthesis of NH_3 are removed by the action of the CO_2, NH_3 and steam to form $(NH_4)_2CO_3$, sufficient steam being left in the gas, so that during the final condensation it carries down the $(NH_4)_2CO_3$.

Gaseous syntheses. UNIVERSITÄTS-INSTITUT FÜR PHYSIKALISCHE GRUNDLAGEN DER MEDIZIN. Fr. 693,641, Feb. 28, 1930. In gaseous syntheses of surface reaction type by means of elec. discharges, the reaction chamber in which the elec. discharges are passed through the gas is heated to above the critical temp. of the gas to be prepd. Examples mentioned are the *prepn. of* NH_3 and C_2H_2.

Oxidation of ammonia. E. I. DU PONT DE NEMOURS & Co. Fr. 692,824, Mar. 27, 1930. NH_3 is oxidized to oxides of N by passing a mixt. contg. NH_3 and O in contact with a catalyst of the Pt group, the exposed surface of which per unit section of the gaseous current is more than 4 thicknesses of gauze of 23–63 mesh per linear cc., formed of threads of 127–25 thousandths of a mm. in diam

Oxidizing ammonia. E. I. DU PONT DE NEMOURS & Co. Fr. 693,559, April 8, 1930. NH_3 is oxidized to oxides of N by passing a mixt. of NH_3 and O over catalysts and rapidly cooling the reaction mixt. to below 500°. An app. is described.

Oxidizing ammonia with oxygen. FRANS G. LILJENROTH. Ger. 514,392, Sept. 9, 1926. See Swed. 65,260 (*C. A.* **24**, 1473).

Alkali ferrocyanides. HAMBURGER GASWERKE G. M. B. H. Fr. 692,868, Mar. 28, 1930. Alkali ferrocyanides are prepd. during the extn. of HCN from coal gas by washing, by means of bivalent compds. of Fe suspended in an alk. lye contg. an excess of alkali. The excess of alkali depends in amt. and concn. on the content of HCN in the coal gas, so that only sol. ferrocyanides are produced, and this excess after being transformed into carbonate or bicarbonate by the CO_2 in the gas is neutralized.

Alkali chromates. MUTUAL CHEMICAL CO. OF AMERICA. Fr. 692,614, March 24, 1930. See U. S. 1,752,863 (*C. A.* **24**, 2553).

Alkali or alkaline earth salts from the corresponding chlorides. H. LAWARRÉE. Belg. 370,808, July 31, 1930. The acid is brought into contact, in aq. medium, with the chloride in presence of an oxide, hydroxide or basic mercurous or mercuric salt which can combine with the Cl ion. The $HgCl_2$ or Hg_2Cl_2 produced is treated with a base to regenerate the oxide or other mercurous or mercuric salt. Cf. *C. A.* **25**, 779.

Chromium compounds. GINO PANEBIANCO and VIRGINIO A. DE LIBERA. Fr. 692,786, Mar. 26, 1930. Industrially pure Cr compds., particularly a mixt. of Cr_2O_3 and $H_2Cr_2O_4$ or its salts, are obtained from crude materials such as Cr ores or slags, by mixing the crude material with substances contg. pure or combined C and submitting the mixt. to the catalytic action of Cl in the presence of free or combined O.

Alkali metal phosphates. METALLGES. A.-G. Brit. 335,492, Oct. 17, 1929. Phosphates such as Na_3PO_4 and K_3PO_4 are produced by fusing (suitably at a temp. of about 1150–1250°) a mixt. of alkali metal sulfate and a metal-P alloy such as ferro-P, P-Cu or P-Mn (preferably in the form of powder or small lumps) in a elec. resistance furnace. Various details of procedure for avoiding atm. oxidation, etc., are described. The reaction product is leached with water, and metal sulfide is obtained as a by-product.

Phosphates. PHOSPHATE RECOVERY CORP. Fr. 692,731, Mar. 25, 1930. Phosphatic material contg. particles of phosphate and particles of gang is concd. by treatment with alkali and with oil and sepn. by a surface flotation. An app. is described. Cf. *C. A.* **24**, 1473.

Phosphates. SOC. D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIMIQUES (Étienne T. de Boismilon, inventor). Fr. 693,736, July 22, 1929. A Ca phosphate having a content of citrate-sol. P_2O_5 of at least 36% of the dry product is obtained by adding the ground natural phosphate very slowly to the HCl soln. (contg. not more than 70 g. HCl per l.) at a temp. of about 30°.

Phosphotungstates. JOSHUA F. DARLING (to E. I. du Pont de Nemours & Co.).

U. S. 1,790,905, Feb. 3. For purifying phosphotungstates such as Na phosphotungstate in a mother liquor the crude tungstate liquor is acidified (suitably with HCl), an aromatic amine such as dimethylaniline is added, the repptd. phosphotungstate formed is removed, the ppt. is treated with an alk. substance such as NaOH and the amine is steam-distd. off.

Metal carbonyls. I. G. FARBENIND. A.-G. (Leo Schlecht and Emil Keunecke, inventors). Ger. 515,464, Aug. 19, 1928. See Fr. 679,542 (*C. A.* **24**, 3865).

Manufacture of ammonium sulfate from the spent gases of coke ovens and synthetic-ammonia plants. R. LEDENT. Belg. 370,942, July 31, 1930. $FeSO_4$ is used in the neutralizers, instead of H_2SO_4. The pptd. $Fe(OH)_2$ is air-dried and used as Fe ore. The concd. $(NH_4)_2SO_4$ soln. is crystd.

Utilizing dilute sulfuric acid for the manufacture of ammonium sulfate. SOC. GÉNÉRALE DE FOURS À COKE (SYSTÈMES LECOCQ). Fr. 692,789, Mar. 26, 1930. See Belg. 359,553 (*C. A.* **24**, 950).

Aluminum chloride. I. G. FARBENIND. A.-G. (Johannes Brode and Carl Wurster, inventors). Ger. 515,033, June 2, 1929. Anhyd. $AlCl_3$ free from Fe is prepd. by fusing the crude salt with a reducing agent, *e. g.*, Al, and sepg. Fe from the melt by electromagnetic means, *e. g.*, by suspending an electromagnet in the melt.

Magnesium chloride. ELISA LACELL NÉE VANDER-VORD. Fr. 693,232, April 3, 1930. Carnolite or $MgCl_2$ is dehydrated by adding gradually to a relatively large anhyd mass of $MgCl_2$ or $MgCl_2$ and KCl relatively small quantities of the salt to be dehydrated, to cause a rapid evapn. of the water and prevent the formation of oxides.

Potassium nitrate. KALI-FORSCHUNGS-ANSTALT G. M. B. H. Fr. 693,181, April 2, 1930. A mixt. of $Al(NO_3)_3$ and KCl is heated until no more nitrous gases or Cl sep., and the KNO_3 is dissolved in water or in KNO_3 solns. The Al_2O_3 is reconverted to $Al(NO_3)_3$ by HNO_3, the nitrous gases being used as well. Cf. *C. A.* **24**, 3091.

Potash and alumina. FELIX JOURDAN. Fr. 693,074, Mar. 31, 1930. KOH and Al_2O_3 are obtained from leucite by heating limestone with leucite and a suitable flux to the m. p., cooling, grinding and leaching with a soln. of K_2CO_3 to neutralize the CaO and ppt. it as $CaCO_3$.

Selenium sulfide. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 692,758, Mar. 26, 1930. Stable active SeS_2 of definite compn is made by satg. a soln. of $AlCl_3$ with H_2SO_4 and adding a soln. of H_2SeO_3 with continued addn. of H_2SO_4. A yellowish sol is first formed which is converted to a yellow flocculent ppt. A temporary and moderate excess of acid gives a sol The ppt. is washed and dried. $BaCl_2$ may be used instead of $AlCl_3$. Another method consists in mixing S and Se in the theoretical proportions and heating to 225°. The plastic product obtained slowly changes and becomes fragile and hard. The SeS_2 may be combined with a hydrophile medium such as bentonite by heating the 2° to 125–150°. The *product may be used for the vulcanization of rubber* or in aq. suspension as a *fungicide* or *insecticide*.

Sodium cyanide. S. COULIER. Belg. 372,147, Aug. 31, 1930. A mixt. of carbonaceous material, alkali salts and catalyst is treated with hot N, with addn. of a quantity of Na salts equiv. to the quantity of NaCN required. After sepn. of NaCN, the mass is treated with steam under pressure to produce formates and NH_3. Cf. *C. A.* **25**, 385.

Recovery of sodium carbonate from "tails salts." HARRY W. MORSE. U. S. 1,791,281, Feb. 3. "Tails salts" contg. Na_2CO_3, such as those produced from Searles Lake brine, are washed with water at a temp. of 30–40° in order to dissolve out Na_2CO_3.

Sodium chromate; alumina. I. G. FARBENIND. A.-G. (F. Wissing, inventor) Ger. 513,942, Feb. 5, 1930. Addn. to 505,318. In the method of Ger. 505,318 (*C. A.* **24**, 5949), the extn. of the sol. portion is effected by heating the melt with water under pressure to a temp. above 100°, *e. g.*, to 230°. The ext. thus obtained is relatively free from SiO_2.

Sodium fluoride. E. V. BRITZKE, W. I. BREMPELL and M. E. JAKUBOWITZ. Brit. 335,703, Aug. 29, 1929. NaF (neutral, acid or mixed) is obtained by the action of gaseous HF on solid calcined soda at an elevated temp. (suitably 70°), and the acid fluoride formed may be further neutralized with calcined soda. App. is described.

Acid disodium pyrophosphate. METALLGES. A.-G. Brit. 335,501, May 17, 1929. This compd. is obtained by evapg. *in vacuo* (suitably at 180–200°) a soln. contg. H_3PO_4 (which may be that obtained by decompg. crude phosphates with H_2SO_4) and a proper proportion of NaCl.

Bleaching powder. I. G. FARBENIND. A.-G. Ger. 514,390, May 24, 1928. Ground $Ca(OH)_2$ is suspended in an inert liquid, *e. g.*, CCl_4, and treated with Cl at a temp. above

40°, the mixt. being rapidly cooled below 20° when the reaction is completed. The product is dried *in vacuo* at a low temp.

Mixtures of hydrogen and carbon oxides. BRITISH CELANESE, LTD., W. BADER and E. E. STIMSON. Brit. 335,632, July 2, 1929. Mixts. of CO_2 and H such as those obtained by releasing the pressure upon wash waters used in treating industrial CO and H mixts., have their H content reduced or eliminated by treatment with chromite above 700° (preferably at 800–900°), which increases the CO content of the mixt. so that it may be used for CO production by drying and passing it over hot coke or charcoal.

Animal black. BAUGH & SONS CO. Fr. 693,239, April 3, 1930. See Ger. 512,484 (*C. A.* **25**, 1045).

Roasting sulfur ores. SAUREFABRIK SCHWEIZERHALL. Fr. 692,569, Mar. 22, 1930. S ores or other materials contg. S are roasted in mech. furnaces of several floors in countercurrent to air, the ore, etc., passing over intermediate floors to which only part of the air has access to prevent premature cooling by the air.

Condensation products. I. G. FARBENIND. A.-G. Fr. 693,750, April 11, 1930. Condensation products are obtained as a fine powder without odor, by the reaction of aliphatic aldehydes, or their mixts., with bases of the naphthalene series in the presence of acids in alcs. sol. in water, and treatment of the products with water. Examples are given.

Condensation products of urea and formaldehyde. MARTIN LUTHER and CLAUS HEUCK (to I. G. Farbenind. A.-G.). U. S. 1,791,062, Feb. 3. Condensation is effected with an aq. soln. of urea and CH_2O in which a p_H of 4 to 7 is maintained by addn. of buffer compds., and there is added to the condensation product, prior to hardening, a substance such as $MgCl_2$ or formamide which is capable of forming acid in the liquid condensation product during the heat treatment employed for the hardening.

Resitols. AUG. NOWACK A.-G. and RICHARD HESSEN. Fr. 693,004, Mar. 29, 1930. The initial sol. and fusible condensation products (resols) from phenols and CH_2O, if necessary with the addn. of accelerators or the polymers or homologs of, CH_2O, are heated in thin layers for a short time, preferably repeated, until the whole or a greater part of the volatile constituents are eliminated and the resitol formed contains the desired amt. of resol for the final treatment of the resulting resitol.

Cyanamide-formaldehyde condensation products. HANS SCHMIDT (to I. G. Farbenind. A.-G.). U. S. 1,791,433, Feb. 3. Formaldehyde is caused to act on cyanamide in aq. soln. contg. a "strong" inorg. acid such as dil. HCl, while heating (suitably at a temp. of the water bath) until the condensation product seps. in an amorphous condition. U. S. 1,791,434 also relates to effecting reaction between cyanamide and CH_2O, as by heating in dil. alk. aq. soln.

Plastic materials. COMPAGNIE FRANÇAISE D'ACCUMULATEURS ÉLECTRIQUES. Fr. 692,565, Mar. 22, 1930. A plastic material for molding hard elastic products, particularly suitable for molding accumulator vats, contains a mixt. of cotton-oil tar from the residues obtained in purifying cotton oils with H_2SO_4, petroleum tar, fibrous materials and a mineral charge. An example contains cotton-oil tar 40, petroleum tar 20, kieselguhr 30 and asbestos or jute 10%.

Molding casein. ADALBERT ZSIGMONDY. Ger. 515,376, Dec. 4, 1926. See Brit. 298,815 (*C. A.* **23**, 3061).

Composition for use in modeling, sculpture, pottery, etc. KARL F. HÖLLER and STEFAN SCHLESS. Ger. 515,442, Dec. 28, 1928. See Austrian 119,622 (*C. A.* **25**, 784).

Stabilization of dispersions of substances little soluble in water. N. V. BATAAFSCHE PETROLEUM MAATSCHAPPIJ and HYMAN LIMBURG. Dutch 23,111, Dec. 15, 1930. Aq. emulsions or suspensions of water-insol. substances, oils, tar, asphalt, rubber, etc., are stabilized by the addn. of small quantities of sulfonic acids. The latter are derived from petroleum products (lubricating-oil fractions) by repeated sulfonation with 10% oleum (20% SO_3) at 50°. The acid sludge from the 4th or 5th sulfonation is neutralized, and the sulfonic acids are dissolved in water. In a 5% alkali sulfonate soln. 160% of asphalt can be dispersed to a stable emulsion. The active sulfonic acids have a min. mol. wt. of 500, are insol. in xylene and CCl_4, and are not pptd. by $CaCl_2$. Cf. *C. A.* **24**, 444.

Adhesive for belts and the like. A. PLONSKIER. Belg. 369,970, June 30, 1930. The product is a mixt. of lanolin, wax (*e. g.*, paraffin) and fish oil (*e. g.*, cod-liver oil).

Adhesive. WILLIAM B. WESCOTT (to The Rubber Latex Research Corp.). Can. 308,567, Feb. 10, 1931. A plastic adhesive for laminated articles comprises heat-coagulated hemoglobin, rubber and a vulcanizing agent. It is used for securing rubber and rubber compns. to metal, bakelite, wood, etc. Cf. *C. A.* **24**, 2257.

Wetting, etc., agents. H. TH. BÖHME A.-G. Fr. 692,862, Mar. 28, 1930. Wetting

impregnating, dispersing or froth-forming agents contain the reaction products of org. bases on sulfonated higher aliphatic alcs. Thus pyridine or pyridinic bases react with sulfonated lauric or stearic alc.

Wetting, etc., agents. I. G. FARBENIND. A.-G. Fr. 693,620, April 10, 1930. Wetting, cleansing, dispersing and solvent agents are made by treating with H_2SO_4, SO_3 or $ClHSO_3$ carboxylic acids of the aliphatic, cycloaliphatic, aliphatic-aromatic or aromatic series or their NH_2 or substituted NH_2 derivs The reaction materials are so chosen that the products contain at least one double or triple bond or at least one hydroxyl group, and the products or amides of carboxylic acids prepd. in any manner contg. at least one double or triple bond or a hydroxyl group in the mol. Solvents or diluents such as $C_2H_3Cl_3$, CCl_4, ether or $PhNO_2$ may be used. Solvents or diluents such as org. or inorg. acids, anhydrides or chlorides capable of forming mixed anhydrides with sulfonating agents are only used with substances contg. hydroxyl groups which do not possess double or triple bonds. Several examples are given.

Wetting, etc., agents. I. G. FARBENIND. A.-G. Fr. 693,699, April 11, 1930. Wetting, cleansing, dispersing and solvent agents are prepd. by transforming aliphatic, aromatic or aliphatic-aromatic ketones or their derivs. or mixts., obtained during the prepn. of ketones, into true sulfonic acids. Examples are given of the sulfonation of oleone, palmitone, pentadecylnaphthyl ketone and others.

Artificial sponge. I. G. FARBENIND. A.-G. Ger. 512,748, Mar. 24, 1929. Artificial sponge is made from viscose, fibrous material and a filling material consisting wholly, or in part, of acid salts. The porosity of the sponge is obtained by removing the filling material. Thus, viscose is mixed with cotton, flax, etc., and NH_4HSO_4 or $NaHSO_4$, molded and the salt removed. Cf. *C. A.* **25**, 1048.

Kiln for preheating and clinkering of raw materials in powdered form such as lime or cement material. EDOUARD P. C. GIROUARD. U. S. 1,791,165, Feb. 3.

Friction material suitable for clutch and brake facings. I J. NOVAK. Brit. 335,549, May 21, 1929. See U. S. 1,766,932 (*C. A.* **24**, 4365).

Friction material suitable for brake lining, etc. ISADOR J. NOVAK (to Raybestos-Manhattan, Inc.). U. S. 1,790,944, Feb. 3. A potentially reactive but unreacted thin fluid mixt. is prepd. comprising $(CH_2)_6N_4$, cresylic acid and a modifier such as China wood oil. A fibrous base such as asbestos millboard is satd. with this mixt., and the satd. base is heated in a closed container, while preventing substantial loss of vapors, to initiate reaction and partial hardening; the heating is continued until the satd. base assumes marked plasticity, after which the material is cured at a higher temp. to convert the satd. compn. into an insol. infusible state. Cf. *C. A.* **24**, 4365.

Stencil sheet. SHINJIRO HORII. U. S. 1,790,987, Feb. 3. A stencil sheet adapted for stenciling by pressure consists of a base of fibrous material such as Japanese Yoshino paper having a coating comprising esters of polysaccharides such as cellulose nitrate or starch acetate together with dolphin oil, etc. Cf. *C. A.* **24**, 699, 4598; **25**, 567.

Magnetic material in fine dust form suitable for loading coils and other cores. JAMES E. HARRIS (to Bell Telephone Laboratories, Inc.). U. S. 1,790,704, Feb. 3. In order to increase the yield of fine dust from subdividing magnetic material such as Fe, Ni or Co and Mo alloys, the material is melted with a quantity (greater than an incidental impurity and which may amount to several per cent) of Sn, Bi or Pb. Cf. *C. A.* **25**, 786.

Gramophone records. R. H. CHESTER. Brit. 335,660, July 11, 1929. Flexible records such as those with a core of paper, linen or parchment, and covering layers of celluloid or like transparent material have designs or lettering, etc., applied reversely to the transparent material and the latter is then secured adhesively, with the printed surface down, to the core material. Cf. *C. A.* **24**, 5119.

Box-toe material. ALBERT L. CLAPP (to Beckwith Mfg. Co.). U. S. 1,790,796, Feb. 3. A felted material is formed comprising a fibrous pulp such as wood pulp and a relatively longer fibrous material such as long rope or flax fibers, and this is impregnated with a thermoplastic binder such as a rosin, gilsonite and Montan wax mixt. Cf. *C. A.* **24**, 4129.

Composition for filling teeth. C. A. WINTERBAUER and EWALD BREMER. Ger. 515,137, May 7, 1929. The compn. comprises powd. animal teeth, celluloid, and acetone. Powd. Au or Ag may be added.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Glass, its composition and properties. GEO. W. MOREY. *J. Chem. Education* **8**, 421–41(1931).—A review. E. H.

The theory of the composition of glass. E. ZSCHIMMER. *J. Soc. Glass Tech.* **14**, 229–49T(1930).—Graphic methods of representation of the compn. of glass as a quaternary system are discussed. H. F. K.

Effect of alumina and silica on some properties of glass. M. A. BESBORODOV. *Glashütte* **60**, 5–9(1930).—An increase in the Al_2O_3 and SiO_2 contents retarded the devitrification of a B–SiO_2–Al_2O_3–CaO–potash–soda glass, and increased the resistance toward water and Na_2CO_3. The resistance toward NaOH and H_2SO_4 rises with an increase in the SiO_2 content but falls with an increase in that of Al_2O_3. B. C. A.

The influence of manganese oxide on some properties of glass. A. A. CHILDS, VIOLET DIMBLEBY, F. WINKS AND W. E. S. TURNER *Ceramic Industry* **15**, 292(1930).—The replacement of Na_2O by MnO in 3 series of glass batches resulted in lowering the working temp. and the coeff. of thermal expansion; it raised the annealing temp. and improved the chem. stability. M. A. E.

Feldspar, its effect in glass. E. W. KOENIG. *Ceramic Age* **16**, 150–2(1930); *Glass Ind.* **11**, 264–6.—Feldspar in the glass batch is considered from the standpoint of the beneficial effects of alumina. Feldspar causes no mech. or chem. disturbance in the batch, is non-corrosive to tank blocks, and hinders surface sepn. of silica. It should be added at intervals in small quantities to avoid producing glasses of different compns. in the same tank. A bibliography of 19 titles is given. M. A. E.

Plea for uniformity of glass-making materials. R. L. FRINK. *Natl. Glass Budget* **46**, No. 26, 3, 13, 16, 20–1, 24(1930).—F. discusses at length the undesirable effects of variation of Fe content and moisture content, also of the presence of extraneous reducing agents in the raw materials of the batch, sometimes including not only tar and soot, but also catsup, sirups and fruit juices introduced with bottle cullet. Checks and seeds as well as unsatisfactory color, brittleness, and lack of homogeneity in glass may all be traced to such variations in materials. M. A. E.

Effect of various radiations on the coloring of glasses. P. GILARD AND AD. LECRENIER. *Chimie & industrie* **24**, 1035–51(1930); cf. *C. A.* **21**, 3434; **25**, 1049.—A large no. of glasses of known compn. were exposed for several weeks to the light of a Hg-vapor arc. The same and other glasses were exposed to the action of Ra rays for 29 days, and also samples of minerals and of a no. of pure chem. compds. The absorption spectra of the irradiated glasses were measured by the method of G. and Swings (*C. A.* **24**, 5235). From the results G. and L. are inclined to the belief, contrary to Przibram and coworkers, that the action of the Ra rays is like that of the ultra-violet rays in that it affects the mol. rather than the atom. A. PAPINEAU-COUTURE

Note on the influence of different radiations on the coloring of glass. AD. LECRENIER AND P. GILARD. *Rev. universelle mines* **4**, 349–62(1930); cf. *C. A.* **25**, 1049.—The ultra-violet ray has a marked influence on the intimate compn. of glass. It provokes reactions that may modify the aspect of the glass. The fact that certain glass seems unaltered does not mean, necessarily, a lack of internal reactions; the existence of these can be established only through sensible phenomena, such as colorations. In glass containing Cr or other elements existing in several states of oxidation, the action of the ultra-violet ray is clearly shown by displacement of color. The color obtained varies essentially with the compn. of the glass. Because of the lack of permeability of glass to ultra-violet rays, the color is at first superficial and only with time reaches the deep layers and the center of the mass. The color obtained disappears under the action of heat near the softening temp. of the glass. The heat causes reactions that are the reverse of those produced by the ultra-violet ray and destroys the mol. structure the latter has established. The ultra-violet ray acts only chemically and modifies only the mol. structures of bodies. The Ra ray causes deeper disintegrations and attacks the atoms; however, it is possible that under the action of Ra rays there is produced a modification in the relative positions of atoms in the mol. Tests with Ra rays have shown that all glass contg. K_2O gives yellowish green shades while that contg. Na gives shades of brown, the coloring varying with the compn. of the glass, often near the softening temp. Glasses contg. Cu and Fe scarcely seem to be affected by the Ra ray. Ni and Co glasses, on the contrary, are changed in a very perceptible manner. C. W. OWINGS

The making of mirrors by the deposition of metal on glass. ANON. *Bur. Standards Circ.* No. 389, 17 pp.(1931).—This publication supersedes Letter Circ. No. 32 and deals principally with the methods for producing mirrors by the chem. decompn. of Ag on glass. The Brashear, Rochelle salt, and formaldehyde formulas are given, also a detailed discussion of the precautions necessary to avoid danger, and the technic necessary to obtain the most satisfactory results. Reflecting films are produced on glass by the chem. decompn. of Cu, Pt or PbS, by cathode sputtering and by condensation of vaporized metals. W. H. BOYNTON

Preparation of mirrors by sputtering metals on to glass surfaces. A. C. G. BEACH. *J. Sci. Instruments* **7**, 193–5(1930).—Exptl. details are given for the prepn. of mirrors of Ag and Ni by sputtering. B. C. A.

Specifications for tank blocks. W. J. REES. *J. Soc. Glass Tech.* **14**, 124–30P (1930). See *C. A.* **25**, 1051. H. F. K

The corrosion of tank blocks by opal glasses. C. J. UHRMANN AND S. M. SLATER. *J. Am. Ceram. Soc.* **13**, 931–4(1930).—More opacifier must be used in batches for day tanks than for closed pots. The glass used was: SiO_2 65, B_2O_3 1.5, Al_2O_3 5.5, CaO 11.5, K_2O 6.5 and Na_2O 10.0%. During a tank failure a fluid of lower viscosity ran out before the glass came through. A similar vitreous substance was found between the glass and the bottom block. Apparently certain of the corrosive ingredients melt out first and percolate through the batch to the bottom. Cooling the blocks and filling in 3 sep. charges decreased block stones and increased tank life. C. H. KERR

Mechanical handling of raw and manufactured material under the conditions obtained in glass works. T. E. DIMBLEBY. *J Soc. Glass Tech.* **14**, 263-75T(1930). H. F. K.

Some experiments on the cascade method of melting glass. T. C. MOORSHEAD AND E. A. COAD-PRYOR. *J. Soc. Glass Tech.* **14**, 249–60T(1930). H. F. K.

Efficiency of tank furnaces for glass melting. Proposals for the standardization of its nomenclature and methods for its measurement. W. FRIEDMANN. *J Soc. Glass Tech.* **14**, 91–102P(1930). H. F. K

Notes on the effect of load on the fuel consumption of a glass tank furnace. E. A. COAD-PRYOR. *J. Soc Glass Tech.* **14**, 88–90P(1930).—For each 10% increase in the load over a range of 10–100% the increase in the fuel consumption was about 1.9%. H. F. K.

Effect of factory organization and size of pots on the production from pot furnaces. W. W. WARREN. *J. Soc. Glass Tech.* **14** 103–6P(1930). H. F. K.

Manufacture of working life of glasshouse pots. O. BARTSCH. *J. Soc. Glass Tech.* **14**, 107–18P(1930).—A comparison of pots contg the siliceous clays like the Grossalmerode clay and those of higher Al_2O_3 content like the Rakonitz clay showed the siliceous bodies to have higher expansion up to 800°, lower contraction after 1400°, less resistance to thermal shock at temps. below 600°, a higher softening temp. but a lower temp. of complete collapse, and a lower resistance to glass corrosion, though the glass produced was of better quality than that in the more aluminous pots. H. F. K.

Manufacture of glasshouse pots in England. G. V. EVERS. *J Soc. Glass Tech* **14**, 119–23P(1930).—Very good results are obtained with the Old Mine Stourbridge fireclay which contains up to 72% SiO_2 (ignited basis) and about 25% grog of the same material. H. F. K.

Contribution of technical education to ceramic progress. EDWARD ORTON, JR *Trans Ceram. Soc.* 29, 415–36(1930). H. F. K.

Color changes in pastes. G. MILANI *Corriere ceram.* **11**, 453–7(1930).—The color changes are generally due to Fe, Ti, and V. Under oxidizing conditions the color caused by the Fe may vary from yellow to brown, depending on the amount of Ca present. S in the fuel reduces the decoloring power of the Ca; the S combines with the Ca with the formation of white and yellowish colored spots. Sol. salts tend to conc. on the surface during drying, where they cause stains of insol. sulfates by taking up the S from the gases of combustion R. D. BUMBACHER

Shaft furnaces for calcining clays and silica. ALBERT HIRT. *Ceramique* **33**, 272–80(1930). A. J. MONACK

Thermal expansion of silica bricks. BERNARD LONG. *Ceramique* **33**, 268–72 (1930).—The results are expressed graphically. A. J. MONACK

The influence of atmosphere on the load-bearing capacities of fire bricks. S. C. H SWALLOW. *Refractories J.* 6, 85–94(1930).—Load tests were made on specimens from 5 types of fire bricks. All samples showed increased deformation rates in a reducing atm. The effect was greatest on samples with a high Fe content. A change from re-

ducing back to oxidizing conditions restored the original rate of deformation. The effect of steam was negligible. M. A. EDDY

Comparative effects of glass batch, cullet, soda and sulfate on fireclay bricks. P. P. BUDNIKOV. *Feuerfest* **5**, 181–3(1929).—Ten bricks of Russian manuf. of the type used for the bottom and sides of glass tanks were studied. The chem. compn., the refractoriness under load, and the porosity were detd.; the chem. resistance was studied on small cubes in which circular cavities had been bored. The cavities were filled with the reagents, and the specimens were then heated in an elec. furnace and held at 1430° for 2 hrs. The glass-batch mixt. was slightly more active than the cullet, but in neither case was corrosion very marked. The sulfate showed the most corrosive action, especially in the presence of C, since the Na_2S formed reacted vigorously with the refractory material. Soda also proved a powerful corrosive. In every case the degree of corrosion was dependent on the porosity of the material. B. C. A.

Progress in klinker (brick) construction in South Germany. A. LANG. *Ziegelwelt* **61**, 511–4(1930). H. F. K.

German klinker. W. ANGUS MCINTYRE. *Trans. Ceram. Soc.* **29**, 472–6(1930).—German plant processes in the manuf. of "Klinker" are described. The term covers a no. of hard-burned, all-clay bricks, with a variety of colors, produced by maintaining alternately oxidizing and reducing atms. in the kiln. H. F. K.

Factors in the manufacture of porcelain. MARC LARCHEVÊQUE. *Ceramique* **33**, 221–4(1930). A. J. MONACK

Manufacture of roof tile. MILDE. *Ziegelwelt* **61**, 545–8(1930). H. F. K.

Roof tile continuous drier with a horizontal alternating draft. E. GROSZKINSKY. *Ziegelwelt* **61**, 560–1(1930). H. F. K.

Artificial kaolin. JAROSLAV MILBAUER. *Chem Obzor* **5**, 236(1930).—From chem. analysis, checked by x-ray spectrographic tests, the so-called "artificial kaolin" was found to be a waste from the chem. treatment of bauxites by alk. process. It contains only 20% SiO_2 and is apparently an amorphous mixt. of $Al(OH)_3$ and SiO_2. J. K.

Influence of high temperature on Prosyanaya kaolin. V. V. YURGANOV AND M. V. ZUSMANOVICH. *Trans. Ceramic Research Inst.* (Moscow) **1929**, No. 21, 28–55(in German 56–7).—At a burning temp. of 880° reagents cause no changes in kaolin differing from those caused in similar materials. At this temp. kaolinic acid anhydride (metakaolin) apparently exists. At 980° kaolinite decomposes into free SiO_2 and the difficultly sol. form of clay and shows the first sign of formation of one or more Al silicates. At 1050–1100° there is little change except further combination of free SiO_2 and Al_2O_3. No sillimanite was found. At 1200° the difficultly sol. residue increases: it has the compn. $5Al_2O_3.4SiO_2$. At 1320° the ratio is $Al_2O_3:SiO_2 = 2.70:2$, or $4Al_2O_3.3SiO_2$. Kaolin burned at 1400° shows some crystals when examd. in thin layers, increasing at 1470°. At 1400° and above, $Al_2O_3:SiO_2 = 3:2$ (approx.). E. M. SYMMES

Ceramic investigations of Tshasoff-Jar clays. K. KÖHLER. *Trans. Ceramic Research Inst.* (Moscow) **1929**, No. 20, 88–150(in German 187–92).—Great care was taken to obtain a representative sample from agitated slime. Improper expulsion of free and combined water is discussed, and examples and tables are given. Plasticity is detd. by a method based on the Brongiart principle. Tensile strength is shown in tables. Bonding value is detd. by a special app. Clays are grouped according to rate of drying. Total shrinkage was detd. at 400–1410° and plotted in curves. Porosity was detd. on samples burned at the above temps. and shown in curves. The character of porosity was detd. by microstructure, sp. gr. and wt. *vs.* vol. Up to 900° the samples have the same porosity as before burning; above 900° secondary pores form, increasing in no. and size with temp. rise. At 900° there are mainly open pores, but above this temp. there is sintering. At 1200° the clay is completely sintered, the secondary pores closing. Above this temp. the gas trapped in the pores enlarges them. Refractoriness was detd. by comparison with Seger cones. A rational classification of clays is proposed. E. M. SYMMES

Use in the ceramic industry of the sandy Tshasoff-Jar clay called "Balyki." P. N. KAVOKIN. *Trans. Ceramic Research Inst.* (Moscow) **1929**, No. 20, 172–81(in German 194–5).—"Balyki" is a sandy clay, removed as overburden and discarded hitherto. Two samples fired at 1250° showed a total shrinkage of 7–10%, water absorption 1.12%, porosity up to 2.3%. Such clays can be used to make stoneware. About 60–65% of fireclay can be added to them, then fired at 1200° to make fire brick having 4% total shrinkage. Repeated firing causes no after-shrinkage. Resistance to abrupt temp. change is satisfactory. Water absorption is only 5%, and tensile strength 400–500 kg./sq. cm. A table shows deformation under load. Such bricks will not withstand furnace temp. above 1200°. E. M. SYMMES

Feldspar. I. J. FAIRCHILD, GEORGE K. BURGESS AND R. P. LAMONT. *Bur. Standards Commercial Standard C S* 23–30, 18 pp.(1930).—Classification is based on particle size and chem. compn. Chem. classification is in 3 groups: (1) includes ceramic grades based on percentage of SiO_2 and alkali ratio, and contg. less than 4% Na_2O; (2) includes spars used for glazing, based on percentage of Na_2O, and contg. 4% or more Na_2O; (3) includes spars used for glass making, based on SiO_2, Al_2O_3 and Fe contents. Tables are given with grades and specifications. Standard methods of phys. and chem. tests are given in detail. Chem. methods include analysis for SiO_2, "R_2O_3," Al_2O_3, Fe_2O_3, CaO, MgO, K_2O, Na_2O and ignition loss. Acceptors of this standard are listed. The effective date for production under this classification is Sept. 1, 1930.
ALICE W. EPPERSON

Ceramic bodies described according to their mineral compositions and as silicates. JOSEF WOLF. *Sprechsaal* 63, 929–31(1930).—A supplement to similar work by W. appearing in *C. A.* 22, 852. C. H. LORIG

Refractory materials for electric furnaces. I. The melting of lead and its alloys. ALFRED B. SEARLE. *Metal. Ind.* (London) 38, 3–4(1931).—The max. temp. attained in an elec. furnace when melting Pb or Pb alloys is about 1000°, and generally much lower. Elec. furnaces are the most suitable for melting this class of alloys. The properties of various refractory bricks are outlined. Magnesia brick is suitable for parts of a Pb furnace in contact with slag. For most induction furnaces dead-burned magnesia is best with pitch or colloidal MgO as binding material. A melted mixt. of PbO and clay applied as a paste affords protection to the refractories in high-frequency furnaces for these fusible alloys. Silica bricks are used in the roofs. Most refractory materials are good conductors of electricity at red heat; this often results in serious leakage of current and may cause a serious defect in the furnace. W. H. BOYNTON

The vitreous enameling of cast iron. J. H. D. BRADSHAW. *Foundry Trade J.* 44, 123–4, 129(1931); cf. *C. A.* 24, 2261.—A review. E. H.

The microscopic structure investigation in service in the enamel technic. FRITZ KRAZE AND VIKTOR LINDT. *Sprechsaal* 64, 1–4(1931).—Metallographic methods show defects appearing between the ground coat, cover coat and the iron. C. H. L.

Use of nepheline for enamels. A. I. ZHILIN. *Keram. i Steklo* 6, 485–8(1930).—Tests showed that nepheline from the Ural mountains can be used with success instead of feldspar in ground or white enamels. M. V. KONDOIDY

The effect of furnace gases on the quality of enamels for sheet steel. ANDREW I. ANDREWS AND EMANUEL A. HERTZELL. Univ. Ill. Eng. Expt. Sta., *Bull.* No. 214, 29 pp.(1930); cf. *C. A.* 24, 5957.—Small quantities of SO_2 such as are sometimes found in the atm. of industrial districts may be deleterious in enamel baking through its etching or pock-marking action. H. L. OLIN

Ashes and the remains of fuel found by the excavation of ruins of a seventeenth century glass factory near the Keizergracht at Amsterdam(KREULEN) 2.

Taschenbuch für Keramiker, 1931. Band I. Textband. FRITZ H. ZSCHACKE: **Glas.** H. J. KARMAUS: **Email.** 248 pp. **Band II. Alph. Führer durch der Keramik, Glas- und Emailindustrie mit Bezugsquellen.** 178 pp. Berlin: Verlag Keramische Rundschau. Linen, M. 4

Glass making. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIM. DE SAINT-GOBAIN, CHAUNY & CIREY. Fr. 692,932, June 28, 1929. Means for controlling the temp. of app. used for rolling glass.

Apparatus for feeding mold charges of molten glass. EVERETT S. GREER (to Hazel-Atlas Glass Co.). U. S. 1,790,984, Feb. 3. Structural features.

Glass tank. KARL G. KUTCHKA. U. S. 1,790,820, Feb. 3.

Anchoring device for use in drawing sheet glass. ARTHUR E. SPINASSE. U. S 1,790,774, Feb. 3. Structural features.

Apparatus for making sheets of glass. MISSISSIPPI GLASS CO. Fr. 693,889, April 14, 1930.

Apparatus for rolling glass. CLAUDE LOCREILLE. Fr. 692,500, Mar. 21,1930.

Apparatus for annealing glass. SOC. ANON. DES MANUFACTURES DES GLACES ET PRODUITS CHIM. DE SAINT-GOBAIN, CHAUNY & CIREY. Fr. 692,971, July 5, 1929.

Treating frosted glass articles. ROWLAND D. SMITH (to Corning Glass Works). U. S. 1,791,066, Feb. 3. Articles such as lamp bulbs are washed in an aq. soln. of a simple Al salt of an aliphatic org. acid such as Al tartrate in order to prevent or lessen weakening. Cf. *C. A.* 24, 5124.

Wire glass production. GEORGE AURIEN (to Mississippi Glass Co.). U. S. 1,791,260, Feb. 3. Mech. features.

Apparatus for treating sheets of reënforced glass. DUPLATE CORP. Fr. 693,395, April 5, 1930.

Laminated glass. JAMES F. WALSH and JOHN H. STEVENS (to Celluloid Corp.). Can. 308,522, Feb. 10. 1931. Sheets of glass have interposed therein a pyroxylin sheet contg. cellulose nitrate having a N content of 10.5–11.5%, 35–50 parts of camphor to 100 parts of cellulose nitrate, urea, a residual solvent comprising volatile alc., and a coloring matter opposed to yellowness.

Safety glass. (MISS) M. SCHMIDT. Belg 371,936, Aug. 31, 1930. One or more sheets of cellulosic material are placed between two or more sheets of glass, without interposition of adhesive. The combined sheets are immersed into one or more baths which transform the surface of the cellulosic material into a film which can adhere to glass. The baths are composed of glycol monochlorohydrin, BuOAc, etc.

"Splinterless" glass sheets. JOHN JEFFRAY. Fr. 693,127, April 1, 1930. See Brit. 327,949(*C. A.* **24**, 5124).

Mixing clay and chamotte. W. LOTHES NACHFOLGER MAX STEPHAN. Ger. 515,171, Jan. 18, 1925. The chamotte is sprayed with water in a screw conveyor which delivers it to a wet mixer. The clay is fed to the mixer by another conveyor.

Bricks. ALFRED PAUL, JR. U. S. 1,791,372, Feb. 3. A highly porous light material such as volcanic ash is broken into small particles and 85–90% of this material is mixed with 15–10% of unslaked lime and water is added and the materials are agitated together in a closed space in which the steam generated is retained under pressure; the material is molded into bricks and the latter are subjected to the action of steam under pressure.

Piling brick for burning. ARTHUR J. THERRIEN (to National Brick Co). U. S 1,790,882, Feb. 3. Mech. and structural features.

Tile and similar products. DAVIS A. CABLE (to U. S. Quarry Tile Co.). U. S. 1,791,234, Feb. 3. A block of moist material is dried to beyond the plastic limit, trued and then burned. An arrangement of app. is described.

Ceramic vessels. MAX HAUSER. U. S. 1,790,918, Feb 3. Ceramic vessels of good toughness and heat cond. are made by shaping and firing a mixt. of a ceramic raw material and a Cr alloy such as ferro-Cr and Si.

Decorating ceramic objects. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Fr. 692,562, Mar. 22, 1930. Ceramic objects are decorated with Au, to which Ag, Cu or Bi may be added, the baking of the powder being effected in the presence of metals capable of increasing the resistance of the Au to the fire, such as Rh, Cr, U and like metals. Cf. *C. A.* **24**, 215.

Decorating pottery. DEUTSCHE GOLD- UND SILBER SCHEIDEANSTALT VORM. ROESSLER. Brit. 335,788, Nov. 9, 1928. The process of decorating described in Brit. 308,226 (*C. A.* **24**, 215) is modified by the use of ceramic enamel colors, and thus veins of a darker shade than the groundwork, or of variegated shades, can be produced. Various details and formulas of coloring compns. are given. Brit. 335,789 relates to the use of similar processes for coloring *metal* surfaces such as Al.

Apparatus for the continuous baking of ceramic products. FOURMENT ET LADURÉE (S. A. R. L.). Fr. 692,643, June 22, 1929.

Abrasive. BAKELITE CORP. Fr. 692,733, Mar. 25, 1930. An abrasive is made by mixing abrasive grains, a finely divided substance and a resinoid capable of being hardened. The mixt. is molded and heated until the resinoid hardens. Cf. *C. A.* **24**, 2569.

Abrasives. NORTON CO. Fr. 692,738, Mar. 25, 1930. An abrasive consists of a cryst. α-alumina free from non-aluminous impurities and β-alumina. Cf. *C. A.* **24**, 2854.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Studies on calcium ferrites and iron cements. IV. SHOICHIRO NAGAI AND KATSUHIKO ASAOKA. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding, 256–7(1930); cf. *C. A.* **24**, 4605.—Analyses of mixts. of the 3-component system, SiO_2–Fe_2O_3–CaO, after heating at increasing temps. showed that Ca ferrite formed first, and later SiO_2 and CaO combined to $CaO \cdot SiO_2$ and then to $2CaO \cdot SiO_2$ and $3CaO \cdot SiO_2$. V. *Ibid* 312–5.—The combination in Fe cements is hardly completed at 1450–1500°, which is higher than the sintering temps. of ordinary portland cement mixts. and nearly 100–

150° higher than those of Kuehlzement raw mixt. Compression tests on the synthetic mixts. used in these expts. show somewhat smaller strengths than those of ordinary and special portland cements owing to the large contents of $2CaO \cdot Fe_2O_3$ and small contents of $3CaO \cdot SiO_2$. H. G. PARISH

Examination of road material with small samples. R. GRENGG. *Mikrochemie* [N. S.], **2**, 281–92(1930).—At the Technische Hochschule at Vienna it has sometimes been desirable to test small samples of materials used in road construction or of the pavement itself. In this paper some interesting information is given concerning grain size after pulverizing, and 2 instruments are shown: a ram for prepg. and testing small samples and a machine for testing small samples under pressure and under bending strain. W. T. H.

Report of Committee XVII on wood preservation. F. C. SHEPHERD, *et al.* *Proc Am. Ry. Eng. Assoc.* 1930, 659–770.—*Revision of manual.*—Tables prepd. by the Bureau of Standards for correcting the vol. and sp. gr. of creosote oils for different temps. are presented for adoption as standard. *Definitions* used in wood preservation: A final revision of the list of important terms in the industry is presented. *Service records.*—Data of completed service tests of ties, supplementing previous tables, are given; the annual table for tie renewals has been extended to include 27 railroads to 1928; reports on special test tracks on 7 large trunk lines are submitted. *Piling for marine construction.*—Progress reports of exposure tests of treated and untreated wood specimens for resistance against marine borers are submitted. *Creosote-petroleum treatments.*—Inspection of creosote-petroleum and zinc-petroleum ties on the Atchison, Topeka and Santa Fé R. R. is reported. *Termite destruction.*—An extensive report is given, with comprehensive bibliography, on termite injury to wood in railway structures and on methods of prevention. *Loss of preservative in treated ties due to oil-burning weed destroyers.*—Preliminary tests indicate very small loss from ordinary operation of such machines; no final conclusions are drawn. ALFRED L. KAMMERER

Report on work on protection of timber during the year 1929-30. GEORGE BARGER. Dept. Sci. Ind. Research, *11th (interim) Rept. Comm. Inst. Civil Eng.* Deterioration of Structures in Sea Water, 1930, 13–5; cf. *C. A.* **24**, 3876.—Several of the tests of treated timbers exposed to marine-borer attack at Colombo and Singapore have been completed, the remainder being still under observation. The conclusions to date are: Creosote to which D. M. (chlorodihydrophenarsazine) has been added shows no advantage over creosote alone; with the EtOH solns. of 4 arsenical compds. 2% (and in most cases 0.6%) of D. M. gives protection in the treated portions of the wood; with less active poisons and lower D. M. concns. there is serious attack; fuel oil as a vehicle yields unsatisfactory penetration; Pintsch gas tar gives excellent penetration and is suggested as a vehicle for toxics. ALFRED L. KAMMERER

Impregnation of the ninth series of timber test pieces for exposure at Kilindini and Mauritius and experiments on the impregnation of incised timber. S. M. DIXON. Dept. Sci. Ind. Research, *11th (interim) Rept. Comm. Inst. Civil Eng.* Deterioration of Structures in Sea Water, 1930, 16–8; cf. *C. A.* **24**, 3876.—Swedish fir blocks were treated with naphthalene alone and in various combinations with creosote by the Bethell process and exposed to borer attack at Kilindini and Mauritius. Tests with incising Oregon fir timbers to a depth of $^3/_4$ in. in staggered rows 1.5 in. apart center to center showed a very considerable increase in penetration of creosote with little reduction in strength. ALFRED L. KAMMERER

Termites and termite damage with preliminary recommendations for prevention and control. S. F. LIGHT, MERLE RANDALL AND FRANK G. WHITE. Calif Agr. Expt. Sta., *Circ.* **318**, 3–64(1930).—Coal-tar creosote or $ZnCl_2$ used thoroughly to impregnate wood will protect lumber, posts, ties, etc., effectively against termites. Cyanide fumigation is not a satisfactory control measure. *o*-Dichlorobenzene is fairly effective and does not constitute a fire hazard When a 10% soln. of Na_2HAsO_3 is liberally used on soil or in masonry foundations, termites are effectively controlled. A nontoxic ground treatment consists of a 10% soln. of $CuSO_4$ or $ZnCl_2$. C. R. FELLERS

Determination of Mg in portland cement (REDMOND, BRIGHT) **7.** Natural weathering and a comparison of chemical and natural weathering of building stones (KAISER) **8.** Improved asphalt extractor (STANTON) **22.** Kiln for preheating and clinkering of cement material (U S. pat. 1,791,165) **18.** Preserving wood, glue, etc. (Brit. pat. 335,527) **15.**

Cement and Concrete; A General Reference Book. Chicago: Portland Cement Assocn. 64 pp.

KNUCHEL, HERMANN: **Untersuchungen über den Einfluss der Fällzeit auf die Eigenschaften des Fichten- und Tannenholzes. Tl. I. Der Einfluss der Fällzeit auf einige physik. und gewerbl. Eigenschaften der Holzes.** Bern: Büchler. 127 pp. F. 5.

Cement. ARTHUR ANKER. Fr. 693,552, April 8, 1930. The crude materials used for making cement by heating to the commencement of fusion are stored for a certain time, with or without exposure to steam, in ripening silos heated or insulated from the cold.

Portland cement. THE ASSOCIATED PORTLAND CEMENT MANUFACTURERS, LTD. Fr. 693,206, Apr. 2, 1930. A white portland cement is obtained from colored raw materials by treating the cement during or immediately after the calcination and before the cement has cooled, with a reducing agent, after which the cement is rapidly cooled to a temp. preventing fresh oxidation. The reduction may be carried out by projecting finely divided coal on to the cement as it leaves the furnace or by emptying the red hot cement on to a surface covered with a film of paraffin.

Manufacture of artificial portland cement and similar products. R. POURBAIX. Belg. 371,579, Aug. 31, 1930. The paste or slurry to be burned is introduced at or near the top of the stack through which the gases from the kiln are discharged, so as to recover the heat of the gases and prep. the paste for the burning. Grates or perforated plates are provided in the stack to distribute the material uniformly.

High-alumina cement from phosphate rock and alunite. HERBERT H. MEYERS (to Armour Fertilizer Works). U. S. 1,791,103, Feb. 3. A mixt. of finely ground phosphate rock and finely ground alunite is calcined, and the calcined product is treated with NH_3, water and CO_2; the solid residue is sepd. from the soln., and the sepd. residue is burned to produce a cement of the high-alumina quick-hardening type. Cf. *C. A.* **24,** 5965.

Color composition for cementitious products. HERBERT E. BEDWELL. Can. 308,454, Feb. 10, 1931. A coloring compn. for cementitious material comprises 30 lb carbon black, 4 lb. Fe oxide and 100 lb. of water to form a paste capable of retaining the color suspended evenly throughout the mass. One lb. of oil of pine is preferably added.

Process for the regeneration of stones, marbles and concrete products. F. RICHIR. Belg. 371,673, Aug. 31, 1930. The material is impregnated with a metal fluosilicate contg. a slight excess of acid.

Apparatus for slaking the excess of lime in cement or clinker. ARTURO MALIGNANI and CAMILLO MALIGNANI. Ger. 514,474, April 3, 1928.

Rotary kiln for burning cement, ores, etc. LIONEL D. PARKER (to Vickers, Ltd.). U. S. 1,791,282, Feb. 3.

Concrete. VLADISLAV DYRYNK. Fr. 693,446, April 7, 1930. A silicate concrete is made by mixing a powd. basic silicate rock with a sol. glass and sand to make a mortar which is mixed with water and ground, and then broken stones or gravel are added.

Concrete grindstones for wood-pulp manufacture. F. RUHLEMANN. Brit. 335,521, June 21, 1929. The external temp. surrounding the stone is made equal to the internal temp. of the stone during its manuf. in order to avoid unequal stresses developing during the setting and hardening. Various details of manuf. are described.

Bituminous materials. ALUMINIUMERZ BERGBAU UND INDUSTRIE A.-G. Fr. 693,867, Apr. 14, 1930. Bituminous materials, particularly for roads, are made by incorporating finely divided bauxite with bitumen, etc. Other substances such as clay, schist, limestone or sand may also be added.

Road-surfacing material. SOUTH METROPOLITAN GAS CO., H. PICKARD and H. STANIER. Brit. 335,668, July 23, 1929. Coal, 1–10 lb., is dispersed in tar, 100 lb., (which may contain up to 10% of added pitch) at 250–300°, and 30–60% of dried and warm finely divided mineral matter is added and admixed.

Road-building aggregate. LESTER WITTENBERG (to Barrett Co.). U. S. 1,791,109, Feb. 3. Stone and bitumen are mixed while the bitumen is fluid and the stone has a temp. approx. equal to that at which the bitumen will set. An arrangement of app. is described.

Tar macadam. J. F. WAKE. Brit. 335,525, April 24, 1929. Aggregate is first coated with bituminous material and then with tar or a tar compn. comprising 20–75% of the total material in the 2 coatings, and a third coating of oil or low-viscosity tar also may be applied. The tar material used contains about 0.5% tar acids and 2% of naphthalene.

Roofing. G. F. JAULET and O. PARDOEN. Belg. 372,317, Aug. 31, 1930. Asbestos

is mixed and worked up with a vegetable oil together with a binder for the oxidizing substances, so that the asbestos fibers will be enveloped in completely hardened and oxidized oil.

Material suitable for shingles formed of cement and fibrous material. JOHN W. LEDEBOER (to Ambler Asbestos Shingle & Sheathing Co.). U. S. 1,790,822, Feb. 3. A material which may be formed mainly of cement and fibrous material is provided on its surface with a plurality of variably overlapping streaks comprising powdery coloring matter of different hues and cement irregularly distributed.

Drying stand for wood. OLOF ENGELBREKTSON. Ger. 515,459, Jan. 7, 1928.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND ALDEN H. EMERY

Fuel utilization in 1930. Fuel Research Inst. *J. Fuel Soc. Japan* 10, 4–36(1931); English abstr. 1–6.—A review. F. I. NAKAMURA

The utilization of Brazilian fuel. FRÉDÉRIC W. FREISE. *Chaleur et ind.* 11, 320–6 (1930).—The utilization of coal, coal washing and briquetting, powdered coal, carbonization, manuf. of metallurgical coke, gas manuf., and low-temp. carbonization in Brazil are generally treated. Lignites, bituminous schists and peat in Brazil are briefly mentioned. Liquid and gaseous fuels are also briefly treated. A bibliography of 15 references is given. S. L. B. ETHERTON

Fuels and their combustion. ROGER MARTIN. *Chaleur et ind.* 10, 149, 206–12 (1929). S. L. B ETHERTON

Some factors affecting the problem of smoke prevention. W. E. GIBBS. *J. Inst. Fuel* 3, 361–8(1930).—A theoretical discussion of the formation of smoke and its elimination by (1) gravity sepn., (2) pptn. by centrifugal force, (3) washing and (4) electrostatic sepn. D. A. REYNOLDS

The relative merits of coal and oil in the mercantile marine. W. M. MEIJEN. *J. Inst. Fuel* 4, 54–8(1930).—A discussion. D. A. REYNOLDS

Fuel problems in the mercantile marine. STERRY B. FREEMAN. *J. Inst. Fuel* 4, 48–53(1930). D. A. REYNOLDS

Fuel problems in the mercantile marine. W. J. MULLER *J. Inst. Fuel* 4, 59–63 (1930). D. A. REYNOLDS

Diesel-engine developments. MAXIMILIAN GERCKE. *J. Inst. Fuel* 4, 16–20(1930). D. A. REYNOLDS

Two important physical properties of fuels pertaining to the formation of mixtures in carburetor engines. WAWRZINIOK. *Automobiltech. Z.* 33, 292–4, 317–8, 364–6, 408–10, 478–80(1930).—The suitability of fuel such as gasoline, benzene, alc., etc., and their mixts., for carburetor engines is detd. by the "evaporation no." which is obtained by exposing the fuel to a temp. of 45° and a pressure of 80 mm., adding the time (in min.) required to evap. 5, 10, 15, 20, 25–95% of fuel and dividing by the number of time readings, *i. e.*, by 19. An app. constructed for this detn. by the author is described in detail. A. A. BOEHTLINGK

The utilization of gas oil in motor trucks. A. GREBEL. *Chaleur et ind.* 11, 277–85, 333–43(1930).—G. gives an account of Chilowsky's app. for oil gas. This gas contains CO_2 4.8, CO 13.8, H_2 8.6, CH_4 9.1, C_2H_4 4.4 and N_2 59.3%, and the thermal yield is 70%. The gas is fed to a four-cylinder motor and its performance is analyzed. The prepn. of gas oil by "the chemical carburetor" is described with sketches and data, and a general summary is added. S. L. B. ETHERTON

Methane as motor fuel. J. BRONN. *Brennstoff-Chem.* 12, 27–9, 45–7(1931).—Uses for the large amts. of coke-oven gas which have been freed of H, etc., for various industrial purposes are discussed from practical and economic viewpoints. Direct use as fuel for internal-combustion engines is proposed; previous attempts thus to employ gaseous fuels are reviewed. The combustion of CH_4 and homologs is examd., and analytical data for the exhaust gases from fuel contg. 80% CH_4 are given. Several months' road test indicates that 0.85 cu. m. CH_4 = 1.0 l. C_6H_6, that the motor is not injured and that less lubricating oil is required. Cost data are given for the use of various types of steel cylinders and high-pressure piping from plants to population centers. F. W. JUNG

Recent experiments on the pyrolysis of methane. R. V. WHEELER AND W. L. WORD. *Fuel in Science & Practice* 9, 567–74(1930).—Addnl. exptl. work on the pyrolysis of CH_4 is described (cf. *C. A.* 24, 5715). Two types of expts. were made, (1) in which

CH_4 was heated in a quartz bulb of 60 cc. capacity at different temps., pressure changes being observed by manometer readings and (2) in which large vols. of CH_4 were passed through heated tubes of different materials, the products of decompn. being collected and analyzed. The rapid initial decompn. of CH_4 is chiefly a surface effect, but the decompn. does not proceed to an equil. state by surface reaction because of the formation of a protective layer of adsorbed H on the silica surface, which leads to a false state of equil. Fe has no effect on the decompn. of CH_4 but at higher temps. it has a marked catalytic effect on the pyrolysis. Tars and C_2H_4 are produced during CH_4 decompn.; hence the reaction is complex. When CH_4 is decompd. by prolonged heating, C and H are the principal products. As the duration of heating is decreased, more of the decompd. CH_4 is converted into higher hydrocarbons; for periods of heating of 0.3 sec. at 1050° in a silica tube, 84% of the decompd. CH_4 produced higher hydrocarbons. The shortest periods of heating favor the formation of mols. of 2 C atoms, whereas on increase in the duration of heating these diminish, and aromatic compds. are formed. C_3H_6 and C_3H_2 were not detected among the decompn. products. CH_4 flowing through an Fe tube was completely decompd. into its elements at comparatively low temps., yielding a C deposit quite different from that deposited in tubes of SiO_2 or chrome-Fe. D. A. REYNOLDS

Liquefaction of methane according to recent investigations. JOZEF DUBOIS. *Przemysl Chem.* 14, 302–9(1930).—This is a review dealing principally with liquefaction of methane and production of motor benzines. It contains numerous patent and periodical literature references. A. C. Z.

Purification of acetylene. S. KAKUTANI AND A. YAMADA. *Repts. Imp Ind. Research Inst., Osaka, Japan* 11, No. 11, 78 pp.(1930).—A review on the method of removing impurities such as PH_3, H_2S and NH_3 in acetylene and some exptl. data are given. F. I. NAKAMURA

Calculation of the heating value of solid fuels. F. SCHUSTER. *Glückauf* 67, 232–5 (1931).—Proposed formulas, based on proximate and ultimate analysis and on air required for combustion, are reviewed and tested on typical coals, the detd. heating values being known. Formulas based on air required and on the proximate analysis give only roughly approx. results. Vondracek's formula, $H_O = 81C + 342.5H + 22.5S - 36.6O$ Cal./kg., and that of S., $H_O = (254 + 0.355O)\ [C/3 + H - (O\text{-}S)/8]$ Cal./kg., gave results within 2% of the detd. value. The tests covered bituminous coals, brown coals, peat and wood. J. D. DAVIS

Softening of ash of solid fuel. H. A. J. PIETERS. *Chem. Weekblad* 27, 331–4 (1930).—A modified app. for detg. the softening point of ash is described, and a large no. of results are recorded. Three classes are distinguished, with softening temps., resp., below 1250°, and above 1250°, the 3rd class showing softening but not melting above 1250°. The relationship between softening temp. and chem. compn. is discussed. B. C. A.

Powdered fuel, with special reference to Lancashire boilers. H. J. HILL. *Trans. Inst. Mining Eng.* (London) 80, 158–79(1930–31).—The max. fineness possible is the aim in prepg. pulverized fuel; however, 75–85% through 200-mesh is the usual size used. Air-float anthracite dust burned more freely than dust from a pulverizer. A microscopic examn. showed that the dust from the pulverizer was rounded whereas the float dust was angular and hence exposed more surface during combustion. Present-day burners for boilers and furnaces are designed to obtain max. turbulence and in most cases the shortest possible length of flame. The operation of 2 Lancashire boilers has been entirely satisfactory. C. W. OWINGS

Pulverized fuel for the small unit-shell type boiler, metallurgical and chemical processes. H. W. HOLLANDS AND E. C. LOWNDES. *J. Inst. Fuel* 3, 225–30(1930).—Pulverized coal is compared to oil and gas as a fuel in cement plants, road-tar plants and for evapn. in the manuf. of NaOH. D. A. REYNOLDS

Tests of a Ljungström air preheater with a chain grate stoker. W. SCHULTES. *Glückauf* 66, 11–7(1930).—Comparative tests were made on a Babcock and Wilcox water tube boiler of 122 sq. m. heating surface with and without the air preheater (regenerative) which was located at the rear of the boiler in the flue-gas canal. The fuel used was low grade, being a 1:1 mixt. of fine coal and coal of a medium grade. The mixt. gave 14–27% ash, about 14% H_2O and 5400 to 5700 cal. Mech. imperfections of the preheater caused considerable trouble. The main advantages were increased capacity and easy kindling of the low-grade fuel. It did not enhance clinker trouble. The operation of the preheater was not interfered with by dust (ash) in the flue gas. Complete test data are given. J. D. DAVIS

Low-temperature carbonization and the production of electricity in Germany.

P. ROSIN. *J. Inst. Fuel* 3, 189–98(1930); cf. *C. A.* 24, 223.—A review is given of the present trend in Germany toward the coupling of carbonization plant, power station and gas works. D. A. REYNOLDS

The x-ray stereoscopic examination of coal. ARTHUR N. WILSON. *J. Inst. Fuel* 3, 433; 4, 64–5(1930); cf. *C. A.* 24, 5969 D. A. REYNOLDS

The history and present position of coal investigation by oxidation. W. FUCHS. *Fuel in Science & Practice* 9, 581–6(1930).—A review. D. A. REYNOLDS

Rational sampling of coal for chemical analysis. K. KLING AND J. PFANHAUSER. *Przemysl Chem.* 15, 12–6(1931).—Directions and care to be exercised in taking samples of coal from geologic deposits, cars, classifiers, storage, etc., are given, and the method of prepg. and cutting down the large sample is described in detail. A. C. ZACHLIN

Apparatus for sampling powdered coal. D. J. W. KREULEN. *Chem. Weekblad* 28, 66(1931).—Sampling of a carload of powd coal with a shovel is inaccurate. A sampler is described made up from a can. A small hole in the bottom makes it possible to see if the can is full. E. SCHOTTE

Constant factors for the calculation of the calorific value of Cape Breton coals from proximate analysis data. J. L BOWLBY. *Trans. Can. Inst. Mining Met.* 32, 469–90 (1929).—A comparison of various formulas. The expression preferred is $Vx + 145.5C + 40.5S$ = B. t. u per lb., where V is the volatile matter, C the fixed C and S the S percentage, and x is an arbitrary const. depending on the colliery. B. C. A.

Apparatus for determining the tendency of coal and other materials toward spontaneous combustion. D. J. W. KREULEN. *Chem. Weekblad* 27, 690–4(1930).—See *C. A.* 25, 394. E. SCHOTTE

Determination of the expansion pressure of coal. H. NEDELMANN. *Brennstoff-Chem.* 12, 42–3(1931).—The app. of Baum and Heuser (cf. *Glückauf* 66, 1497–1502, 1538–44(1930)) has been improved to include hydraulic pressure measurement and other simplifications in recording, etc. The importance of coal moisture content, particle size and uniformity in filling the apparatus is stressed. Data are given to show the duplicability of results in tests. F. W. JUNG

The washing of coal on the Hoyois washer. ARTHUR GROUNDS. *Fuel Economist* 5, 561–4, 665–9(1930).—The Hoyois washer is based on a combination of the trough washer and the upward-current classifier. LESLIE B. BRAGG

Incombustibles in coal and slag formation. REINHARD SCHULZE. *Die Warme* 54, 81–5(1931).—Results of expts. are presented which indicate that in spite of practically the same ash content and heating value of the fuel, the combustion characteristics and especially the slag formation in large measure depend on the mineral chem. compn of the incombustible matter and on the particle size, d. and reaction velocity as well as on the kind of atm. in the burning charge. Greater Fe_2O_3 and CaO contents lower the slag m. p. of the fuel with the simultaneous presence of a mixed atm. and lead to the formation of a vitreous pasty slag. Coke in coarse granules can be burned without difficulty with a high output, while in smaller granules the same coke is almost unserviceable. ALLEN S. SMITH

Calorimetric investigations of slag. A I. KORELIN. *Izvestiya Teplotekh. Inst* (*Trans. Thermo-Tech. Inst. Russia*) 1930, No. 1, 22–8.—Calorimetric investigations of slag can be carried out in a bomb; a minimum of 15% of combustible material is required for an accurate detn. The combustion should be effected with an admixt. of an air-dry material low in ash and sulfur. Such material may be hard coal, anthracite, coke or wood charcoal. The bomb should be charged up to 40 atm. with O, and the slag should be moistened with mineral oil, crude oil, fuel oil, etc. Combustion in the presence of a mixt. of benzoic and salicylic acids or sugar generally does not give satisfactory results. The presence of some inorg. compds., such as a high percentage of carbonates, may affect the combustion values considerably. When burning a mixt. of slag and coal in the calorimeter, an excessive rise in temp. should be avoided. This would require a large amount of charging material, while working with small amounts produces sufficiently accurate results. A. A. BOEHTLINGK

Petrographic investigation of bituminous coal briquets. H. BODE. *Brennstoff-Chem.* 11, 476–8(1930); 12, 7–9(1931).—The briquetting of fine coals is discussed from the viewpoint of constitution, *i. e.*, the durain, vitrain and fusain contents. Briquets were made (*a*) from equal mixts. of high-volatile and low-volatile coals of various particle sizes, and (*b*) from a mixt. of the high-volatile and a pressed, low-volatile coal; the same amount of pitch was used in each case. Abrasion tests, as detd. in a tumbler, gave 22.5% of < 3 mm. size for the first mixt. and 15.5% of > 5 mm. size for the second. The effect of fusain content upon the pitch required is discussed at length, a contrast being noted with its effect upon the briquetting of brown coal. Distinction in fusain

effect is made for particle size, < 0.12 mm. requiring an unnecessarily greater amount of binder pitch. Air cleaning does not satisfactorily reduce fusain content by removing undesired dust. For the various coal-particle sizes of > 5 mm. to 0.088 mm. for the three coals used, analytical screen data are tabulated for fusain, vitrain, durain and mineral matter to demonstrate the increasing contents of the first two with increasing fineness. Magnified sections show the distribution of the aggregate in the briquets made. F. W. JUNG

Studies in the development of Dakota lignite. IV. Critical oxidation temperature of lignite. W. C. EATON, G. A. BRADY, A. W. GAUGER, IRVIN LAVINE AND C. A. MANN. *Ind. Eng. Chem.* **23**, 87–93(1931).—The authors describe a method used in the detn. of the CO_2 index and "critical oxidation temp." (C. O. T.) of lignite. The results of the expts. indicate: (1) in a comparison of lignite with other coals, an increase in indexes and C. O. T. with the rank of the coal; (2) a decrease in index and C. O. T. with a decrease in the water content of lignite; (3) a decrease in C. O. T. and an increase in index with decrease in particle size; (4) an increase in C. O. T. and index as gases are changed from O_2 to air, to N_2 and to no gas; (5) a decrease in both index and C. O. T. with increase in gas flow; (6) 80° to 90° as the temp. at which, under the conditions used, dry lignite begins to self-heat sufficiently to burn spontaneously; (7) no greater change in index and C. O. T. after processing by the Fleissner method than would be expected. M. C. ROGERS

Carbonizing and briquetting Saskatchewan lignite. W. G HEPTINSTALL. *Trans. Can. Inst. Mining Met.* **32**, 395–404(1929).—A detailed description of the use of the Lurgi process for lignite contg. 30% of moisture. B. C. A.

Fusain. S. W. PARR, H C. HOPKINS AND D. R. MITCHELL *Ind Eng. Chem., Anal. Ed.* **3**, 64 5(1931).—The modes of occurrence of fusain in Illinois coals are described. In selected lumps of freshly mined Ill. coals 2 kinds of fusain, "hard" and "soft," were noted. Proximate analyses on moisture-free basis of 11 samples of fusain from 3 different beds of Ill. coal and of face samples of coal from the same mines, and calcd. values for "unit volatile matter" of the fusains are tabulated. The most striking feature noted was the fairly consistent character, especially in B. t. u. values, of the fusain from all parts of the state. The high porosity of fusain was shown by its air-drying to 0.5–2% moisture, while coals from the same beds retained 2–6% moisture. This porosity of fusain accounts for the large absorption of water by some bituminous coals even though they do not slack. The av. "unit volatile matter" for the fusain was 20.44, which would appear to refute completely the forest-fire theory of its formation. W. W. HODGE

X-ray study of vitrains. C. MAHADEVAN. *Indian J. Physics* **5**, 525–41(1930), *Fuel in Science & Practice* **9**, 574–80; cf. *C. A.* **24**, 5982.—Paleozoic and Tertiary vitrains of varying compn. were examd. by x-ray diffraction methods. The halo spacings for the former were 3.37 A. U. for the inner and 2.12 A. U. for the outer halo. For the latter, the values 3.50 A. U. and 2.21 A. U. were obtained. The intensity of general scattering between the direct spot and the halos depends somewhat on the moisture content and volatile matter of the vitrains. A calcn. of the size of the diffracting particles indicates that they are of colloidal dimensions and that the mineral matter present is in a colloidal state. MALCOLM DOLE

Natural gas in 1929. G. R. HOPKINS AND H. BACKUS. Bur. of Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 319–40 (preprint No. 22, published February 3, 1931). E. H.

Proposed table of standards for technical fuel gases. J. KRZYZKIEWICZ. *Przemysl Chem.* **14**, 345–53(1930).—The 2 sheets of this table are reproduced and discussed. The first sheet shows the principle on which the gases are classified with respect to their origin, group, kinds and varieties, methods of prepn., brief descriptions of the varieties of the gases, and limits of their heat values. The second sheet covers addnl. technical names of industrial gases. A. C. ZACHLIN

The utilization of town gas as a fuel in heat-treatment furnaces. C. M. WALTER. *J. Inst. Fuel* **3**, 408–18(1930). D. A. REYNOLDS

Instruments aid in operating gas producers economically. JAY S. MCCLIMON. *Steel* **87**, 15, 54, 56, 58(1930) LESLIE B. BRAGG

Up-to-date methods for purifying illuminating gas before delivery to the consumers. A. V. Sivolobov. *Izvestiya Teplotekh. Inst. (Trans. Thermo-Tech. Inst. Russia) (Repts. of the 5th All-Russian Thermo-Tech. Congress)* 1930, No. 3, 73–100.—A general description of known methods. A. A. Boehtlingk

The Feld processes for the extraction of ammonia and hydrogen sulfide from coal gas. A. Parker. *Gas Eng.* 47, 694–5(1930).—P. discusses briefly Feld's processes for removing H_2S and NH_3 from city gas. The first process, consisting in the oxidation of H_2S by SO_2, was not successful because of the slow rate of the reaction. In the second process $ZnSO_3$ (from ZnO and SO_2) was used to oxidize the H_2S; the products (ZnS, S and water) could be treated with SO_2 to form ZnS_2O_3 and the mixt. again used to treat the gas. This process was unsatisfactory because of side reactions. The third process involved the removal of both H_2S and NH_3 by reaction with $FeSO_4$ to form $(NH_4)_2SO_4$, and further treatment producing Fe polythionates which decompose in the presence of water and NH_3. The difficulties with the above processes resulted in the development of a process using NH_4 polythionates for removing H_2S and NH_3 simultaneously. Also in *Inst. Gas Eng., Communication* No. 19, 4–8(1930). M. C. Rogers

Determination of carbon monoxide in illuminating gas. Jozef Dubois. *Przemysl Chem.* 14, 313–8(1930).—From a crit. examn. of the common methods of analysis D. finds those using Cu salts to be the best suited. The acid soln. of Cu_2Cl_2 absorbs CO rapidly but incompletely, while the ammoniacal soln. absorbs it completely though slowly. The best results are obtained by combining the 2 kinds of absorptions, allowing the acid soln. to take up 80% of the total CO content and removing the remainder in the ammoniacal soln. The method consists in first shaking the sample 2 min. with each of 2 successive 10 cc. quantities of the acid reagent, and then for 2 min. with each of 3 successive 5 cc. portions of the ammoniacal reagent. A complete absorption of CO takes place. The Damiens reagent was adopted for a complete and rapid absorption of CO over Hg. Three cc. of the reagent is introduced into the Hg pipet and shaken lightly for 9–10 min. Methods of prepg. the solns. are given. A. C. Z.

Atomizing and wick odorizers for natural gas. Philip E. Beckman. *Gas Age-Record* 66, 859–64, 886(1930).—A Venturi-type atomizer and a wick odorizer for odorizing natural gas are described in detail. Considerable exptl. work led to the choice of the present types of app. Leslie B. Bragg

New aspects of the gum problem. W. L. Shively. *Gas Age-Record* 66, 577–8, 584(1930).—Gum troubles have recently been noted with coal gas in pilot needle valves and thermostats. The gum is carried to the point of deposition as suspended particles of very small size. Preventive measures have been successfully applied but differ for individual situations. Leslie B. Bragg

Gum formation in town gas. L. H. Sensicle. *Gas Eng.* 47, 625–7(1930).—Gum forms in small droplets; continuous impacts against pipe walls and fittings assist these to deposit and form large drops. Volatilization of the lighter components causes the gum to become less fluid with increase in time. Gum deposits on valves in meters and deteriorates meter leathers. It stops up orifices in burners. Causes of gum formation and requirements of effective inhibitors are discussed. M. C. Rogers

Flue-gas testing. H. D. Brasch. *Die Wärme* 54, 57–9(1931).—A mech. Orsat type of continuous flue-gas analyzer is described. The percentages of CO_2 and combustible gases are indicated and are recorded on a strip chart. Details of the construction of the instrument and of its installation are given. Allen S. Smith

Combustion temperature and flue-gas composition; their determination with regard to dissociation. Roman Selikin. *Die Wärme* 54, 51–3(1931).—A method of detg. the flue-gas compn. and combustion temp. of any gas mixt. by means of the chem. equil. const. is discussed. When the gas contains no CH_4, the calcns. are simple. If CH_4 is present, the method is applicable if the fact is taken into consideration that CH_4 is not stable at high temps., but dissociates into its constituents which burn to CO_2 and H_2O. The combustion of an illuminating gas with $^3/_4$ the theoretically required air is used as an example. Allen S. Smith

Determination of viscosity on small samples of tar. F. M. Potter and J. S. Sach. *Roads* 8, 231–2(1930).—The app. described by Mallison (*C. A.* 15, 1231) is shown to provide a rapid means of checking the viscosities of tars, and the precautions necessary to obtain consistent results are discussed. B. C. A.

The thermal decomposition of the low-temperature tar of Fushun coal. I. Tadashi Mizoshita. *Abstracts from Rept. Central Lab. S. Manchuria Ry. Co.* 1929, 33–5.—A yield of 13.5% anti-knock gasoline is obtained by cracking at 430° and 25–30 atm. V. F. Harrington

The utilization of high-temperature coal-tar pitch. I. Preparation of creosote-oil substitute from pitch. MUNENARI TANAKA, KIYOSHI MORIKAWE AND ISAO MORIKAWA. *Abstracts from Rept. Central Lab. S. Manchuria Ry. Co.* 1929, 29–32.—Gasoline-solvent naphtha mixts. (1 : 1) dissolve 46% of the pitch. This ext. mixed with creosote oil is used as a creosote-oil substitute. **II. The preparation of active carbon from the extraction residue of high-temperature pitch.** SUSUMU WATANABE. *Ibid* 32–3. Calcining with K_2SO_4 gives a C more active than any commercial product. V. F. HARRINGTON

The desulfurization of brown coal tar oils with brown coal low-temperature coke. C. STAEMMLER. *Brennstoff-Chem.* 12, 43–5(1931).—Methods proposed and developed during the past year are reviewed. Attempts were made to desulfurize a generator light oil of 0.46% S, its distillate of 0.42% S, and a "yellow" oil of 0.72% S, by distn. over dried coke of 3–4 mm. size in an electrically heated tube furnace. While the H_2S from S compds. decomposed at the higher temps. was removed completely, the S removed was consistently small with a max. of less than 40% of the total S. Distn. in a stream of air or H had no effect. Pretreatment of the coke with HCl did not effect removal of the S, but it discolored the distillate with colloidal matter. Pptn. of $CaCO_3$ in the coke increased the S removal to 50% but is not believed practical. F. W. J.

The agglutination of coal and the activation of its surface during coke formation, considered as two complementary phenomena. W. SWIETOSLAWSKI. *Fuel in Science & Practice* 9, 564–6(1930).—The necessity of thorough impregnation of an inert material with caking material if the agglutinating ingredients of the latter are to be used effectively is stressed. The formation of structured surfaces on the stable products of dry distn. is held to be a converse process to that of the production of well-cemented coke. D. A. REYNOLDS

A comparison of methods for testing the caking properties of coal. L. SLATER. *Fuel in Science & Practice* 9, 586–91(1930).—See *C. A.* 24, 3625. D. A. REYNOLDS

Coking a banded bituminous coal: the part played by each band. C. P. FINN. *Trans. Inst. Mining Eng.* (London) 80, 283–302(1931).—Exptl. results show that different samples of clarain, which forms the largest percentage of the banded ingredients present in coking slack, may vary considerably in their coking properties but yield a comparatively poor coke that is much fissured and breaks easily. Evidence available indicates that vitrain is proportionately more valuable than clarain in a coking slack. Durain appears to exert little effect. Fusain, although itself non-coking, has been shown to be valuable when uniformly admixed with the remainder of the coking slack in amts. $< 5\%$. An increase in the amt of fusain middlings does not have any beneficial effect, and there is an indication from the tests that their complete removal may be advantageous. The presence of free dirt is deleterious to the quality of the coke obtained. C. W. OWINGS

Production of low-sulfur coke in the Ekaterinov ore area. V. M. STAKHOVSKII AND R. M. IL'EVA-RATNER. *J. Chem. Ind* (Moscow) 6, 734–5(1929).—Crushed coal from the Almaz vein graded on a 3-mm screen was found to show lower ash and S contents in the fines than in the coarse material. A. C. ZACHLIN

The dry cooling of coke. JENS RUDE. *Engineering* 130, 543–4(1930).—The thermal advantages of dry-cooling coke are outlined, and it is calcd. that the recoverable sensible heat is slightly less than 4% of the B. t. u. of the coke taken as 11,000 B. t. u. per lb. Section diagrams of the Sulzer dry coke-cooling plant are given. In this process inert combustion gases circulate through the hot coke and to a steam generator all in a closed system. Cooling time varies from 3.5 -4 hrs. for a large capacity plant to 1.5 hrs. for small gas works where the car of coke (1.5 tons) is wheeled directly into the cooling chamber. The essential features of the Collin dry-cooling plant are also outlined. The advantages of dry coke-cooling are: better quality coke, no water to evap. when the coke is burned, a smaller amt. of fines and breeze and recovery of the sensible heat of the coke. The chief objection is the high cost for a plant of the large dimensions required because of the comparatively low temp. gradients existing throughout the process. A set of curves is given showing the relative heat-transfer rates from coke to boiler water. Apparently a saving of approx. $^1/_3$ in the cost of the plant could be secured by cooling the coke to only 450–500°, but some 20% less steam would be produced than by cooling to about 300° as is now done. Two systems using steam (*C. A.* 24, 5466) in place of the inert gases are outlined and their relative advantages discussed. W. W. HODGE

Determination of volatile matter in coke. A. P. SHAKHNO AND M. D. ZHUKOVSKAYA. *Izvestiya Teplotekh. Inst.* (*Trans. Thermo-Tech. Inst. Russia*) 1930, No. 2, 17–26; cf. *C. A.* 24, 1721.—Results obtained by the use of alc., gas and elec. heating equipment are compared. A. A. BOEHTLINGK

The use of anhydrite (calcium sulfate) in the production of ammonium sulfate. P. PARRISH. *Gas Eng.* **47**, 695–6(1930); cf. *C. A.* **22**, 4768.—P. discusses the production of $(NH_4)_2SO_4$ by the action of $(NH_4)_2CO_3$ on $CaSO_4$. The carbonation and reaction with $CaSO_4$ must be carried out in sep. vessels. This increases the reaction rate and prevents side reactions. Four vessels in series are required. Also in *Inst. Gas Eng., Communication* No. 19, 9–24(1930). M. C. ROGERS

Rapid method for determination of benzene and phenol in ammoniacal and waste liquors. W. MÜNZ. *Brennstoff-Chem.* **12**, 3–4(1931).—To det. C_6H_6, pass upward through a vertical tube, 30 cm. long and 5 cm. in diam., contg. 100–150 g. activated charcoal, 10 l. of the liquor to be tested, in 1 hour's time. Drain the charcoal, recover the C_6H_6 by means of superheated steam by the method of Kattwinkel (cf. *C. A.* **24**, 1252) and det. to 200° by the usual procedure. This method is accurate only up to a charcoal absorption of 15% C_6H_6 by wt. To det. PhOH measure into a 250-cc. distn. flask 25 cc. of the filtered liquor. Add ammoniacal $CuSO_4$ soln. (prepd. by adding concd NH_4OH in excess to cold satd. $CuSO_4$ soln.) in excess of pptn. and then 5 cc. 40% NaOH soln. Boil over a free flame with shaking until NH_3 vapors are no longer evident, connect the flask to a condenser and pass CO_2 through the soln. at the rate of 2–3 bubbles per sec. The neutralization should be complete after some 5 min. Distil to dryness with a slow stream of CO_2. Rinse the condenser, adapter, etc., into the 250-cc. volumetric flask used as receiver and make up the distillate to vol. For titration, 25 or 50 cc of this is used in the case of NH_3 liquors, but with waste liquors the whole may be necessary. To this in a stoppered Erlenmeyer flask add 25 cc. of 0.1 *N* KBr-KBrO$_3$ soln. and then 15 cc. 15% H_2SO_4. After $^1/_2$ hr. add 10 cc. of 10% KI soln., let stand $^1/_4$ hr., and titrate the excess, using starch indicator, with 0.1 *N* $Na_2S_2O_3$ soln.

Fuel briquets. H. J. M. WASTEELS. Belg. 371,152, July 31, 1930. The coal is placed in iron or steel molds which are then placed in the distg. retorts. After distn. the balls, briquets or blocks of coke are demolded.

Fuel briquets. LUDWIG WEBER. U. S. 1,791,077, Feb. 3. Particles to be briquetted such as fuels, ores or flue dust are mixed with very finely divided clay of great plasticity, and this mixt., before briquetting, is moistened with sulfite waste liquor.

Production of agglomerates without the addition of pitch. H. HARDY. Belg. 370,410, June 30, 1930. Coal or lignite is prepd. in a globular state with a view to soln. in solvents acting successively; *e. g.*, the globular coal is treated with heavy oils, solvent naphtha and benzene, either in the above or reverse order; the coal can be carbonized at low temp., to obtain a powdered fuel, or it can be first pressed to agglomerate it and then carbonized for the production of semi-coke. Cf. *C. A.* **24**, 4615.

Plant for the manufacture of smokeless fuel. COMPAGNIE DES MINES DE VICOIGNE NOEUX ET DROCOURT. Fr. 693,273, May 30, 1929.

Fuel for internal-combustion engines. JOHANN W. MICHEEL. Ger. 515,076, Jan. 9, 1929. Soot from solid, liquid or gaseous fuels is compressed into briquets and then finely ground.

Motor fuel. I. G. FARBENIND. A.-G. Fr. 692,594, Mar. 24, 1930. When starting liquid fuel of high vapor tension is fed to explosion motors by mech. pressure on spongy material contg. the fuel.

Gasifying wet bituminous fuels. HERMANN HILLEBRAND. U. S. 1,791,411, Feb. 3. Alternately operated regenerative chambers are heated by burning a portion of recirculated gas; a mixt. of recirculated gas and steam is superheated in one of the heated regenerative chambers and thence passed upwardly into a gasification zone of a fuel bed to form water gas; a portion of the water gas and recirculated gas is passed through a superposed distn. zone of the fuel bed, effecting distn. of gases and vapors from the fuel; another portion of the water gas and recirculated gas is passed in heat exchange

with the wet fuel and to a collecting main, and the distn. gases and vapors are recirculated through the regenerative chamber. App. is described.

Low-temperature carbonization of bituminous carbonaceous materials. I. G. FARBENIND. A.-G. Brit. 335,740, Sept. 30, 1929. In a process such as described in Brit. 301,975 (*C. A.* **23**, 4329) in which hot gases are blown through fuel so that it is maintained in active motion on the grate, to effect carbonization without combustion or gasification, impact devices are arranged over the fuel bed to limit the upward movement of the fuel. Various details of app. are described. Cf. *C. A.* **24**, 489.

Low-temperature carbonization of powdered fuel. F. L. DUFFIELD. Brit. 335,643, July 5, 1929. In the use of a horizontal retort using steam as the carrying medium, the retort is locally heated to a high temp., and steam is admitted tangentially to the heated surface. Various details of structure of the app. and of its operation are described.

Process and oven for the distillation or low-temperature carbonization of coal and other carbonaceous materials. C. HONNAY. Belg. 370,266, June 30, 1930. Constructional features.

Vertical retort for low-temperature carbonization of fuel. CHARLES TURNER. Ger. 515,388, Mar. 20, 1928. See Brit. 295,461 (*C. A.* **23**, 2276).

Distilling solid fuels. FRANK E. HOBSON. Ger. 515,386 and 515,387, Feb. 3, 1927. See Brit. 277,214 and 277,215 (*C. A.* **22**, 2455).

Distilling solid carbonaceous materials in oil. IMPERIAL CHEMICAL INDUSTRIES, LTD. Ger. 515,389, Oct. 28, 1928. See Brit. 305,744 (*C. A.* **23**, 5032-3).

Furnace for the low-temperature distillation of carbonaceous materials. CHARLES HONNAY. Fr. 693,038, Mar. 29, 1930.

Rotatable retorts for the low-temperature distillation of coal. THE CARBOCITE CO. Fr. 692,881, Mar. 28, 1930.

Apparatus for distilling coal for the production of coke. BABCOCK & WILCOX, LTD. Fr. 692,529, Mar. 21, 1930.

Apparatus for carbonizing comminuted coal and for enriching water gas with distillation products. EDWARD A. DIETERLE. U. S. 1,790,745, Feb. 3. Structural features.

Destructive hydrogenation of coals, tars, etc. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 335,543, June 24, 1929. Various carbonaceous materials, which may be mixed with phenolic substances or like O-contg. compds. are first treated with CO or gases contg. CO at elevated temps. and preferably under pressure to effect removal of most of the O present, and are then subjected to a treatment with H. Water present in the initial material may react with the CO to form H and effect partial hydrogenation. Various details of procedure, catalysts used, etc., are given. Cf. *C. A.* **25**, 1362.

Purifying gas. HUMPHREYS & GLASGOW, LTD. Fr. 693,106, April 1, 1930. Gases are freed from S by bringing the gases into contact with a heated catalyst formed of ZnO with or without an activating agent, whereby the org. S compds. are decomposed forming H_2S which is eliminated. The undecomposed org. S compds. are removed by H_2SO_4. Cf. *C. A.* **24**, 1726.

Desulfurizing gases. RICHARD BRANDT. Ger. 514,666, Dec. 15, 1927. Addn. to 503,118. In removing H_2S from gases by means of $K_3Fe(CN)_6$ soln. which is regenerated as described in Ger. 503,118 (*C. A.* **24**, 4994), the desulfurizing soln. is used in a continuous cycle without filtering off the free S liberated from the gases, the cycle including a settling vessel in which the agglomerated portion of the originally colloidal S is sepd.

Dehydrating fuel gas. FREDERICK W. SPERR, JR. (to Koppers Co.). U. S. 1,791,086, Feb. 3. Gas such as coke-oven or water gas is compressed, cooled by direct contact with water at substantially atm. temp. so that a portion of the moisture carried by the gas is removed, and the compressed and cooled gas is then treated with a hygroscopic material such as $CaCl_2$ or H_2SO_4 for further removal of moisture. An arrangement of app. is described.

Gases containing hydrogen. I. G. FARBENIND. A.-G. Brit. 335,524, April 24, 1929. In the conversion of carbonaceous materials such as CH_4, coal distn. gases, tars, mineral oils, etc., into gases consisting mainly of H and CO or of these gases and N, by treatment with air, O or CO_2 (with or without steam) in an elec. arc furnace, devices such as narrow exit openings produce eddies which cause all parts of the gas mixt. to attain a temp. of at least 1400°. Various details of app. and procedure are described.

Oil gas. CONSTANTIN CHILOWSKY. Ger. 514,487, Mar. 25, 1926. See Fr. 679,107 (*C. A.* **24**, 3888).

Mixed oil gas and water gas. H. G. TERZIAN (to Humphreys & Glasgow, Ltd.). Brit. 335,495, July 11, 1929. In a process in which oil gas is passed through an ignited fuel bed and the deposited C is consumed in the water-gas reaction, steam is generated in the tar washer by the passage of hot oil gas, and the steam thus formed is used in the generator to form water gas. Various details of app. and procedure are described. Cf. *C. A.* **25**, 1063.

Water gas. HUMPHREYS & GLASGOW, LTD. Fr. 693,105, April 1, 1930. Water gas is made by passing steam upwardly through a mass of incandescent fuel from a point situated sufficiently above the base of the mass to leave an annullar zone of incandescent fuel. A part of the gas produced is raised through a superposed layer of fresh fuel to eliminate hydrocarbons, another part is passed into a carburetor where it is mixed with a hydrocarbon, and the mixt. is introduced at the center of the lower part of fresh fuel.

Water gas. POWER GAS CORPORATION, LTD., and NIELS E. RAMBUSH. Fr. 693,514, Apr. 8, 1930. Means is described for superheating the steam, which is passed alternatively in an ascending and in a descending direction through the fuel. Cf. *C. A.* **24**, 3888.

Water gas. HENRY O. LOEBELL (to Henry L. Doherty). U. S. 1,790,824, Feb. 3. Fuel is passed downwardly in an unobstructed column of circular cross section through a gas-generating zone in which high temps. are maintained by periodically blasting air in a substantially radial direction through incandescent fuel in the zone. Steam is passed through incandescent fuel in the high temp. zone during periods following the air blasting, and hot water gas thus formed is passed through fuel above the blast zone. App. is described. Cf. *C. A.* **25**, 582.

Apparatus for manufacture of water gas. HENRY O. LOEBELL (to Henry L. Doherty). U. S. 1,790,823, Feb. 3. Structural features.

Water-gas producer. SOC. ANON. LA CARBONITE. Fr. 693,289, July 8, 1929.

Device permitting of the use of high-volatile or mixed high- and low-volatile coal fines in gas producers. E. DOHET. Belg. 370,238, June 30, 1930. A circular rotating plate is placed above the producer. The fuel is fed on to this plate and allowed to stay there sufficiently long to become agglomerated before it is fed into the producer. The gases given off from the coal while on the plate are mixed with the producer gas.

Apparatus for producing coal gas and water gas from coal dust. KARL MEITZLER. Ger. 514,486, Sept. 4, 1925.

Ovens for producing gas and coke. STETTINER CHAMOTTE-FABRIK A.-G. VORM. DIDIER. Ger. 515,385, Dec. 11, 1928. Constructional features are described.

"Waterless" gas holder. R. & J. DEMPSTER, LTD., J. W. SCOTT and WATERLESS GASHOLDER CO., LTD. Brit. 335,502, Feb. 15, 1930.

Purification and desulfurization of benzene. C. PETIT. Belg. 371,908, Aug. 31, 1930. The benzene vapors are bubbled through liquors such as H_2SO_4, NaOH or Na_2CO_3, which may be made to flow over the trays of a benzene-rectifying column or of a column placed after the rectifying column.

Storing acetylene. F. ROFFEY and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 335,820, Nov. 28, 1929. C_2H_2 is stored in cylinders or other containers contg. a solid absorbent material impregnated with an C_2H_2-solvent comprising a relatively non-volatile ether, ester or ether-ester of a polyhydric alc. such as glycol diethyl ether, glycerol triethyl ether, glycol diacetate, glycerol triacetate, β-ethoxyethyl acetate, β,γ-diethoxy-*n*-propyl acetate, glycol monoacetate, glycerol diacetate, glycol monoethyl ether and glycerol diethyl ether or mixts. of these. Before storing, the C_2H_2 is preferably dried, as by passing over $CaCl_2$ before and after compression. Some other suitable solvents are also mentioned.

Phenols. HUILES, GOUDRONS ET DÉRIVÉS and GEORGES SUPRIN. Fr. 693,734, July 22, 1929. Phenols obtained in phenolic oils and tars are extd. by solns. of alkali carbonates at a high temp. under pressure, means being provided to remove the CO_2 formed. This CO_2 is used for acidification of the phenolates obtained to reform carbonates.

Tar refining. JEAN H. BREGI (to Compagnie Technique des Petroles). U. S. 1,791,052, Feb. 3. See Fr. 689,294 (*C. A.* **25**, 1064).

Apparatus for distilling tar, oils, etc. COMPAGNIES RÉUNIES DE GAZ ET D'ÉLECTRICITÉ. Fr. 693,681, April 10, 1930.

Coking pitch. C. OTTO & Co. G. M. B. H. Ger. 514,478, Feb. 19, 1928. A finely

ground mixt. of pitch and pitch coke is coked in an oven of refractory material, the walls of which are coated with pitch coke to prevent penetration by the pitch.

Coke oven and door. CARL STILL. U. S. 1,790,775, Feb. 3. Structural features.

Method and plant for dry-cooling coke. WILHELM KLEISSER. Ger. 514,410, Nov. 18, 1925.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

Municipal regulation of oil storage. ROBERT S. MOULTON. *Quart. Natl. Fire Protect. Assocn.* **24**, 255–76(1931).—A thorough review of the fire hazards of petroleum products and their control in cities, accompanied by a list of N. F. P. A. publications bearing on the subject. C. L. JONES

Catalytic reactions of sulfur compounds present in petroleum. I. High-sulfur naphthas in contact with nickel and iron catalysts. J. C. ELGIN, G. H. WILDER AND H. S. TAYLOR. *Ind. Eng. Chem.* **22**, 1284–90(1930).—Reduced Ni removed S from naphthas in both the liquid and the vapor states. The catalyst was most effective in its action upon the first of the naphtha vapor passed over it. Its activity then dropped off till a "steady state" was reached and its effect was almost const. for the remainder of the run. The S content of the naphthas was reduced still more if H_2 was passed with the naphtha vapor over the Ni. The action of reduced Fe was similar to that of Ni, but less pronounced. **II. Pure sulfur compounds in hydrocarbon materials in contact with nickel catalysts.** J. C. ELGIN. *Ibid* 1290–3.—Solns. of BuSH, iso-BuSH, Pr_2S, $(iso\text{-}Bu)_2S$ and thiophene in naphtha were passed in vapor form over reduced-Ni catalysts at 300°. The mercaptans readily decomposed, giving up S as H_2S. The sulfides reacted less readily. Thiophene was not affected after the catalyst had reached the steady state unless H_2 was passed with the naphtha vapor. Thiophene is formed in the thermal decompn. of mercaptans and sulfides; hence the removal of S from cracked naphthas is likely to be more difficult than from straight-run. EMMA E. CRANDAL

Refining of light petroleum distillates. H. P. RUE AND RALPH H. ESPACH. Bur. Mines, *Bull.* **333**, 111 pp.(1930).—Proper fractionation of the gasoline from a pressure distillate will decrease the amt. of chem. treatment necessary to make the gasoline meet trade requirements. To get the max. benefits of fractionation on the chem. treatment, a good degree of sepn. is necessary; there should be no overlaps in distn. range. In fractionation units, a reflux (closed-coil or open-spray) at the top of the bubble tower is necessary to control the top temp. When a closed-coil reflux is used, incoming charging stock may be preheated by pumping it through the coil. When an open-spray is used, the refluxing medium should be the material that is taken overhead as a vapor. The present methods of treating light distillates are described in detail. The influence of time, temp. and thoroughness of contact in treating with H_2SO_4 is considered. The effects of acid treatment on C deposits, distn. range, gravity and color are shown. The use of alkali is discussed. Studies with S and S compounds dissolved in gasoline are described. The effect of fractionation on color and gum formation is discussed. ALDEN H. EMERY

Refining cracked distillates. JACQUE C. MORRELL. *Natl. Petroleum News* **22**, No. 51, 61–6, No. 52, 49–54, No. 53, 46–8(1930); **23**, No. 1, 63–72, No. 2, 57–8, No. 3, 51, 54, 58, 60(1931).—The following are discussed: the desulfurization of cracked distillates by different methods; theory of gum formation; use of gum inhibitors for gasoline to be stored; H_2SO_4 treatment; split plumbite treatment; refining by sludge acid; recovery of spent chemicals at the refinery; acid and "doctor" soln.; rerunning acid-treated distillates; soap washes; vapor-phase treating; treatment of end point cracked distillates without rerunning; continuous treating plants; mixing devices; settling tanks and sepg. devices; gasoline treating plants; distn. equipment; operation of shell stills; operation of shell still rerun units; pipe still rerunning; operating precautions; chem. factors in distn.; future possibilities. R. W. KELLY

The occurrence of higher fatty acids in mineral oil distillates. E. HOLZMANN AND STANISLAUS VON PILAT. *Brennstoff-Chem.* **12**, 41–2(1931).—The cryst. material previously (cf. *C. A.* **25**, 584) sepd. from the phenol-free naphthenic-acid fraction of petroleum has been identified as higher fatty acids, although work by others indicated their absence in Polish oils. More of this material was prepd. from a Boryslav machine oil by dehydrating and distg. the acidified Na_2CO_3 washings to 235–40° at 12–15 mm. Hg in a

new Burstin-Winkler app., shown schematically, and sepg. the distillate into the acids, phenols and hydrocarbons. The first fraction yielded the fatty acids upon cooling. After removal by centrifuging, recrystn. from MeOH and then from acetone, white crystals were obtained. A mixed m. p. identified them as arachic acid. This characterization was confirmed by the neutralization no., the mol. wt. by m. p. depression and the elementary analysis. Additional fatty acids sepd. from the mother liquor as Li salts give a total of 0.0013% for the crude petroleum. They are being investigated further. F. W. JUNG

Present-day tendencies in oil-fuel burning. JOHN L. STREVENS. *Fuel Economist* 5, 569–72, 623–4(1930).—A review. LESLIE B. BRAGG

The value of ash determinations of mineral and fatty oils. W. SCHAEFER. *Seifensieder-Ztg.* 57, 878–9(1930).—The org. S in oils usually enters the ash on burning, indicating the presence of sulfates or sulfides in the oil. An extn. with H_2O or acid does not furnish evidence of the presence of these compds. P. ESCHER

Crystallization of paraffin wax. E. KATZ. *J. Inst. Petroleum Tech.* 16, 870–88 (1930).—The cryst. form of Polish and Asiatic wax crystd. from various solvents is shown by a microscopic study to be fundamentally a six-sided plate. Sixty-two photographs illustrate the variations of this form. L. W. T. CUMMINGS

Evaluation of anti-knock properties of fuels. L. AUER. *Automobiltech. Z.* 33, 538–9(1930).—A review. A. A. BOEHTLINGK

Velocity of propagation of flame and pressure wave: thermodynamic consideration of motors and the phenomenon of detonation. E. VARETON AND U. RE. *Ann. scuola ing. Padova* 4, 226–40(1928).—A review of the literature and of the work done, chiefly by American and English workers. S. L. B. ETHERTON

Experiments to determine velocities of flame propagation in a side-valve gasoline engine. H. S. GLYDE. *J. Inst. Petroleum Tech.* 16, 756–82(1930).—It is known that small head clearance in an explosion engine tends to reduce detonation and that differences of head clearance cause variations of turbulence. The possible relation of velocity of flame travel to head clearance and to turbulence forms the subject of this study. Measurements of the velocity of flame movement were taken in an engine with side-valve low-turbulence combustion chamber, and in 3 turbulent-type Ricardo engines with head clearances of 0.022, 0.084 and 0.272 in. Castings of the several combustion chambers used could be bolted down to a single cylinder block. Six sight holes in a straight line were made in the top of each combustion chamber and fitted with glass windows. A disk 16 in. in diam. revolved in a horizontal plane over the combustion chamber, on a vertical shaft connected with the ignition-timing shaft. Its radius was such that the line of holes cut in it from center to circumference would coincide with the line of openings into the combustion chamber. Its timing was adjustable by a screw. With the engine running, the usual readings of speed, torque, fuel consumption, ignition advance and jacket temps. were made at the same time as the observations through the stroboscopic disk. By the use of the adjusting screw, the time at which the flame passed each window could be known in terms of crankshaft degrees before or after the top dead center. Pressure-indicator diagrams were made. All runs were at 900 r. p. m. Max. velocity of the flame was reached in all cases within 7° and 10° after the top dead center. This was also the zone of max. rate of pressure rise. The smaller the head clearance, the more rapidly the velocity of the flame fell off after reaching it. This was attributed to the higher surface-vol. ratio, by which the flame was cooled and its travel impeded. The same cause raised the H. U. C. R. also. The mean velocities in the 4 heads were proportional to the rate of pressure rise, which is taken as the measure of turbulence. The max. velocities were nearly proportional, with the exception of that in Head No. 2. The velocity with which the flame spread from the spark to the first window was also proportional to the rate of pressure rise or turbulence. EMMA E. CRANDAL

Synthetic lubricating oils. A. W. NASH, H. M. STANLEY AND A. R. BOWEN. *J. Inst. Petroleum Tech.* 16, 830–69(1930).—Expts. are reported on the polymerization of C_2H_4 to light and heavy oils by heating in an autoclave at pressures up to 60 atm. Without a catalyst the polymerization occurred only above 325°. The temp. was lowered to 230–275° with $ZnCl_2$ as a catalyst and to 180° with $AlCl_3$, which was the principal catalyst studied. The product consisted of free oil (I) and hydrocarbon associated with the $AlCl_3$ (II). (I) contained from 10 to 45 C atoms and was of a satd. character, while (II) contained 10 to 50 C atoms per mol. and was unsatd. The products were distilled and some of the properties of the fractions reported: b. p., Br no., d., viscosity, and change of d. on oxidation. The heavier fractions had practically the

same characteristics as com. lubricants, except that they were more readily oxidizable. L. W. T. CUMMINGS

Recent examinations of friction and lubrication. J. E. SOUTHCOMBE. *Teknisk Ukeblad* **75**, 354–8(1928).—A review with subsequent discussion. C. A. ROBAK

About germ process oil. SVERRE LAUNY. *Teknisk Ukeblad* **75**, 388–9(1928).—A reply to Southcombe (see preceding abstract). Since the fatty acids which are used to make germ-process oil attack metals slightly with the formation of soaps, L. asks for more detailed information, particularly in regard to the variation of the coeff. of friction with time. C. A. ROBAK

The stability of germ-process oils. JAMES E. SOUTHCOMBE. *Teknisk Ukeblad* **75**, 507–8(1928).—A reply to Launy (cf. preceding abstr.). The fatty acids used for germ-process oil in amts. of about 0.7–1.0% are very pure, and accordingly have only a very small chem. activity. The standard test for germ oil is to heat 200 g. of oil to 80° for 36 hrs. in contact with steel plates. No change in color or wt. of the metal takes place. Comparative tests with germ oil and mineral oil carried out by heating both to 80° with Cu foil for 36 hrs., show that the wt. of the Cu foil is reduced a little more in germ oil than in pure mineral oil. The reduction is still higher in compound marine oil contg. rapeseed oil, which has been used extensively in ships for more than 25 years. C. A. ROBAK

The stability of germ oils. SVERRE LAUNY. *Teknisk Ukeblad* **76**, 10–1(1929).—A reply to Southcombe (cf. preceding abstr.). Even the tables given by Southcombe show that the addn. of "germ" to an oil always increases the corrosive action of the oil. The amt. of Cu dissolved was increased by 58 and 50% in 2 expts. C. A. R.

Dielectric losses of oils. A. GEMANT. *Z. tech. Physik* **11**, 544–5(1930).—By recent articles of G. (*Wiss. Veröffentlich. Siemens-Konzern*, in press) and of Ornstein and Willemse (*C. A.* **25**, 9), it is shown that the loss curves for transformers oils consist of 2 super-imposed parts (loss angle, ϑ, *versus* frequency). For high frequency the Debye losses are most important, but at low frequency the Wagner effect preponderates. B. J. C. VAN DER HOEVEN

Determination of the drop point by means of the Ubbelohde apparatus, especially for high-temperature lubricants. P. SCHWARZ. *Seifensieder-Ztg.* **57**, 877(1930).—The detn. of the drop point for greases and solid lubricants by means of the Ubbelohde app. may give values that differ by 25°, due to differences in the diam. or length of the glass tubing and to the depth to which the thermometer bulb is immersed. The rate of heating and moisture in the high-temp. lubricants also influences the results. P. ESCHER

Improved asphalt extractor. T. E. STANTON. *Eng. News-Record* **106**, 38(1931).—A new type of extractor is described in which the solvent is passed through an alundum filter stone 1 in. thick with the aid of 90-lb. air pressure. The max. variation between the asphalt content used and extd. from 11 prepd. samples contg. a high % of 200-mesh material and asphaltic cement was 0.2%, the av. variation being less than 0.03%. The solvent used is $CHCl_3$, approx. 85% of it being recovered. The cost of solvent per sample is about 13¢. The time of extn. with oil or asphaltic concrete mixts. is 15–30 min. R. E. THOMPSON

Filtration of asphaltic precipitates by suction, permitting rapid determinations. PAUL WOOG AND JEAN GIVAUDON. *Bull. soc. chim.* [4], **47**, 1419–20(1930).—Powd. glass that passes through a sieve of 0.058 mm. mesh is used in a crucible with sintered-glass bottom for filtering asphalt The process is rapid and gives const. results. G. M. MURPHY

A study of gum turpentines. (MISS) MARCELLE BARRAUD. *Bull. inst. pin* **1930**, 217–24.—The yield of spirit of turpentine from gum produced by pines of the same species or of species yielding spirit of turpentine having approx. the same compn. is fairly uniform, provided that the trees are situated in the most favorable conditions for growth. Spirit of turpentine consisting of pinene and nopinene can be obtained in yields exceeding 25%, but usually 22–23%. Spirit of turpentine contg other terpenes than pinene and nopinene is obtained in somewhat lower yields (20% or less). The first gatherings of gum contain more spirit of turpentine than the later ones. Trees of large diam. tend to give more gum contg. a higher proportion of spirit of turpentine than small trees. Analysis of 300 samples, each representing at least 1 tank-car of spirit of turpentine from Bordeaux pine, gave α_J —28.98° to —32°; spirit of turpentine from Austrian black pine had α_J —15.83° to —33.27°. α_J was for Austrian pine and maritine pine, resp., —17.50° to —37.14°, +10.12° to —38.86°. By fractionation of highly *l*-rotatory maritine-pine spirits of turpentine in a 2-m. Lebel column, pinene was sepd. having $[\alpha]$ —51.13°, while the highest values previously reported by Dupont

were +50.92° for pinene from Aleppo pine and —48.70° for pinene from maritine pine. A similar study of spirits of turpentine from Aleppo pine would probably yield a pinene having [α] higher than +50.92°. A. PAPINEAU-COUTURE

Two important physical properties of fuels, pertaining to the formation of mixtures in carburetor engines (WAWRZINIOK) **21.** Petroleum insecticides (WOODWORTH) **15.** Limestone oil reservoirs of the northeastern United States and of Ontario, Canada (MURRAY) **8.** Some properties of limestone as a reservoir rock (HOWARD, LOVE) **8.** Study of the black shale overlying the cap rock of the Cromwell sand in relation to the origin of the Cromwell oil dome, Oklahoma (GRAWE) **8.** Some chemical aspects of the origin of petroleum (LIND) 8. Hydrocarbons (Fr. pat. 693,054) **10.**

Treating cold petroleum oils with sulfuric acid. HORACE B. SETZLER and MERT C. MCDONALD (to National Refining Co.). U. S. 1,791,329, Feb. 3. The temp. of the oil is reduced to about 5° and the oil, during continued agitation, is subjected to the action of H_2SO_4, and clarified oil and sludge are sepd. App. is described.

Cracking petroleum oils. DAVID G. BRANDT (to Doherty Research Co.). U. S. 1,791,114, Feb. 3. In cracking oil under pressure, charging stock is passed in heat interchange relation to, but out of contact with, vapors in a dephlegmator so that a reflux condensate is produced; this condensate is passed through a heater under pressure to produce highly heated oil and vapors. The highly heated vapors and oil are sepd. in a sepg. zone, and the highly heated vapors are passed under pressure into a body of oil to crack the latter; residuum is withdrawn from the body of oil last mentioned and is distd. and the resulting distillate is independently heated under pressure to a high temp. and is passed into the sepg. zone. App. is described. Cf. *C. A.* **25,** 411.

Cracking crude petroleum. GENERAL TECHNICAL CO., LTD. Fr. 693,286, July 4, 1929. The asphaltic residues obtained in cracking crude petroleum are heated with a chem. reagent such as baryta and Fe perchloride to about 300°, under a pressure below 6 kg., and the products are returned to the cracking operation to be converted into gasoline.

Cracking and destructively hydrogenating hydrocarbons. I. G. FARBENIND. A.-G. Brit. 335,522, April 23, 1929. The process described in Brit. 296,700 (*C. A* **23,** 2555) is modified by subjecting the carbonaceous material to a mild cracking process in which extensive formation of benzine is avoided, followed by sepn. of any benzine formed and destructive hydrogenation of the remaining material. Catalysts may be employed in both these stages, if catalysts having a splitting action such as bauxite, silica gel, active charcoal or alumina are used for the initial stage. Numerous details and modifications of procedure are described, and an example of the process as applied to gas oil treatment is given.

Cracking hydrocarbons. JEAN F. A. BRUZAC. Fr. 693,281, June 22, 1929. Heavy hydrocarbons are converted to lighter hydrocarbons in 2 operations. (1) The hydrocarbons are distd. in contact with neutral metals such as Fe, Cu or Ni and condensed by cooling, the temp. never being above 500°. (2) The hydrocarbons from the first are submitted to the action of O or ozone to remove excess of C and S.

Cracking hydrocarbons. OWEN D. LUCAS. Fr. 692,549, Mar. 21, 1930. In converting heavy oils to light oils the temp. of the oil to be treated is raised to the final temp. required for cracking or conversion by communicating the necessary heat to the oil by indirect contact with biphenyl or phenyl ether in the liquid state in a heat exchanger, this compd. being contained in a closed-circuit app. to which the heat is furnished apart from the heat exchanger. Before entering the heat exchanger the oil is heated directly to a temp. below that at which appreciable cracking takes place.

Hydrocarbons of low molecular weight from those of high molecular weight. N. V. BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Dutch 22,573, Sept. 15, 1930. The reaction is accelerated by metal carbides (Ca, U, Mo, Al). The temp. is between 300° and 700°; increased pressure may be used. No H_2, H_2O or H-contg. vapors are used.

Cleavage of hydrocarbons boiling up to 40°. N. V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Dutch 22,574 Sept. 15, 1930. Low-boiling hydrocarbons, propane, butane, etc., are cracked in the presence of a small quantity of catalyzer (org. or inorg. halide, as HCl, CHI_3, CCl_4, $POCl_3$, etc.) with or without activator (Cu, Fe). Temps. of around 600° are used.

Distilling heavy hydrocarbon oils. ROGER D. HUNNEMAN, FRANCIS M. ROGERS and ROBERT E. WILSON (to Standard Oil Co. of Ind.). U. S. 1,791,209, Feb. 3. Oil such as residual oil is heated to about 355–405° and steam at a like temp. in the pro-

portion of 3–10 lb. per gal. of final oil distillate is supplied. Equilibrium is established between the oil and steam while maintaining an absolute pressure not over 75 mm., and the unvaporized oil and vapors are sepd. App. is described. Cf. *C. A.* **24**, 3353.

Gasoline by fractional condensation. DAVID G. BRANDT (to Doherty Research Co.). U. S. 1,791,113, Feb. 3. Hydrocarbon vapors contg. gasoline constituents, such as vapors produced by distg. and cracking petroleum, are passed under superatm. pressure through a series of condensing zones, the last of which is maintained at substantially the normal atm temp. while preceding zones are maintained at a higher temp., and condensates obtained in the preceding zones are individually cooled to substantially normal atm. temp. and a body of cooled condensate having a higher mean b. p. than that of the condensate obtained in the last condensing zone is maintained and mixed with the condensate from the last condensing zone. An arrangement of app. is described.

Gasoline from fuel oil. L. DE POTTER and F. RASQUIN. Belg. 370,471, June 30, 1930. Fuel oil is treated under pressure in a closed vessel with a compressed gas. The mixt. thus obtained is purified in filtering app. arranged in a closed circuit.

Apparatus for producing gas from gasoline. JAMES T. JONES (to Norman A. Way, Carley Zelmenovitz and Ashton Burford). U. S. 1,791,213, Feb. 3.

Filter for gasoline, etc. AMALGAMATED CARBURETTERS, LTD., and C. BROWN. Brit. 335,693, Aug. 26, 1929. Structural features.

Filter for gasoline, etc. WM. J. VILLAVASO. U. S. 1,791,333, Feb. 3. Structural features.

Filter for oil of internal-combustion engines. ERNEST J. SWEETLAND. U. S. 1,791,046, Feb. 3. Structural features.

Apparatus for dehydrating oil. LEONARD D. GRISBAUM (to Railway Service and Supply Corp.). Can. 308,563, Feb. 10, 1931.

Solutions of lower mercaptan compounds. GERALD L. WENDT (to Standard Oil Co. of Ind.). U. S. 1,791,179, Feb. 3. A soln. of lower mercaptan compds. which is suitable for removing S from gasoline, etc., is prepd. by washing petroleum naphtha with a NaOH soln. and adding to the resulting soln. a Ca compd., such as lime or Ca hydrosulfide, which reacts with the Na sulfide present to ppt. the sulfide radical.

Bituminous emulsions. BITUMULS KALTASPHALT A.-G. (C. A. Braun, inventor). Ger. 514,485, Mar. 22, 1925. Stable emulsions of asphalt and other bituminous materials and ceresin are prepd. by supplying the material to be emulsified, together with alk. water contg. less than 1% of alkali, to a mixing vessel contg. a pre-formed emulsion of the material. The amt. of emulsion that can be so prepd. from the batch of pre-formed emulsion is stated to be practically unlimited. Examples are given. Cf. *C. A.* **24**, 4627.

Reclaiming journal box lubricating oil from waste. LEONARD D. GRISBAUM (to Railway Service & Supply Corp.). U. S. 1,791,473, Feb. 3. Contaminated emulsified oil is treated with an alk. soln. such as NaOH of sufficient strength to break the emulsion and react with contaminations including lint, at a temp. above 75° (preferably about 100°), the mixt. is agitated with air, mixed with water, further agitated with air and the oil is sepd. App. is described. U. S. 1,791,474 describes app. and detail of procedure for treating the contaminated oil with NaOH soln. and projecting water on the surface of the oil after subsidence of the mixt., to travel downwardly. Cf. *C. A.* **24**, 6001.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Determination of alpha cellulose. H. PINCASS. *Kunstseide* **12**, 282–3(1930).—Cellulose materials analyzed for alpha cellulose by 3 different methods gave different values. The differences in the results are due mainly to differences in the preliminary drying of the sample and to differences in the methods of washing out the alkali and drying the alpha cellulose. FREDERICK C. HAHN

Measuring the viscosity of cellulose and its application to the manufacture of plastics. L. LAISNEY AND H. RECLUS. *Rev. gén. mat. plastiques* **7**, 3–15(1931).—After a brief review of previous work on the viscosity of cellulose, a technic for its detn. is described in detail. The method is simple and easy to use in a com lab., and is sufficiently accurate for ordinary purposes. The cuprammonium soln. is prepd. via Joyner (*C. A.* **16**, 3543), but the NH_4OH is strengthened to about 250 g. NH_3 per l. before soln. of the Cu and again after soln. of the Cu is completed. The cellulose is dissolved in the

presence of H_2, and the soln. is forced by pressure of H_2 into a H_2-filled tube, where the viscosity is detd. by the falling-sphere method (a 3-mm. sphere falling 50 cm.). The concn. of the soln. should be such as to give a viscosity of 5–100 sec. The viscosity at various concns. was found to be: 0%, 2 sec.; 1%, 10 sec.; 2%, 140 sec.; 3%, 1000 sec. These values practically correspond to the equation $\log V = 1.01\ C + 0.035$.

A. PAPINEAU-COUTURE

Production of ammonium copper oxide cellulose solutions. E. SCHURZ. *Kunstseide* **12**, 283–5(1930); *Jentgen's Rayon Review* **2**, 248–9(1930).—A detailed discussion of the prepn. of cellulose cuprammonium solns. involving the following steps: pptn. of $Cu(OH)_2$, mixing of the $Cu(OH)_2$ with cellulose, extn. of the blue liquor, soln. of the $Cu(OH)_2$ cellulose mixt. in ammonia, filtration of the resulting soln., and removal of air bubbles therefrom. The mixing of dry cellulose with solid $Cu(OH)_2$ results in a much better control of the spinning soln.

FREDERICK C. HAIN

Nitrates of cellulose benzoate. M. SENDO AND J. KONDO. *Cellulose Ind.* (Tokyo) **6**, 150–5(1930).—Cellulose monobenzoate was treated at 18–20° with mixed acids of the following percentage compn., resp., H_2SO_4, HNO_3, HNO_2 and water: (1) 71.14, 20.81, 0.13, 7.92; (2) 65.6, 18.1, 0.15, 16.15; and (3) 59.58, 21.39, 0.23, 18.8. Cellulose dinitrate mononitrobenzoate $[C_6H_7O_2(NO_3)_2CO_2C_6H_4NO_2]$ was obtained by means of acids (1) and (2) and the mononitrate $[C_6H_8O_3(NO_3)CO_2C_6H_4NO_2]$ by acid (3). The explosive properties of these nitrates are similar to those of the normal cellulose nitrates, but, compared with equally nitrated normal cellulose, these mixed esters are more stable, less hygroscopic and less soluble in ether-alc. and burn at a slower rate.

B. C. A

Acid adsorption and stability of nitrocellulose. D. R. WIGGAM. *J. Phys. Chem.* **35**, 536–9(1931).—HNO_3 and H_2SO_4 are adsorbed by nitrocellulose of high N content, other acids are adsorbed somewhat less. The stability of the nitrocellulose is lowered to a degree depending upon the amt. of acid adsorbed.

MALCOLM DOLE

Phenomena of the lattice transformations of nitrocellulose. Their generality in cellulose compounds. J. J. TRILLAT. *Compt. rend.* **191**, 1441–3(1931).—Trogus, Hess and Katz (*C. A.* **24**, 2877) have shown that the x-ray interference pattern of ramie fibers, nitrated to a max., is changed if the fibers are swelled by certain liquids. The altered pattern reverts reversibly to that of the original fiber as the liquid evaporates from the fiber. Cotton, nitrated to 12.95% N (nearly trinitrocellulose), gave a cryst. diagram corresponding to trinitrocellulose. Some of this nitrated cotton was then completely dispersed, instead of merely being swelled, by dissolving it in acetone, and was then recovered in the form of a film by evapn. of the acetone. The films showed a cryst. structure having a new lattice spacing of 9.31 A. U. and differing slightly in other respects from that of the undispersed cotton. It is uncertain whether this modification of the structure of the lattice corresponds to a new cryst. form of trinitrocellulose, or arises from a combination of the trinitrocellulose with the solvent. The film retains about 1% of acetone very tenaciously. The new diagram appears to be a mixture of that of the original trinitrocellulose with that of a new product. If the degree of nitration of the cotton is less (10–12%), the fibers show a cryst. structure, although more feebly as the degree of nitration is less. The corresponding films, however, show only halos corresponding to an amorphous structure. This difference between the films from cotton nitrated to 12.95% and to 12% is quite sharp. It appears that only trinitrocellulose is a well-defined compd. capable of crystallizing in a second form as the result of passing through the disperse phase. The presence of an ill-defined compd. such as "dinitrocellulose" hinders the process and gives rise to an amorphous structure. Similarly, cellophane is cryst. and has a structure different from that of the initial cotton. In general, it follows that the compd. of cellulose and native cellulose both can assume different cryst. forms after being passed through a state of swelling, followed by dispersion.

R. H. LOMBARD

α,β-Lignin. PETER KLASON. *Svensk Kem. Tids.* **42**, 259–63(1930).—Reply to Hägglund's contention that there is only one lignin in wood (cf. *C. A.* **24**, 5152, 6007).

A. R. ROSE

Utilization of hardwoods for mechanical and chemical pulp. H. S. HILL. *J. Forestry* **28**, 1146–52(1930).—As spruce becomes more expensive, hardwoods become more important as pulp raw material. That the pulping qualities of hardwoods have already been investigated and found to be satisfactory for a variety of pulp products is evident from the literature reviewed by H. The future use of hardwoods for pulp is essentially a matter of economics.

ALFRED L. KAMMERER

Wood fibers. G. J. RITTER. , *J. Forestry* **28**, 533–41(1930); cf. *C. A.* **22**, 4149; **23**, 976, 1931.—The results of an investigation of the microstructure of the fibers of 16 species of wood are presented. Two types of lignin are distinguished. Fiber cell walls

are made up of layers, capable of being sepd. into fibrils by chem. and mech. means. Fibrils in turn can be chemically sepd. into fusiform bodies. Cellulose and lignin from wood can be distinguished by their optical properties in polarized light. A. L. K.

Composition of Cassia siamea, L. Y. SHINODA. *Cellulose Ind.* (Tokyo) **6**, 155–6 (1930).—The following percentage compn. has been found: moisture 11.2, ale.-benzene ext. 18.2, lignin (König) 37.3 (on the extd., dry product), ash 0.3, impure cellulose 40.3, hydrolysis value (Ost) 92.8 and pentosan content (Tollens-Krüger) 15.6%. Before chlorination the wood meal was steeped in 10% NaOH soln. for 48 hrs. and its cellulose content redetd., when the value 33.8%, of purity 100%, was found. Xylose and mannose were found in the hydrolysis liquor, but no galactose was present. B. C. A.

Bamboo. I. Fine structure of the bamboo fiber. K. SISIDO. *Cellulose Ind.* (Tokyo) **6**, 148–50(1930).—A theoretical discussion of the results of previous workers. B. C. A.

The use of microörganisms in certain commercial processes. E. E. HUBERT. *J. Forestry* **28**, 542–5(1930).—A résumé is given of making com. products with the aid of molds, bacteria, yeasts, etc., with bibliography. Expts. have shown that spruce and balsam fir attacked by the group of fungi causing white rots may produce relatively large yields of pulp by the sulfite process. This finding has possibilities in the future development of pulp manuf. H. is carrying out expts. on the action of a blue stain fungus on western yellow pine, the resulting by-product of which has com. possibilities. ALFRED L. KAMMERER

Removal of hemicelluloses from wood by use of sodium hydroxide. O. HORN. *Cellulosechemie* **11**, 151–2(1930).—Mineral acids and 5% NaOH have been used to remove hemicelluloses, undesirable impurities in wood investigations. In the presence of NaOH, lignin may be oxidized or its components may be split off, perhaps through sapon. and the balance may be altered. Beechwood sawdust, after extn. with benzene-ethanol, 1:1, was degummed with 5% NaOH by 4 treatments at room temp. for 36 and for 48 hrs., the ext. after each treatment being removed and new alkali used. The av. wt. loss for 4 detns. was 23%. If no lignin is removed, a lignin content of 24.1% before degumming must rise to 29.6%, whereas experimentally, it was found to be a little over 27%. Methoxyl content for the wood before degumming was 6.25%, equiv. to 7.7% for degummed wood, whereas experimentally only about 6.3% was found. Each alkali treatment was followed by washing with cold water, dil. AcOH and hot water until the filtrate was colorless, the results in all expts. being fundamentally the same. Conclusion: The method for degumming by use of 5% NaOH is a suitable one because, in addn. to hemicelluloses, a part of the lignin is also removed. C. A. BRAUTLECHT

Quality of technical caustic soda employed in the manufacture of viscose silk. V. I. SHARKOV. *J. Chem. Ind.* (Moscow) **6**, 1027–9(1929).—The purity of NaOH for use in viscose silk manuf. is of the utmost importance. Practical experience has shown that the presence of NaCl + Na_2CO_3 in NaOH in greater concns. than 3.5–4% is harmful, although very low concns. are not markedly bad. These 2 salts exert about an equal depressing effect on the swelling of the fiber of sulfite cellulose. A. C. ZACHLIN

Cellulose acetate rayon. KRÜGER. *Kunstseide* **12**, 262–7(1930).—A review of recent scientific works related to the prepn. of cellulose acetate, discussion of these results in the light of present practice in the manuf. of cellulose acetate rayon, and a comparison of this rayon with other types of rayon from various standpoints. FREDERICK C. HAHN

Dry spinning of acetate rayon. FRITZ OHL. *Kunstseide* **12**, 279–81(1930); *Jentgen's Rayon Review* **2**, 245–7(1930).—Numerous factors influencing the production and quality of acetate rayon are discussed. A cellulose acetate should be chosen with the smallest possible structure of the cellulose molecule; it should be sol. in proper solvents, free from impurities, of uniform viscosity and should not contain over 0.05% H_2SO_4. The spinning soln. must be prepd. under the strictest conditions. A cellulose acetate of fixed moisture content must be used; it should be uniformly dissolved with a min. period of stirring to avoid warming the mixt. and loss of solvent. A no. of filtrations are required and all bubbles must be removed from the soln. prior to spinning. Exptl. data are presented showing the importance of the foregoing factors. In the dry spinning process a careful control of the quantity and temp. of the air is important. F. C. HAHN

Strengthening of rayon. TATSUMI YAMADA. *Repts. Imp. Ind. Research Lab., Osaka, Japan* **11**, No. 10(1930).—Absorption of water by cellulose depends upon the presence of a free OH group and by replacing it with NO_2 or AcO groups it is possible to increase the resistivity toward water. A similar result is obtained by treating rayon with formalin. Y. found the following conditions necessary to treat rayon with formalin:

p_H 1.2–2.0, time of immersion 12 hrs., time of heating 5 hrs. at 50–70° and concn. of soln. 4–10%. F. I. NAKAMURA

Mechanical advances in the artificial silk industry. HANS SCHMIDT. *Chem. App.* 17, 205–7, 230–2(1930).—A review. M. C. ROGERS

Beating of [paper] pulp. XI. A characteristic of vegetable fibers as paper-making materials. M. NAKANO. *Cellulose Ind.* (Tokyo) 6, 144–7(1930); cf. *C. A.* 24, 5491.—Wool, silk, asbestos and vegetable fibers were beaten, and their paper-forming properties compared. Wool cannot be split longitudinally but is reduced to short lengths showing no fibrillation, from which it is impossible to form a sheet. Silk and asbestos split up into fibrils, but the sheets formed from the products are weak because of the slippage of the fibers. It follows, therefore, that fibrillation is not necessarily accompanied by the development of the adhesive properties which are essential for the production of satisfactory sheets. Only vegetable fibers have these characteristic properties, which are due to the colloidal state of the surface of the fibrils, and their felting capacity is of secondary importance. B. C. A.

Beating of [paper] pulp. XII. Improvement of absorbency of blotting paper. M. NAKANO. *Cellulose Ind.* (Tokyo) 6, 164–7; *Abstracts* 29(1930); cf. preceding abstract. —Blotting papers of high absorbency are obtained by the use of pulps treated with concd. NaOH solns., and the absorbing velocity of such products is, on the av., about 40% higher than that of paper made from untreated pulp. Hence pulps can be transformed into "freer" states than their natural ones, and this effect is the reverse of that obtained by beating. B. C. A.

The utilization of kaoliang stalk. III. Industrial experiments on the manufacture of soda pulp and paper. RYUJI YAMAMOTO. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 26–7.—70% kaoliang pulp is used to make white or Manila paper. V. F. HARRINGTON

LEJEUNE-JUNG, PAUL: **Aus dem Werdegang der deutschen Zellstoff-Industrie 1880-1930.** Festschrift zum 50 jährigen Bestehen des Vereins deutscher Zellstoff-Fabrikanten e. V. Berlin: Selbstverlag d. Vereins. 112 pp. M. 10.

Cellulose. ERIK HÄGGLUND. Ger. 515,018, June 10, 1927. In the manuf. of cellulose by digesting wood with NaOH soln., a part of the black liquor by-product is returned to the digester, without causticizing, after its org. constituents have been destroyed by heating it to about 350° under 200 atm. pressure.

Cellulose. ERNST MEZEY. Ger. 514,466, Feb. 20, 1930. A pure, highly voluminous cellulose is prepd. by heating com. cellulose for 3–4 hrs. at 3–5 atm. pressure with a dihydric aliphatic alc. or a deriv. thereof, particularly a mono- or di-alkyl ether or an acetate or chloride. A small quantity of a weak alkali, *e. g.*, borax or soap, may also be present. Thus, washed sulfite cellulose may be heated as above with ethylene glycol monoethyl ether 2 and NH_3 0.5%, and the product washed and bleached.

Cellulose. HANS KAMMERL. Fr. 693,005, Mar. 29, 1930. A valuable cellulose is obtained from soiled plant fibers, particularly cotton waste such as linters, by treating the fibers mechanically to remove the greater part of the impurities in a centrifuge without a screen, after which the pectins, waxes and greases buried in the structure of the fiber are removed by leaching or light boiling.

Drying cellulose. GUSTAV NEUMANN. Fr. 693,014, Mar. 29, 1930. Cellulose is dried by means of liquid SO_2 which is then extd. by lowering the pressure. The dried cellulose is particularly suitable for acetylation or to be transformed into viscose.

Acidulation of cellulose. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 693,800, Apr. 12, 1930. Cellulose is acidulated by treating it first with concd. solns. of neutral salts such as $CaCl_2$, $MgCl_2$, $ZnCl_2$ or thiocyanates of K, Ca, etc., and then with anhydrides of aliphatic acids. Cf. *C. A.* 24, 3112.

Nitrating cellulose, etc. I. G. FARBENIND. A.-G. (Franz Becker and Hans Zepter, inventors). Ger. 515,108, Oct. 30, 1927. A small addn. of urea is made to the nitrating mixt. in order to eliminate or reduce the amt. of N_2O_3. The process is particularly useful in nitrating cellulose with relatively dil. nitrating mixts.

Cellulose esters. I. G. FARBENIND. A.-G. (Max Hagedorn and Georg Hingst, inventors). Ger. 515,106, Jan. 7, 1927. Sol. cellulose esters of higher fatty acids are prepd. by treating unpretreated cellulose with chlorides of the acids in the presence of pyridine, quinoline or like base at a temp. above 100°, *e. g.*, 110–140°. Diluents may be present. An example is given.

Cellulose esters. I. G. FARBENIND. A.-G. (Max Hagedorn and Georg Hingst, inventors). Ger. 515,107, Jan. 28, 1927. Insol. or difficultly sol. cellulose esters of higher fatty acids are converted into sol. esters by treatment in a liquid medium at a raised temp. not exceeding 200° with an org. or inorg. acid, acid anhydrideor acid salt, or mixts. of these. Thus, insol. cellulose tristearate gives a clear soln. when heated in $C_2H_2Cl_4$ with Cl_3CCOOH to 145°, and the ester, isolated by pouring the soln. into EtOH, is sol in C_6H_6, $CHCl_3$ and AcOAm. Other examples are given also. Cf. *C. A.* 25, 1379.

Cellulose esters. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 693,189, Apr. 2, 1930. Cellulose esters of fatty acids are made by heating esterifiable cellulosic material in vapors of a fatty acid having more than one and less than 8C atoms, at a temp. above 100° but below 200° in the absence of O and catalysts producing a degradation of the cellulose, until the acyl group in the ester thus produced has reached at least 4%, the said vapors being the sole acylating agent. The ester may be esterified afresh with addnl. acyl groups.

Benzylcelluloses. JOSEPH BOUCHET. Fr. 693,318, July 12, 1929. Aralkylcelluloses, and particularly dibenzylcellulose, are obtained by treating alkali cellulose prepd. with a concd. NaOH lye with $C_6H_5CH_2Cl$ at 70–100° without pressure and with or without a diluent.

Cellulose acetate. OSWALD SILBERRAD and HARRY BLEASDALE. Fr. 693,568, Apr. 9, 1930. The AcOH is recovered from the acetylation mixt. by adding to this mixt. an amt. of water greater than that necessary to destroy all the anhydride remaining, *e. g.*, an addn. of 6–8% of water. The mixt. is allowed to stand at 30–35° until the cellulose acetate has become sol. in acetone, then transferred to a distg app. and finely ground AcONa is intimately mixed with it, and the AcOH distd. off. Fr. 693,569 describes the manuf. of cellulose acetate in which the cellulose acetate is pptd. from an acid product and collected as a porous opaque substance by dilg. the acid product with water in amt. almost sufficient to start the pptn. and afterward bringing the acid product thus treated into contact with water so that from the moment of contact the product is submerged in an excess of water.

Cellulose acetate. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 693,132, Apr. 1, 1930. Cellulose acetate is prepd. by treating a cellulosic material with Ac_2O and a catalyst in the presence of a mixt. which dissolves the cellulose acetate produced, the mixt. contg. an amt. of AcOH insufficient, by itself, to dissolve the acetate and an org. volatile liquid not miscible with water and inert with regard to Ac_2O, *e g.*, $C_2H_4Cl_2$. The cellulose acetate is pptd. in an aq. bath at a temp. above the b. p. of the volatile liquid, which is collected and condensed. Fr. 693,133 describes the recovery of cellulose acetate from soln. in AcOH by mixing the soln. with an aq. pptn. bath contg. at the beginning at least 20% by wt. of AcOH and capable of pptg. the acetate.

Cellulose acetate compositions. SOC. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 693,131, Apr. 1, 1930. A compn. suitable for making films is made by dissolving cellulose acetate sol. in acetone in a volatile solvent mixt. composed of AcOMe 50, AcOEt 10–40 and acetone 40–10 parts. This soln. contains about 30% of cellulose acetate.

Apparatus for circulating and storing colloidal solutions of cellulose. SOC. INDUSTRIELLE DE MOIJ. Fr. 692,647, June 24, 1929. The app. is constructed so that the cellulose is brought in a perfectly homogeneous state to the spinning nozzles for making *artificial silk*.

Saccharification of cellulose. MAURICE JUNIEN. Fr. 693,277, June 14, 1929. Cellulosic materials are heated under pressure to remove free O and then hydrolyzed with hot dil. H_2SO_4 in the presence of excess of water to obtain fermentable sugars. An app. is described with means for keeping the acid in rapid movement during the hydrolysis.

Carbohydrate esters. I. G. FARBENIND. A.-G. (Max Hagedorn, inventor). Ger. 515,109, Feb. 11, 1928. See Fr. 668,686 (*C. A.* **24**, 1650).

Nitrocellulose solutions, etc. JOSEPH G. DAVIDSON (to Carbide and Carbon Chemicals Corp.). U. S. 1,791,301, Feb. 3. Nitrocellulose or a like cellulose deriv. is used with a solvent comprising the acetate of the monoethyl ether of ethylene glycol or other solvent of the same type.

Felted cellulose fiber products. GEORGE L. SCHWARTZ (to E. I. du Pont de Nemours & Co.). U. S. 1,791,248, Feb. 3. In forming products such as those suitable for

manuf. of "artificial leather," shoe box toes, etc., continuous bands of cellulose fibers are gelatinized with caustic alkali, the gelatinized fibrous material is subjected to heat and pressure and washed. App. is described.

Plastic compositions comprising cellulose esters and polymerized vinyl compounds. CELLULOID CORP. Brit. 335,582, March 23, 1928. Cellulose acetate or other cellulose esters are used with polymerized vinyl compds. such as polymerized vinyl aceate, propionate, phthalate, phosphate, chloride or bromide, styrene or the products obtained by dehalogenating vinyl halides as by use of Zn, with or without various plasticizers or softening agents, fillers, pigments, gums, resins, etc., or anti-acid substances such as urea or Ca lactate or volatile solvents.

Plastic masses. I. G. FARBENIND. A.-G. Fr. 693,496, April 7, 1930. Plastic masses are composed of derivs. of cellulose such as acetylcellulose in combination with a gelatinizing or plastifying agent formed of one or more esters of phosphoric acid, the org constituent of which consists of monoalkyl or monoaryl glycolic ethers of the ethyleneglycol, propyleneglycol or butyleneglycol series, such as dimethylglycolbutylglycolphosphate or dipropylglycolbutylglycolphosphate. Several examples are given.

Pyroxylin sheets. THE FIBERLOID CORP. Fr. 693,186, April 2, 1930. Smooth sheets of pyroxylin are made by transforming a gel of pyroxylin into a sheet while still plastic, and modifying the phys. state of the surface of the sheet while drawing. The sheets may be extended and submitted to a tension while extending and a part at least of the solvent is removed by warm air.

Molding celluloid sheets and articles. H. DE HEN. Belg. 369,941, June 30, 1930. Previously heated and softened celluloid sheets are simultaneously pressed and subjected to the action of chemicals and of evapn. until they have acquired the desired shape and such a consistency that they can be removed from the press without being cooled.

Viscose. LEON LILIENFELD. U. S. 1,790,990, Feb. 3. Cellulosic material such as cotton or wood-cellulose is treated at least once with a caustic alkali soln. contg. not less than 15% caustic alkali (calcd. as NaOH), washed, converted into alkali cellulose, and the alkali cellulose is converted into viscose. Cf. *C. A.* **24**, 2292.

Nontransparent and glossy capsule of regenerated cellulose. KALLE & Co. A.-G. (Julius Voss and Otto Schnecko, inventors). Ger. 515,377, Nov. 7, 1925. See U. S. 1,778,096 (*C. A.* **24**, 6014).

Artificial silk from viscose. ZELLSTOFFFABRIK WALDHOF and A. BERNSTEIN. Brit. 335,605, June 27, 1929. In a noncontinuous process of the type in which the thread, after coagulation and fixing, is collected on spools, acid is removed by passing the threads immediately after coagulation through a hot water bath, and the threads are then spooled. The coagulating bath may be formed of water 70, Na_2SO_4 13, H_2SO_4 10 and glucose 7%, and formalin may be added to the hot water bath.

Artificial silk from viscose. I. G. FARBENIND. A.-G. Brit. 335,675, Nov. 8, 1928. Viscose made from unripened alkali cellulose and contg. excess of alkali as compared with its content of cellulose is spun into a soln. of an NH_4 salt such as $(NH_4)_2SO_4$ to which acid and other NH_4 salts such as the acetate or formate may also be added, as may also other neutral salts such as Na_2SO_4, NaCl, NaOAc or Na lactate, etc. For subsequent coagulation, the formed threads are passed through an acid bath of low concn. such as a 6% H_2SO_4 soln. and the freshly pptd. threads may be subjected to stretching. The viscose is made from unripened cellulose at temps. above 0°. Cf. *C. A.* **25**, 814.

Artificial silk. COMPTOIR DES TEXTILES ARTIFICIELS. Brit. 335,613, June 28, 1929. In forming filaments such as those from viscose spun into an acid-salt bath, the partly coagulated filaments after leaving the coagulation bath are stretched by passage through a narrow tube through which flows a current of liquid (which may be the same as, or different from, the coagulation bath) offering resistance to the forward movement of the filaments as they are drawn by rollers or other devices. App. is described.

Artificial silk. ZELLSTOFFFABRIK WALDHOF and A. BERNSTEIN. Brit. 335,606, June 27, 1929. While passing from a twisting spool to a reel, the material is allowed to fall into a liquid bath preferably contg. a material such as a wax-oil emulsion which forms a protective coating on the filament. The app. is described. Precipitants which do not crystallize out are preferably used in the spinning process.

Artificial silk. BENNO BORZYKOWSKI. Fr. 693,700, April 11, 1930. See Ger. 492,279 (*C. A.* **25**, 415).

Artificial silk. N. V. HOLLANDSCHE KUNSTZIJDE INDUSTRIE. Fr. 693,411, April 5, 1930. Artificial silk of a dull luster is made by introducing into the spinning soln. terpenes or terpenic alcs. or mixts. thereof. An emulsifying agent such as sulfonated castor oil is also added.

Artificial silk. NOVASETA A. G. ARBON. Fr. 691,749, Mar. 11, 1930. Artificial

silk on leaving the spinning nozzles is given a preliminary coagulation in a coagulating bath and then caused to pass in a direction not deviating much from the vertical through at least one subsequent vessel traversed by a pptg. liquid to obtain a final coagulation.

Apparatus for drawing artificial silk in the moist state. FRANZ J. GAHLERT. Fr. 693,574, April 9, 1930.

Twisting and collecting artificial silk, etc. WM. P. DREAPER. U. S. 1,790,979, Feb. 3. Mech. features.

Artificial threads. MICHEL J. DASSONVILLE. Fr. 692,665, June 26, 1929. Cellulose threads having a structure and qualities comparable to those of natural wool are obtained by varying the section of the thread from the spinning nozzle by a correspond ing variation of the flow or of the pressure of the cellulose soln. about to be spun.

Artificial filaments. ALGEMEENE KUNSTZIJDE UNIE N. V. Ger. 514,400, Aug. 24, 1927. Artificial filaments of dull luster are prepd. from solns. of cellulose acetate or other cellulose ester or ether by dry-spinning these in a spinning cell into which water or water vapor is introduced. The spinning soln. may be anhyd. or not. Examples are given.

Luminous artificial filaments. HENRY A. GARDNER. U. S. 1,791,199, Feb. 3 Artificial filaments such as those formed from cellulose acetate or viscose contain a compd. of Ti such as the oxide and a small proportion of a radioactive substance, such as $RaBr_2$.

Removal of hydrogen sulfide from air of viscose-silk factories. N. V. NEDERLANDSCHE KUNSTZIJDE FABRIEK. Dutch 23,233, Dec. 15, 1930. The surplus alk. liquor from the prepn. of cellulose is used, dild. to 4%, for absorption of H_2S from the foul air; catalyzers, such as Ni, Cr and Mn salts (1%), are added for oxidation of the H_2S Cf. *C. A.* **24**, 4633

Fiber from wood. GEORGE A. RICHTER and MILTON O. SCHUR (to Brown Co.). U. S. 1,790,838, Feb. 3. Chipped wood such as jack pine is digested under pressure and with heating, in a saponaceous alk. liquor such as a NaOH soln. contg. 0.3-0.4% of soap. Cf. *C. A.* **25**, 414.

Wood pulp. GUSTAF HAGLUND (to Patentaktiebolaget Grondal-Ramen). U. S. 1,791,476, Feb. 3. Wood chips, before cooking with a liquor such as a sulfite soln., are preliminarily soaked in a cooking liquor produced in the usual manner without any addn. of waste liquors from previous cooking operations, and, after removal of part of the cooking liquor, the chips are cooked with a cooking liquor mixed with waste liquor from a previous cooking operation or with such liquor from a cooking app. still in action.

Cellulose pulp web. GEORGE A. RICHTER (to Brown Co.). U. S. 1,790,839, Feb. 3 A web which is highly absorptive of impregnating substances comprises gelatinized cellulose and loosely felted, substantially uncompacted fibers in unbeaten condition.

Cooking cellulose. ALB. E. NIELSEN. Norw. 46,601, June 17, 1929. The cooking is carried out by indirect steam heating with circulation of the liquor through an app. outside the digester. During the cooking process the liquor is subjected to a successive evapn. in the circulation app. in order to increase the heat value of the waste liquor, reduce the consumption of fuel and raw material and increase the output of pulp.

Pulp beater ("pulping engine"). S. MILNE. Brit. 335,671, July 26, 1929.

Apparatus for continuous beating and brushing of paper-making stock. THOMAS J. MULLEN. U. S. 1,790,830, Feb. 3. Structural features.

Washing paper-making pulp. OTTO MANTIUS. U. S. 1,790,714, Feb. 3. App and various details of app. and operations are described.

Paper. FRIEDRICH K. WICKEL. Ger. 515,186, Mar. 27, 1928. Impervious transparent paper is prepd. from sulfite cellulose paper by impregnating this, as completely as possible, with anhyd. glycerol, and then coating it on both sides with an aq. soln. of albumin, preferably egg albumin, to which addns. such as hardening agents may be made. A soft and non-adhesive product is obtained after drying. Cf. *C. A.* **24**, 1741.

Unbleached paper, cardboard, etc. VALDEMAR W. D'OBRY. U. S. 1,791,092, Feb. 3. A grass is moistened and steamed under pressure while preventing escape of substantially all the constituents of the grass, and the material is then mech. disintegrated for making paper, cardboard or the like. Cf. *C. A.* **24**, 1981.

Paper-making apparatus. DEE L. SHEAFOR (to Black-Clawson Co.). U. S. 1,791,384, Feb. 3. Structural features.

Paper-making apparatus. NILS A. JACOBSEN. U. S. 1,791,412, Feb. 3. A device is provided, actuated by the wt. of torn off paper, for automatically dividing the paper web on the wire cloth in 2 or more parallel strips in case tearing of the paper web should be started because part of the paper is carried along with the wire cloth about the couch roller.

Suction box for paper-making apparatus. EARL E. BERRY (to Beloit Iron Works). U. S. 1,790,852, Feb. 3. Suction boxes are made of comparatively thin-wall material composed of a Cr alloy such as "stainless steel" having a high modulus of elasticity and resistant to corrosion by the liquids with which it comes into contact.

Waterproofing paper. WM. H. RICHARDSON (to Richardson Co.). U. S. 1,791,040, Feb. 3. In making waterproof cartons, a blank is printed and sprayed with paraffin on the printed side, and afterward is calendered with calender rolls. App. is described.

Composition for waterproofing paper, millboard, papier maché articles, etc. DUNLOP RUBBER CO., LTD., D. F. TWISS and G. GORHAM. Brit. 335,559, June 25, 1929. A material suitable for treating *containers for food* consists of an aq. emulsion or dispersion of rubber, gutta-percha, balata or the like, in admixt. with an aq. dispersion of a mineral or vegetable wax or mixt. of waxes, *e. g.*, paraffin, in which the wax content may amount to 20–95% of the "dry rubber-wax content." The compn. may also be used for sealing the lids of the containers.

Dyeing paper and paper pulp. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 693,172, April 2, 1930. A unilaterally mono- or di-acylated diamine such as oleyldiethylethylenediamine is used as adjuvant in dyeing paper or paper pulp.

Recovery of paste from printed paper, and chiefly wood paste. LOUIS GRENAUDIER. U. S. 1,791,445, Feb. 3. Materials such as old newspapers are soaked in water and then treated with an alk. bath such as Na_2CO_3 to form an alk. soap with the fatty matter of the ink, and a substance such as NaCl is used which renders the soap insol. so that the ink-contg. soap rises to the top of the bath and does not mix with the paste in the bottom of the bath.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE AND C. G. STORM

Drying powder and explosive materials in vacuum. I. BODEWIG. *Chem. App.* **17**, 253–4, 279–80(1930).—B. reviews the difficulties encountered in drying powder and tells of improvements in the app. M. C. ROGERS

High brisance studies on explosive effect and chemical constitution. I. Tetranitromethane and its mixtures with toluene. ALFRED STETTBACHER. *Z. ges Schiess- Sprengstoffw.* **25**, 439–41(1930).—S. describes the prepn. of $C(NO_2)_4$ from $(CH_3CO)_2O$ and HNO_3 in lab. app. Because of the time required for the reaction (10–12 days) and poor yield (56%), the product has no industrial application. Its properties are described. When properly neutralized and dried, it is apparently quite stable. A mixt. of 100 parts $C(NO_2)_4$ and 15.66 parts $C_6H_5CH_3$ has a heat of explosion of 1701 Cal./kg. The sensitiveness of this mixt. is greater than that of nitroglycerin, and its brisance as indicated by Fe plate tests is even greater than that of gelatin-penthrinit (*C. A.* **24**, 6017; **25**, 818). C. G. STORM

High brisance studies. II. Mannitol hexanitrate (nitromannitol) and pentaerythritol tetranitrate (Penthrit). ALFRED STETTBACHER. *Z. ges. Schiess- Sprengstoffw.* **25**, 461–2(1930).—In comparative tests of nitromannitol and "Penthrit," alone and in mixts., S. again attributes the greater explosive strength of the "Penthrit" to its mol structure about a central C atom (*C. A.* **24**, 6017). Approx. 30 g. samples were detonated in heavy Fe crucibles on brass or Fe plates, these being preferred to Pb plates because of their greater hardness. Among other mixts. tested, one contg. nitromannitol 37.5%, nitroglycerin 56.2%, TNT 6.3% was compared with "Penthrit" 34%, nitroglycerin 51%, nitrocellulose 2.15%, NH_4NO_3 12.9%, both mixts. having an exact O-balance. The latter mixt. gave slightly superior results. A frozen mixt. of 60% "Penthrit" and 40% nitroglycerin (60/40 "Penthrinit") is claimed to have the highest rate of detonation of known explosives—9500 m./sec., as against 9000 m./sec. for frozen nitroglycerin. C. G. STORM

The preparation of nitrocellulose with maximum nitrogen content. F. LENZE AND E. RUBENS. *Z. ges. Schiess- Sprengstoffw.* **26**, 4(1931).—Nitrating expts. were made with cotton linters and mixts. of HNO_3 with H_2SO_4, SO_2 $(CH_3CO)_2O$, N_2O_5 and P_2O_5 in varying proportions. A max. N content of approx. 14% was obtained with a nitrating mixt. of HNO_3 and P_2O_5. The product was only slightly sol. in Et_2O-EtOH mixt. Further expts. are in progress. C. G. STORM

The properties of the nitroglycerin isomers. A. A. DSERSHKOVICH AND K. K. ANDREEV. *Z. ges. Schiess- Sprengstoffw.* **25**, 353–6, 400–3(1930).—The literature of the subject is reviewed. D. and A. compared liquid nitroglycerin (*A*) with the frozen labile

(*B*) and stable (*C*) forms, as regards brisance and rate of detonation. The Pb block test method of Hess showed (*C*) to have much greater brisance than either (*A*) or (*B*), and also to be more sensitive to detonation. The same relation was confirmed by the Kast method (compression of Cu cylinders), although this method gave discordant results. Rate of detonation tests were made by the Dautriche method in glass tubes 22 mm. inside diam. with 2 mm. walls; picric acid detonating fuse having a rate of 7000 m./sec. was used. (*C*) gave the remarkably high rate of 9150 m./sec. (av. of 3); (*A*) gave 1165 m./sec. (*B*) failed to detonate completely with No. 8 detonators, but gave a rate of 9100 m./sec. when a booster of 20 g. tetryl was used. Similarly, (*A*) gave a rate of 8750 m./sec. when a booster of 10–15 g. (*C*) was used. Contrary to the rate of detonation results (*B*) gave the highest Trauzl block test (560 cc.); (*A*), 518 cc.; (*C*), 390 cc. In this test the insensitiveness of (*B*) was probably overcome by the confinement afforded by the sand stemming. No appreciable difference was found as regards sensitiveness to impact. When properly protected from contamination, (*B*) remained unchanged for periods as long as 70 days. The linear conversion velocity and crystn. velocity of the isomers were detd. It is suggested that the loss of sensitiveness of gelatin dynamites during storage is the result of gradual conversion of (*A*) to (*B*).
C. G. STORM

Researches on coal-mining explosives at the Safety in Mines Research Station, Buxton. W. PAYMAN. *Trans. Inst. Mining Eng.* **80**, 11–23(1930–1931).—Tests are made to det. the safety of explosives in dusty and gassy coal mines. These tests include the number of cartridges in a shot-hole, the position of the detonator, the character of the stemming, the safety in the presence of coal dust and of methane. Ignitions of gas have been obtained with as little as 2 oz. of a permitted explosive with no stemming, but 1 in. of noncombustible stemming will prevent ignition of gas with 28 oz. of a similar explosive. The presence of an inhibitor to prevent ignition of gas by explosives has been considered but this method has not been found practical. Expts. on the effect of compression of gas have indicated that, up to at least 11 atm., as the pressure of the air and methane is increased the ignition point is lowered. When the pressure is reduced the ignition point of methane and air is reduced even more rapidly than under increased pressure. A max. temp. is reached in the case of methane under about $^1/_3$ of an atm. The greatest amt. of work is done when a detonator is placed in the cartridge next to the stemming and pointing inward.
C. W. OWINGS

Explosive limits of fire damp. E. KIRST. *Glückauf* **67**, 50–7(1931).—Results of recent investigations were discussed.
J. D. DAVIS

A review of some recent dust explosions. D. J. PRICE AND H. R. BROWN. *Quart. Natl. Fire Protect. Assoc.* **24**, 305–29(1930).—A comprehensive report is given on dust explosions at Western Maryland Grain Elevator, Hogan Mill Feed Co., E. F. Carlston Elevator Co., Tobacco Byproducts and Chem. Corp. and Staley Manufacturing Co. All these dust explosions occurred during August and September, 1930, resulting in a gross loss of approx. $500,000. Analysis of all that is known of the causes further emphasizes the necessity of cleanliness in industries producing flammable dusts, importance of controlling equipment design to minimize the likelihood of stirring up dusts or igniting them, and the value of inert gases as a method of preventing dust explosions in grinding equipment.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Standard colors and fewer dyes would benefit textile industry. ALOIS MAERZ. *Textile World* **79**, 428-30(1931). RUBY K. WORNER

Color measuring and color standards. M. J. SCHOEN. *Chem. Weekblad* **28**, 105–6 (1931). G. G.

Photoelectric cell has definite place in color measurement. WALTER M. SCOTT. *Textile World* **79**, 886–9(1931).—A résumé is given of the accomplishments to date along the line of color measurements, together with a warning to textile manufacturers "that they must not look for an immediate millenium in this field." The applicability, limitations and future possibilities of the photoelec. cell for color measurement are discussed. The following color analyzers that use this device are briefly described: the T[illegible] C. B. Photocolorimeter, designed by Toussaint; the photoelec spectrophotometer developed by the American Photoelec. Corp. marketed by Eimer & Amend; the portable recording and indicating color analyzer developed by P. J. Mulder and J. Rasek, marketed by the Burgess-Parr Co.; the Colorscope, developed by H. H. Sheldon, New York Univ.; and the recording photoelec. color analyzer developed by A. C. Hardy, manufactured by General Elec. Co. The fallacies of the following claims are pointed out: that the photoelectric cell introduces a distinctly new method of color measurement; that it entirely eliminates the human eye and therefore greatly increases the accuracy of the measurement by doing away with the variable human factor; and that photoelec. instruments are so simple to operate that no previous specialized training is necessary. R. K. W.

Relation between structure and affinity of dyes for plant fibers. MIECZYSLAW DOMINIKIEWICZ. *Przemysl Chem.* **14**, 289–98(1930).—See *C. A.* **24**, 5501. A. C. Z.

The vat colors from a cotton piece dyers' point of view. GEO. H. HARRIS. *Dyer, Calico Printer* **64**, 643-4(1930).—A brief discussion based on practical experience is given of the difficulties involved in the use of vat colors. The selection of a suitable dyestuff, and the importance of such factors as the quality of the water, the temp of the dye bath, the method of handling the goods in running them through the dye bath, etc, are considered. RUBY K. WORNER

Pectographic studies of solutions of dyestuffs. PAUL BARY. *Rev. gén. colloïdes* **8**, 62–8(1930); cf. *C. A.* **24**, 3417. The similarly constituted compds. parafuchsin and fuchsin AB in aq. solns. give the same sort of pectographs in dil. and concd. soln., with crystn. being retarded in dil. soln. Methyl violet does not give crystals. Safranine T gives crystals at all concns., while safranine MN gives amorphous bands but yields crystals at 0.025% concn. Hence, in safranines, dilu aids crystn. and impedes it in the triphenylmethane derivs. The choice of solvent modifies completely the pectographs obtained in almost all cases. Picric acid in acetone gives clear unique crystals while in alc. it gives a gel impregnated with crystals. Safranine MN, which in water gives an unstable gel and crystals, in acetone yields fine lines as also do safranine T, methyl violet, parafuchsin, crystal violet and Induline scarlet. Ultramicroscopic examns. of these solns. show that all those which give a pectograph of fine parallel lines contain visible granules while those which give a gel deposit are optically void. F. W. L.

Action of nitrous acid on animal fibers, and reactions of the products formed with azo components. M. J. VAN TUSSENBROEK. *Chem. Weekblad* **28**, 62–5(1931).—The question is reviewed whether HNO_2 forms reactive diazonium compds. with amino acids of the fiber, or whether it is merely absorbed, leading, on development, to nitrosophenols and their dye derivs. Formation of $HOC_6H_4N_2NO_2$ from PhOH and N_2O_3 in excess (Morel and Sisley, *C. A.* **22**, 4515) was confirmed in this particular instance only. When N_2O_3 was conducted into an Et_2O soln. of *p*-cresol and tyrosine, $HO(O_2N)_2C_6H_2Me$ was formed, but no diazo compd. Light fastness of dyes developed on the fiber is very good, especially upon afterchroming. Shades are decidedly changed (deepened) and acid and alkali fastness improved by chroming. Diazotized fibers show light sensitivity. Photographs may be printed out on silk. K. H. ENGEL

Rapid identification of dyes on fibers. RAYMOND LEVÉ. *Tiba* **9**, 11–7(1931).—A scheme of analysis is presented for the rapid identification of the class of dye used on a given sample. The various tests (treatment with HClO, boiling with Na_2CO_3, reduction with $SnCl_2$ and with alk. hyposulfite) are carried out by adding the reagents to the dyed fibers in test tubes. A. PAPINEAU-COUTURE

The dyeing of cotton warp during sizing. A. POUZET. *Tiba* **8**, 1447–9(1930).—The dyeing of cotton warp in the sizing bath and before sizing is described and a no. of formulas for each process are given. A. PAPINEAU-COUTURE

Chemical finishing treatments of cotton. C. THIBAUD. *Tiba* **8**, 1457–63(1930); **9**, 35–41(1931).—The treatments, other than mercerization and bleaching, which effect a considerable modification in the phys. aspect of cotton are described. A. P.-C.

Dyeing and finishing cotton corduroys. L. MACKIRDY. *Textile Recorder* **48**, No. 575, 57–9(1931).—A detailed description is given of the processing of this type of fabric from the time it comes from the loom "in the grey" to the final folding and boxing of the finished article. RUBY K. WORNER

Continuous bleaching challenges the chemist. WINN W. CHASE. *Textile World* **79**, 636–7(1931).—The need of chem. developments to keep pace with the mech. improvements is stressed. RUBY K. WORNER

Practical suggestions for better handling of acetate yarns. STEWART H. GILSTON. *Textile World* **79**, 431–3(1931).—Suggestions are given for modifications and adjustments of the machinery used in winding, twisting and tinting cellulose acetate yarn. RUBY K. WORNER

Preparation of fabrics made of, or containing, acetate rayon, prior to dyeing. J. CALLADINE. *Russa* **5**, 1871, 1873(1930). A. PAPINEAU-COUTURE

Dyeing of acetate rayon. HERBERT BRANDENBURGER. *Kunstseide* **12**, 267–72 (1930); cf. *C. A.* **25**, 209.—Photochemical decomposition of the dyes. The fading of dyes on acetate-rayon fabrics is discussed in the light of oxidation, reduction and enzyme theories. Most of the cases discussed are explained on the basis of oxidation. According to this theory the dyestuff forms a peroxide which oxidizes the constituents of the dye. The dyeing of cellulose acetate is viewed as a soln. process and not as an adsorption process. The dye is present in a more finely divided state than on cotton textiles and therefore a greater surface of the dye is exposed to oxidation. On this basis is explained the poor fastness of basic dyes and acid (wool) dyes on acetate rayon. The fastness of various diazo colors and its relation to their constitution are discussed. *Ibid* 305–10.—A retrospect and an outlook in the future of acetate rayon developments with regard to the dyeing of this type of rayon and its mixts. with cotton, viscose rayon, wool and silk. FREDERICK C. HAHN

Dyeing acetate rayon black. JEAN PAUL SISLEY. *Tiba* **9**, 17–23(1931).—A review of the various dyes and processes which have been proposed. A. PAPINEAU-COUTURE

Practical viscose dyeing. HANS ENGEL. *Kunstseide* **12**, 290–2(1930); *Jentgen's Rayon Review* **2**, 255–6(1930).—Blotchily dyed viscose rayon is as a rule caused by unsuitable preliminary washing and improper handling during dyeing, and, less frequently, to the choice of dyestuff. Streakiness in the dyeing is due to abnormal viscose. The foregoing difficulty may be obviated by the use of dyes of the Rigan type, or mixts. thereof with other direct dyes which are known to equalize well. F. C. H.

The structure of rayon in relation to aniline-black dyeing. A. J. HALL. *Silk J.* **7**, No. 77, 37–8, No. 78, 33, 41(1930); cf. *C. A.* **24**, 6021.—Because of the greater absorbent properties of the regenerated rayons they give a better black than cotton. Acetate rayon shows a selective absorbency for basic compds., and will not absorb salts. Aniline and other amines are absorbed but the oxidant ($NaClO_3$) is not. It is suggested that acetate rayons might be treated with aniline first and then oxidized in a fresh bath. At present aniline black has not been satisfactorily dyed on acetate rayons. A. R. MACORMAC

Preparation, dyeing and finishing of rayon crepes. A. CRISPE. *Russa* **5**, 59–63 (1931). A. PAPINEAU-COUTURE

Printing of fast-color rayon crepes requires careful attention to details. HAROLD B. STURTEVANT. *Textile World* **79**, 338–4(1931). RUBY K. WORNER

Sizing and finishing of rayon. W. A. DYES. *Kunstseide* **12**, 313–5, 340–2(1930); cf. *C. A.* **24**, 1986.—A discussion of the prepn., testing and required properties of starch pastes for the sizing and finishing of rayon. FREDERICK C. HAHN

The coloration of silk stockings. S. R. TROTMAN. *Dyer, Calico Printer* **65**, 23–4 (1931); cf. *C. A.* **24**, 1985.—The various processes are described with particular emphasis on the difficulties involved. The water used, the preliminary soaking, the app. used for dyeing, the degumming process, the dyeing of pure silk and silk-cotton stockings, the selection of suitable dyestuffs for each type, etc., are discussed. RUBY K. WORNER

Hosiery redyeing made easier. HERBERT C. ROBERTS. *Textile World* **79**, 345 (1931).—Before stripping, a preliminary bath composed of 1–3% soda ash and $1^1/_2$–$1^3/_4$% sol. pine oil is recommended. The advantages of the use of the sol. pine oil are: It penetrates and opens up the fibers without injurying them. It removes part of the color, but does not start the resist colors in the picot edge or clock. It reduces the amt. of hyposulfite or sulfoxylate needed. It reduces the stripping time, thereby reducing also the danger of mech. injury to the goods. RUBY K. WORNER

The preparation of tussah silk and schappe silk prior to dyeing. J. BRACONNOT. *Russa* **5**, 1867–71, 2043–7(1930); **6**, 41–5(1931).—A review. A. P.-C.

The printing of wool and silk using the Neolan colors. VERNON D. FREEDLAND. *Dyer, Calico Printer* **64**, 646–7(1930).—The Neolan dyes used for printing are divided into those which require the addn. of Cr acetate to the printing paste and those which do not require it. Recipes are given for each type. A list of the solubilities of these dyestuffs in H_2O at 212°F. is also given. RUBY K. WORNER

Plate printing on silk. J. CLAROU. *Russa* **5**, 1705–9(1930).—Practical operating hints, with a no. of formulas. A. PAPINEAU-COUTURE

The dyeing and finishing of union wool-silk goods. L. BONNET. *Russa* **5**, 2047–57 (1930).—This is a general description, dealing more particularly with the various types of machines available for the handling of the goods. A. PAPINEAU-COUTURE

Dyeing wool with indigo in fermentation vats. E. DUTOIT. *Tiba* **8**, 1309–19 (1930).—The principles and technic of the process are described. A. P.-C.

The treatment of lace curtains. C. L. FISHWICK. *Tiba* **8**, 1435–41(1930).—Methods of bleaching, dyeing and finishing of lace curtains, at present in use in various European countries, are described. A. PAPINEAU-COUTURE

Dyeing and finishing curl cloths. DOUGLAS KERMODE. *Dyer, Calico Printer* **65**, 139–40(1931); cf. *C. A.* **24**, 6022.—Curl cloths consist of a worsted or worsted-mohair pile in loop form, knitted into a cotton backing. As a rule its manuf. is a work for specialists. Dyestuffs which have been found suitable for this type of fabric are listed and methods of applying them are described. RUBY K. WORNER

The dyeing of wool-felt and hair-felt hats. E. DUTOIT. *Tiba* **8**, 1441–7(1930).—Practical operating hints with a no. of formulas are given. A. PAPINEAU-COUTURE

Dyeing vegetable-ivory buttons. KARL HAHN. *Dyer, Calico Printer* **64**, 399–400 (1931).—See *C. A.* **24**, 5502. RUBY K. WORNER

Bleaching and dyeing leaves and grasses. F. GROVE-PALMER. *Dyer, Calico Printer* **64**, 707–8(1930); cf. *C. A.* **25**, 561.—The basic dyes are generally used for these materials because of their brightness, cheapness and high tinctorial power. Cellulose enamels in various colors may be sprayed on with an air pistol. Metal leaves can be obtained by spraying on bronze powder in a clear cellulose medium, or better still by electroplating with metals. RUBY K. WORNER

Kaoliang starch as a finishing material for textiles. JUSABURO KAWAMATA. *Abstract from Rept. Central Lab. S. Manchuria Railway Co.* **1929**, 27–9.—In respect to its value as a sizing material kaoliang starch occupies a position between wheat starch and corn starch. V. F. HARRINGTON

Noteworthy machinery development of recent years marches unretarded through 1930 into 1931. EDWIN D. FOWLE. *Textile World* **79**, 604–7(1931).—A review of new machinery developed for bleaching, dyeing and finishing. RUBY K. WORNER

A new use for textiles. GEO. RICE. *Dyer, Calico Printer* **65**, 28–9(1931).—Cotton stationery is described with particular reference to the processes used for stiffening, coating, weighting and glossing the fabric. The requirements of this material are that its stiffness shall be such that it can be written upon with a pen or printed upon with a typewriter; that the interstices shall be filled, and the finish smooth, so that the impression of the pen or the typewriter will be even; that the handle shall be satisfactory; that the writing shall be retained even when wet; and that the fabric must permit erasures. RUBY K. WORNER

Washing cotton and linen. YNGVE DALSTRÖM. *Svensk Kem. Tids.* **42**, 263–77 (1930).—A crit. review is given of the conflicting laundry technology literature. A. R. ROSE

Future textile-laboratory practice. GEO. B. HAVEN. *Am. Dyestuff Reptr.* **19**, 757–61(1930); *Textile World* **78**, 3028–30(1930); **79**, 42–4(1931); *Melliand* **2**, 1319–28 (1931).—New avenues are suggested for directing the future work of the Textiles Committee of the Am. Soc. for Testing Materials. Illustrated descriptions are given of app. for measuring yarn balance, corkscrew in yarns, crimp and yarn slippage, all of which are properties of the yarn, and for measuring porosity, absorbing power for liquids, bursting strength, precise thickness, abrasion, heat flow and resilience of fabrics. R. K. W.

Influence of laundering and exposure to light upon some washable silks. MARION GRIFFITH. Ohio Agr. Expt. Sta., *Bimonthly Bull.* **147**, 179–81(1930).—Only pure dye branded silks were used. All 12 samples showed a very decided fading upon exposure to light and during the laundering process. Blue and green colors faded most, while peach and yellow were least affected by light exposure. The highest-priced silk contained less than $^1/_3$ the amt. of finishing materials present in the least expensive silk. The breaking strength varied from 31–69% of the original when exposed 48 hrs. to light. The de

crease in strength resulting from 15 launderings varied from 15–17%. The silks lost 25–42% of their original elasticity as a result of exposure to light for 48 hrs.. The expts. are being continued along chem. lines. C. R. FELLERS

A cloth-wear testing machine. J. A. MATTHEW. *J. Textile Inst.* **21**, 546–60T (1930).—The design of machines for testing cloth wear is discussed and a new machine is described. Its principle is that a sample under a definite tension is rubbed with a Carborundum surface. The no. of rubs necessary to produce fracture is taken as a measure of the resistance of the cloth to wear. Results are given to show the effect of varying the rubbing conditions for a cloth and also to show the comparative resistance to wear of a no. of cloths under fixed rubbing conditions It is shown that wear tests and tensile strength tests bear little relation to each other. RUBY K. WORNER

Relation of cotton to synthetic fibers. C. E. MULLIN. *Jentgen's Rayon Review* **2**, 231–8(1930).—See *C. A.* **24**, 5483. FREDERICK C. HAHN

Fiber cross-section. H. L. BARTHELEMY. *Kunstseide* **12**, 316–7(1930).—An improved method of making rayon cross-sections is described. A slit is made lengthwise in a small cork to a depth $^2/_3$ of the diam. A single thread of rayon is placed in the slit parallel to the axis of the cork and then disks are cut therefrom with a razor. This method is an advantage over the Herzog method in that the individual filaments can be distinguished and counted FREDERICK C. HAHN

Fiber cross-section of acetate rayon. H. STADLINGER. *Jentgen's Rayon Review* **2**, 240–3(1930); *Kunstseide* **12**, 310–3(1930).—The two general types of acetate rayon cross-sections, "ribbon-like" (I) and "cloverleaf" (II) are discussed, and microphotographs are given of the cross-sections of various com. acetate rayons. Earlier acetate rayons were of the type I but present-day rayons are of type II. Type II are superior as regard to lower gloss and higher wet and dry strengths. FREDERICK C. HAHN

Physicochemical studies on the structure of wool hair after treatment with alkali, acids and chlorine. ERNST TANZER. *Wiss. Arch. Landw., Abt. B, Tierernähr. Tierzucht* **4**, 297–346(1930).—Wool from several breeds of sheep was treated with HCl, H_2SO_4, HNO_3, AcOH, Cl water and chloral hydrate; the wool was then investigated as to histological changes, change in wt., fineness, flattening, hygroscopic properties, tensile strength, elasticity, polarization, reaction with methylene blue, biuret test, reaction with Millon's reagent and Allwördens reaction. Many references are appended. W. GORDON ROSE

Rotenone as a moth-proofing agent. E. A. BACK, R. T. COTTON AND R. C. ROARK. *J. Econ. Entomol.* **23**, 1014(1930).—Rotenone, the insecticidal constituent of derris root, cubé root and some other tropical plants is effective as a moth-proofing agent. From 1 to 2% of rotenone is dissolved in acetone and the soln. is used to impregnate woolen goods. The impregnated goods appears to be highly resistant to attack of the clothes moth, *Tineola biselliella*, and of the beetles, *Anthrenus vorax* and *Attagenus piceus*. Acetone solns. contg. as low as 0.05% rotenone gave excellent protection from these insects. The rotenone treatment appears to be equal to that of other propietary moth-proofing solns. now on the market. Application for a public service patent has been filed. C. H. RICHARDSON

Note on a little-known fireproofing process. E. DUTOIT. *Tiba* **9**, 33(1931).—Perkin's method consists in impregnating flannel with a 26° Bé. Na stannate soln., draining, drying between heated Cu rolls, treating with a 10° Bé. $(NH_4)_2SO_4$ soln. to ppt. $Sn(OH)_4$, draining, drying, washing and drying again. The resultant fireproofing is permanent, as the SnO_2 is combined with the fiber; it increases the mech. strength of the fabric and its resistance to washing and ironing, and moreover it acts as mordant if it is to be dyed. A. PAPINEAU-COUTURE

Condensation products from aryldithioglycolic acids [dyes] (GEBAUER-FÜLNEGG JARSCH) **10.** Heteropolar C compounds. XII. New dyestuffs of the aniline blue series and perchlorates of several important triphenylmethane dyes (DILTHEY, DINKLAGE) **10.** β-Hydroxy-α-picoline azo dye (Brit. pat. 335,818) **10.** Leuco indigo (Fr. pat. 693,469) **10.** Triazine derivatives [intermediate] (Brit 335,783) **10.**

Dyes. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES DE PRODUITS CHIM. DU NORD RÉUNIES (ÉTABLISSEMENTS KUHLMANN). Fr. 692,927, June 28, 1929. Anthraquinone derivs. which dye cellulose acetate silk are prepd. by the reaction of sulfonic acids of aminohydroxyanthraquinones such as diaminoanthrarufin and diaminochrysazine, their salts or reduction products, with either an aldehyde or its substitutes in the presence of hyposulfite, or hyposulfite compds. of aldehydes previ-

ously formed in the presence of an excess of hyposulfite or sulfoxylates of aldehydes. Thus, Na diaminoanthrarufin-2,6-disulfonate is dissolved in water and BzH and $Na_2S_2O_4$ are added and the mixt. is heated. The product dyes cellulose acetate blue. Several other examples are given.

Dyes. I. G. FARBENIND. A.-G. Fr. 693,474, April 7, 1930. Dyes of the anthraquinone series are made by the reaction of α-aminoanthrimidcarbazoles or their substitution products with anthraquinone-*o*-halocarboxylic acids or their derivs. or substitution products and transforming the reaction products into the corresponding acridones by the known methods. Thus, 4-amino-1,1′-anthrimidcarbazole (by sapon. of 4-benzylamino-1,1′-anthrimidcarbazole) is heated with anthraquinone-2-bromo-1-carboxylic acid in the presence of AcOK, MgO and $(AcO)_2Cu$. The product dyes cotton from the vat in olive-green shades. Other examples and formulas of the products obtained are given.

Dyes. I. G. FARBENIND. A.-G. Fr. 693,169, April 2, 1930. *N* condensation products which dye cotton from the vat are prepd. by condensing aminoanthraquinonecarboxylic acids, the COOH groups of which are so transformed that they do not form salts, with negatively substituted polynuclear org. compds. Thus, dibromo-3,4,8,9-dibenzopyrene-5,10-quinone is boiled in $C_{10}H_8$ with NaOAc, CuO and the Et ester of 1-aminoanthraquinone-2-carboxylic acid until practically all the Br is removed. The product dyes cotton in violet-red shades from the vat. Several other examples are given.

Dyes. I. G. FARBENIND. A.-G. (Paul Ochwat, inventor). Ger. 515,331, May 2, 1929. The dyes obtainable from anthrimides by acid or alk. condensation are halogenated, and the products are caused to react with N compds. contg. at least one exchangeable H atom. Products giving deeper shades than the initial dyes are so obtained. Thus, the dibromo deriv. of a dye prepd. as described in Ger. 507,340 (*C. A.* **25**, 599) may be boiled for 2 days in $C_{10}H_8$ with 1-aminoanthraquinone in the presence of Na_2CO_3, NaOAc and CuCl. Other examples are given also.

Dyes. I. G. FARBENIND. A.-G. (Paul Nawiasky, inventor). Ger. 515,096, July 17, 1928. Addn. to 498,292. The method of purifying *N*-dihydro-1,2,2′,1′-anthraquinonazine described in Ger. 498,292 (*C. A.* **24**, 3907), is now applied to the dye obtained by treating the above compd. with H_2SO_4 of low-water content, preferably in the presence of H_3BO_3. An example is given. Cf. *C. A.* **25**, 599.

Azo dyes. ERNEST F. GRETHER (to Dow Chemical Co.). U. S. 1,790,807, Feb. 3. Azo dyes which give various red shades are formed from the tetrazo deriv. of a diaminodiaryl ether such as diaminodiphenyl ether coupled with an arylide of 2,3-hydroxynaphthoic acid such as 2,3-hydroxynaphthanilide.

Azo dyes. GUILLAUME DE MONTMOLLIN (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,791,444, Feb. 3. By coupling arylides of 2,3-hydroxynaphthoic acid such as the arylide derived from *o*-aminodiphenyl ether with diazo compds. such as those derived from 4-chloro-2-aminodiphenyl ether, *o*-aminodiphenyl ether, the corresponding cresylchlorophenyl or chlorocresyl ether or the benzyl ethers of *o*-aminophenols or *o*-aminocresols, fast red dyes are produced, which may be formed on a suitable substratum and employed for making *red varnishes*. Examples and details of procedure are given.

Azo dyes. MAX SCHMID and FRITZ STRAUB (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,791,432, Feb. 3. Azo dyes suitable for conversion into metal derivs. such as those of Cr or of Cu are obtained by coupling a diazo-compd. contg. an OH group in *o*-position to the diazo group (such as the diazo deriv. of 4-chloro-2-aminophenol-6-sulfonic acid or 1-diazo-2-naphthol-4-sulfonic acid) with pyrazolone derivs. such as 5-pyrazolone-3-carboxylic acid or its Me or Et ester. Examples are given of dyes the Cr compds. of which produce violet or red dyeings.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 335,555, June 21, 1929. Dyes insol. in water are formed in substance, on the fiber or on a substratum by coupling the diazo compd. of an amine of the general formula aryl-NH.R′.X.R″.NH_2 (in which R′ and R″ are aromatic nuclei which may be substituted or unsubstituted and X represents either a direct linkage or an —N:N— group, or in which —R′—X—R″—stands for a condensed aromatic system) with an arylide of 2,3-hydroxynaphthoic acid. By use of 2 mol. proportions of nitrite, nitrosodiazo compds. are obtained and the corresponding nitrosoazo dyes may be treated in substance or on the fiber with a reducing or saponifying agent to remove the nitroso group. Several examples are given. Cf. *C. A.* **25**, 1092.

Azo dyes. I. G. FARBENIND. A.-G. (Rudolf Heil, inventor). Ger. 515,230, Sept. 9, 1928. Brown azo dyes insol. in water are prepd. by coupling the diazo compds. from 2-amino-*N*-alkylpyrazoleanthrones, or 2-amino-*N*-aralkylpyrazoleanthrones, with arylides of 2,3-hydroxynaphthoic acid. An example is given.

Azo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 692,694, March 3, 1930. See Brit. 331,839 (*C. A.* **25**, 213).

Monoazo dyes and amines. BRITISH RESEARCH ASSOCIATION FOR THE WOOLEN & WORSTED INDUSTRIES and A. T. KING. Brit. 335,646, July 6, 1929. Monoazo dyes and amines are produced simultaneously by the reduction of disazo dyes of the type X.N:N.Y.N:N.$C_{10}H_6$(OH) in which X and Y represent aromatic residues such as those of benzene, naphthalene, diphenyl, diphenyl sulfide or other grouping, the reduction being effected with alkali metal bisulfite (with intermediate formation of disazosulfites). The disazosulfites may be treated with alkali metal hyposulfite to produce the amine or aminoazo compd. Several examples are given.

Disazo dyes. I. G. FARBENIND. A.-G. Brit. 335,705, Oct. 4, 1928. A disazo dye giving vivid greenish yellow dyeings on wool, fast to fulling and to light, is formed by coupling tetrazotized 4,4′-diamino-3,3′-dichloro-5,5′-dimethyltriphenylmethane with 1-(2′-chloro-5′-sulfo)phenyl-3-methyl-5-pyrazolone The 4,4′-diamino 3,3′-dichloro-5,5′-dimethyltriphenylmethane is made by condensing BzH with 3-chloro-2-toluidine Mention is also made of the production of some other similar dyes. Cf *C. A.* **24**, 2304

Disazo dyes. I. G. FARBENIND. A.-G. (Karl Dobmaier, inventor) Ger. 515,231, Aug. 21, 1927. Disazo dyes giving yellow shades on cotton are prepd by coupling the diazo compds. from nitrobenzoylated diamines or their derivs. with suitable components free from NH_2 groups, reducing the NO_2 group of the monoazo dyes so obtained, diazotizing, and coupling with pyrazolone derivs contg diazotizable NH_2 groups, or with compds. of the C_6H_6 or $C_{10}H_8$ series in which a diazotizable NH_2 group is present in a "heteronuclear" side chain. Suitable components for the first coupling are phenols and their ethers and carboxylic acids, acetoacetanilide, and phenyl methyl pyrazolone For the second coupling, *m*-aminobenzoyl-2,5,7-aminonaphtholsulfonic acid is specified, *inter alia*. The reduced monoazo dyes may be condensed with nitrobenzoyl chloride or its derivs., reduced again, and diazotized before finally coupling as above. Other modifications are described also. Examples are given

Disazo and trisazo dyes and their metal compounds. SOC. ANON. POUR L'IND. CHIM. À BÂLE, F. STRAUB and W. ANDERAU Brit 335,523, April 23, 1929. Disazo and trisazo dyes obtainable by coupling with the monoazo dye from 2-amino-5-naphthol-7-sulfonic acid (2 mols. coupled acid) either 1 mol proportion of an *o*-hydroxydiazo compd. or 2 mol. proportions of an *o*-carboxy diazo compd , or one mol proportion each of an *o*-hydroxydiazo compd. and a diazo compd contg no *o*-hydroxyazo group (excluding in this case *o*-hodroxycarboxy-group-contg. diazo compds) are treated (at any stage) with chroming or other metallizing compds. such as compds. of Mn, Fe, Co or Ni Various examples are given for producing dyes of different colors.

Trisazo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 693,585, April 9, 1930. Trisazo dyes, contg. at least 2 COOH or 2 SO_3H groups or one of each and suitable for dyeing regenerated cellulose, are obtained by coupling tetrazotized 3-aminobenzene-1′-azo-4′-aminonaphthalene or a substitution product thereof with one mol. proportion of a phenol naphthol or a carboxylic or sulfonic acid thereof and with one mol. proportion of the same or another component other than a naphtholarylketone or an arylide of 2,3-hydroxynaphthoic acid. The same products are obtainable by coupling diazotized 3-nitrobenzene-1′-azo-4′-aminonaphthalene or a substitution product thereof with a phenol, naphthol or a carboxylic or sulfonic acid thereof, reducing, diazotizing and coupling with a suitable component Several examples are given.

***o*-Carboxyazo dyes.** I. G. FARBENIND. A.-G. Fr. 693,024, Mar. 29, 1930. *o*-Carboxyazo dyes dyeing substantively and contg Cu are made by the reaction of agents liberating Cu on dyestuffs obtained by coupling tetrazotized 4,4′-diaminodiphenyl-3,3′-dicarboxylic acid with 2 identical or different mols. of arylamino- or aroylaminonaphtholsulfonic acids which contain in the aryl or aroyl group groups which render the compd. sol. in water. Several examples are given

Vat dyes. I. G. FARBENIND. A.-G. (Arthur Wolfram and Emil Hausdörfer, inventors). Ger. 514,432, Dec. 31, 1927. See Brit. 303,375 (*C. A.* **23**, 4579).

Vat dyes. I. G. FARBENIND. A.-G. (Paul Nawiasky and Alfred Ehrhardt, inventors). Ger. 514,433, July 20, 1929. Green vat dyes are prepd. by halogenating dimethoxydibenzanthrone in an inert org. solvent in the presence of a catalyst, *e. g.*, $FeCl_3$. Examples are given.

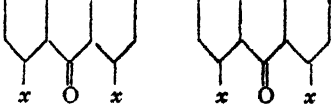
Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 515,328, Mar. 31, 1929. Addn. to 499,169 (*C. A.* **24**, 4168) and 510,600 (*C. A.* **25**, 1094). Violet to green-blue vat dyes are prepd. by treating dibenzanthrone or isodibenzanthrone or their derivs. with Br or other brominating agent in an acid medium in the presence of a metal or a metal compd. as a catalyst. Hg, Mn and Sb are suitable

catalysts, and when using these the use of $HClSO_3$ as the acid medium does not give rise to products contg. Cl. The products are fast to light and atm. influences. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Robert Berliner, inventor). Ger. 515,329, July 5, 1928. See Brit. 314,899 (*C. A.* **24**, 1520).

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 515,330, Dec. 30, 1928. Addn. to 513,228 (*C. A.* **25**, 1396). New vat dyes giving varied shades are prepd. by condensing neg. substituted dibenzanthrones or isodibenzanthrones with amides or imides of mononuclear carboxylic acids. The condensation may be effected in a high-boiling solvent in the presence of a catalyst and an acid-binding substance. The products may be sapond. by the usual methods to yield mono- or polyamino compds of the dibenzanthrone or isodibenzanthrone series. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 692,869, Mar. 28, 1930. Halogenated benzanthronepyrazoleanthrones, which dye textile fibers in valuable blue shades, are prepd. by treating benzanthronepyrazoleanthrone, its derivs. of isomers, preferably in the presence of catalysts, with halogens or substances capable of liberating halogens in the presence of diluents or solvents. Several examples are given.



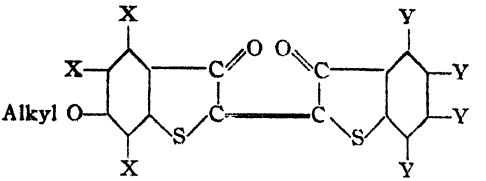
Vat dyes. I. G. FARBENIND. A.-G. Fr. 693,042, Mar. 29, 1930. Stable leuco vat dye prepns. forming by soln. in water a vat ready to be used for dyeing, are prepd. by mixing with a protective colloid, a wetting agent and a stabilizer, the leuco compds. of vat dyes of the anthraquinone and thioindigo series which are capable of dyeing from a "cold vat" of hyposulfite. The mixt. is dried and the dry powders ground with a caustic alkali and a reducing agent. Thus, the leuco compd. may be mixed with molasses, an alkylnaphthalenesulfonic acid, hydroquinone, caustic alkali and $Na_2S_2O_4$.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 693,107, April 1, 1930. Vat dyes contg. one or more halogens are prepd. by treating isodibenzanthrone or its derivs., or derivs. of dibenzanthrone, with anhyd. metallic halides capable of yielding halogens. If necessary other halogenation agents, substances lowering the m. p., appropriate catalysts, solvents or diluent are added. The halides of Fe, Al, Sb and Hg are suitable for the chlorination, and alkali and alk. earth salts may be used for lowering the m. p.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 693,410, April 5, 1930. Vat dyes are prepd. by heating 2-mercapto-1-methylanthraquinone or 3-mercapto-2-methylanthraquinone or their derivs. with S or by heating 2-halo-1-methylanthraquinone or 3-halo-2 methylanthraquinone or their derivs. with S and substances producing or facilitating the substitution of halogens by S. Several examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 693,817, April 12, 1930. Vat dyes are obtained by treating the anthraquinonyl-4'-amino-1,2-benzanthraquinones with condensing agents. Thus, α-anthraquinonyl-4'-amino-1,2-benzanthraquinone when heated with moderately dil. H_2SO_4 or with a mixt. of NaCl and $AlCl_3$ gives a product which dyes pure yellow from the vat. The same initial material treated with $AlCl_3$ in the presence of a tertiary base such as pyridine gives a greenish blue from the vat. Several other examples are given.

Vat dyes (anthraquinonylcarbazoles). FRITZ BAUMANN (to General Aniline Works). U. S. 1,791,184, Feb. 3. Vat dyes of the general formula:



wherein at least one *x* stands for an anthraquinonylimino residue being attached to the nucleus by only one linkage in the position *x*, and the other *x*'s stand for substituents of the group consisting of H and any univalent substituent and wherein all nuclei may be further substituted, generally red to grayish powders, insol. in org. solvents, sol. in concd H_2SO_4 with a blue to reddish brown color and dyeing cotton from the vat red to grayish black shades of excellent fastness, are produced by the reaction of a 2,2'-dianthraquinonyl-1,1'-carbazole such as 5,5'-diamino-2,2'-dianthraquinonyl-1,1'-carbazole, with the corresponding 4,4'-diamino compd. or 5-amino-4'-benzoylamino-2,2'-anthraquinonyl-1,1'-carbazole, with a halogen anthraquinone compd. such as 1-*p*-tolylazimino-3-bromoanthraquinone, β-chloroanthraquinone or 1-benzoylamino-4-chloroanthraquinone, at an elevated temp. (suitably 180–250°) for 3–4 hrs. (suitably in a high-boiling solvent

such as naphthalene, trichlorobenzene or ethylcarbazole and in the presence of an acid-binding substance). Cf. *C. A.* **25**, 1396.

Vat dyes. KARL WILKE (to General Aniline Works). U. S. 1,790,780, Feb. 3. See *C. A.* **24**, 2305, 2611.

Substituted thioindigo vat dyes. KARL SCHIRMACHER, KARL ZAHN, ERWIN HOFFA and HANS HEYNA (to General Aniline Works). U. S. 1,790,843, Feb. 3. Dyes of the general formula:

wherein X and Y represent H or any substituent, at least one Y being a substituent (the constitution being such that the left-hand side of the formula is not identical with the right-hand side of the formula) are in a dry state red powders, insol. in water, alc. and ether, sol. in nitrobenzene with a red color, sol. in concd. H_2SO_4 with a green color, forming with an alk. hyposulfite yellow vats, from which animal and vegetable fibers are dyed red shades fast to light, Cl and washing, and are obtainable either by subjecting the 1-anils of such diketodihydrothionaphthenes as contain an alkoxy group in *m*-position to the S atom, and also their further substitution products substituted in the nucleus, to reaction with substituted ketothionaphthenes, the corresponding arylthioglycolic-carboxylic acids or with the acylketothionaphthenes obtainable from the said acids by condensation with acetic anhydride, or inversely by subjecting 5-alkylhydroxythionaphthenes, their substitution products substituted in the nucleus or the corresponding arylthioglycoliccarboxylic acids or acylketothionaphthenes obtainable from the said acids by condensation with acetic anhydride, to reaction with the 1-anils of substituted diketodihydrothionaphthenes. By introducing further substituents into one or the other nucleus it is possible to influence the shade toward blue or toward yellow. Numerous examples with details are given.

Stable water-soluble vat dye preparations. JAMES MORTON, JAMES I. M. JONES, BIRKETT WYLAM and JOHN E. G. HARRIS (to Scottish Dyes, Ltd.). U. S. 1,790,759, Feb. 3. Vat dyes (numerous examples of which are given in detailed examples of treatment) are treated with reagents such as chlorosulfonic acid, its salts, fuming H_2SO_4, SO_3 or salts of pyrosulfuric acid, in the presence of a tertiary org. base such as pyridine and of Cu or Zn (suitably with addn. also of a small proportion of $SnCl_2$). The treatment is applicable to dyes of the flavanthrone, indanthrone, dibenzanthrone, benzanthrone, anthraquinone, indigo and halogenated indigo groups, the products being suitable for dyeing cotton, wool or natural or artificial silk from aq. soln. with development of the color of the original dye on treatment with $FeCl_3$ soln., alkali metal hypochlorite or a perborate or permanganate soln.

Indigoid vat dyes. I. G. FARBENIND. A.-G. Fr. 693,903, April 14, 1930. 6-Methylhydroxythionaphthene is condensed with cyclic diketones of the isatinic series or their derivs. Thus, isatin is converted into the α-chloride by means of PCl_5 with the addn. of PhCl, 6-methylhydroxythionaphthene in PhCl is added at about 80° and the mixt. stirred. The product dyes cotton in intense bluish grey shades. Other examples are given.

Indigoid dyes. I. G. FARBENIND. A.-G. (Wilhelm Bauer, inventor). Ger. 513,230, June 13, 1928. Violet indigoid dyes are prepd. by coupling 5-halo-3-hydroxythionaphthenes with reactive α-derivs. of haloisatins, especially of 5,7-dichloro- or -dibromo-isatin. An example is given.

Indigoid dyes. I. G. FARBENIND. A.-G. (Karl Thiess, Theodor Meissner and Hans Heyna, inventors). Ger. 515,134, Feb. 8, 1928. 4,7,4',7'-Tetramethyl-5,5'-dihaloindigos are prepd. by the customary processes from 1,4-dimethyl-3-amino-6-halobenzenes, or from 1,4-dimethyl-3-amino-6-halobenzene-2-carboxylic acids. The same products may be obtained from 1,4-dimethyl-3-aminobenzene or 1,4-dimethyl-3-aminobenzene-2-carboxylic acid, by converting these into 4,7,4',7'-tetramethylindigo and then halogenating. Examples are given.

Indanthrone dyes. LYNNE H. ULICH (to Newport Chemical Corp.). U. S. 1,790,887, Feb. 3. See Brit. 314,803 (*C. A.* **24**, 1520).

Wool dyes. CHEMISCHE FABRIK VORM. SANDOZ. Ger. 515,055, July 13, 1929.

Reddish blue to reddish violet dyes for wool, etc., are prepd. by condensing anthraquinone derivs. contg. substituents exchangeable for an arylamino group, with aromatic amines having at least one halogen atom in the *m*-position to the NH_2 group. The condensation products may be sulfonated. Thus, 1-amino-2-methyl-4-bromoanthraquinone may be condensed with *m*-chloroaniline at 160°, and the product sulfonated. Other examples are given also.

Acid wool dyes. I. G. FARBENIND. A.-G. (Georg Kalischer and Ernst Honold, inventors). Ger. 514,434, Feb. 2, 1928. See Fr. 668,871 (*C. A.* **24**, 1747).

Carboxylic acids of *m*-hydroxyphenylarylamines. I. G. FARBENIND. A.-G. (Leopold Laska and Oskar Haller, inventors). Ger. 515,208, Dec. 2, 1928. Alkali salts of *m*-hydroxyphenylarylamines are heated with CO_2 under pressure. Thus, the K compd. of *m*-hydroxydiphenylamine, heated with CO_2 at 150–70° under 5–10 atm. pressure, yields a product m. 180–1° believed to be *3-hydroxydiphenylamine-4-carboxylic acid*. Numerous compds. derived from substituted *m*-hydroxydiphenylamines are described also. The products are stable and are useful as *intermediates for dyes*.

Dibromodibenzanthrone. MAX A. KUNZ and KARL KÖBERLE (to General Aniline Works). U. S. 1,791,215, Feb. 3. By a process involving brominating dibenzanthrone with Br in chlorosulfonic acid, with addition of Sb, there is obtained a substantially pure dibromobenzanthrone which dissolves in 96% H_2SO_4 to a pure violet soln., in $PhNO_2$ to a pure blue soln. with a pure red fluorescence and in $PhNH_2$ to a pure blue soln. without fluorescence, and which *dyes cotton* from a blue vat with a violet tinge strong marine blue shades which are faster to light than the dyeings obtained from the unhalogenated initial material.

Pyrazolone derivatives. I. G. FARBENIND. A.-G. (Hans Grotowsky, inventor). Ger. 514,421, July 17, 1926. Colored condensation *products useful as dyes or as intermediates for dyes or drugs* are prepd. by treating 1-phenyl-3-methyl-5-pyrazolone, or its derivs. substituted in the phenyl residue, with benzalaniline or other benzalbenzalimines. The reaction is effected in aq. acid soln. at atm. temp. The products are believed to be benzalpyrazolones. Examples are given

Dye intermediates. BRITISH RESEARCH ASSOCIATION FOR THE WOOLEN & WORSTED INDUSTRIES and A. T. KING. Brit. 335,645, July 6, 1929. Aromatic amino derivs. are prepd. by reduction of monoazo dyes other than those contg a β-naphthol component or which form azo-sulfites or which are reducible by SO_2, by the action of alkali bisulfite and sulfite approx. in the mol. ratio of $2NaHSO_3.Na_2SO_3$. Examples are given of the reduction of benzeneazosalicylic acid with an alc. soln. of the mixed reagent to form aniline and aminosalicylic acid and of the reduction of Na azosalicylic acid to aminosalicylic acid.

Intermediates for dyes. I. G. FARBENIND. A.-G. (Winfrid Hentrich, Josef Hilger and Rudolf Knoche, inventors). Ger. 515,468, Feb. 19, 1929. β-Naphthylamino phenoxy fatty acids are prepd. by the reaction of β-naphthol or β-naphthylamine or their substitution products with sulfites and 3- or 4-aminophenoxy fatty acids or their derivs., together or in turn. Thus, Na 2-hydroxynaphthalene-3-carboxylate, heated in aq. soln. with Na 4-aminophenoxyacetate and $NaHSO_3$, loses CO_2 and yields *4-β-naphthylaminophenoxyacetic acid*, m. 156°, after acidifying and cooling. Numerous other examples are given also.

Photochemically decolorizable dyes. I. G. FARBENIND. A.-G. Fr. 693,360, April 4, 1930. Layers for photochem. decoloration are prepd. by using dyes, the speeds of decoloration of which have been harmonized or regulated by hydrogenation or substitution in the aromatic groups joined directly or indirectly to the chromogen. Hydrogenation or the introduction of halogen or a cyano, thiocyano, NO_2, carboxyl or a carbalkoxy group increases the speed of decoloration, while the introduction of an alkyl, aryl, OH, aryloxy or alkoxy group decreases the speed of decoloration. Several examples are given.

Naphthalene derivatives. I. G. FARBENIND. A.-G. Fr. 692,716, Mar. 25, 1930. Derivs. of $C_{10}H_8$ are made by the reaction of carboxylic acid chlorides by the Friedel and Crafts reaction on 1-benzylnaphthalene or on 1-alkylnaphthalenes or their substitution products which are not substituted in the 4 position of the $C_{10}H_8$ nucleus, and treating, if necessary, the resulting products with oxidizing agents. The products are *intermediates for dyes*. Examples are given of the prepn. of 4-benzoyl-1-benzylnaphthalene, m. 110°, 1,4-dibenzoylnaphthalene, m. 106°, 4-benzoyl-1-(*p*-chlorobenzyl)naphthalene, m. 123°, 4'-chloro-1,4-dibenzoylnaphthalene, m. 118°, 1,4-di-*p*-chlorobenzoylnaphthalene, and 4-acetyl-1-benzylnaphthalene, m. 78°, also 4-methyl-1-naphthyl phenyl ketone, 4-benzoyl-1-naphthoic acid, 4-methyl-1-naphthyl methyl ketone and 4-acetyl-1-naphthoic acid, m. 184°.

Dyeing. I. G. FARBENIND. A.-G. Fr. 693,426, April 5, 1930. Very clear colored effects are obtained by printing on a support, previously impregnated with arylides of 2,3-hydroxynaphthoic acid and dried, with printing pastes composed of Na formaldehyde-hyposulfite and vat dyes, drying again, vaporizing rapidly, and finally coloring with a diazotized base. Examples are given.

Applying dyes to fabric. WILLIAM WHITEHEAD (to Camille Dreyfus). Can. 308,605, Feb. 10, 1931. Dyes are applied to a fabric contg. cellulose acetate by spraying with a material contg. a water-insol. dye and ethylene dichloride and a thickening agent.

Dyeing fibrous material. I. G. FARBENIND. A.-G. (Paul Rabe, Hermann Stötter, Berthold Wenk, and Wilhelm Schepss, inventors). Ger. 515,032, Dec. 23, 1925. In fixing dyes on fibrous materials by means of complex compds. of tungstic or molybdic acid, these compds. are treated on the fiber, before dyeing, with reducing agents, *e. g.*, $NaHSO_2$, $Na_2S_2O_4$ or CH_2O.

Dyeing cellulose esters and ethers. I. G. FARBENIND A.-G. (Hermann Wagner, Adolf Kuchenbecker, Richard Huss and C. Erich Müller, inventors). Ger. 511,205, Mar. 4, 1928. Addn. to 509,401 (*C. A.* **25**, 421). Fast blue dyeings are produced on cellulose esters and ethers by coupling with 2,3-hydroxynaphthoic acid or its arylides the diazo compds. from dialkyl, diaryl, or diaralkyl ethers of 2-amino-5-acylaminohydroquinones or their substitution products Coupling is effected on the material to be dyed. Examples are given.

Dyeing cellulose esters and ethers. I. G. FARBENIND. A.-G. (Wilhelm Eckert and Carl E. Müller, inventors) Ger. 515,029. Jan 26, 1928. Cellulose esters and ethers are dyed in yellow shades by means of 4-aminonaphthalimide or its derivs. in which an alkyl, aryl, or aralkyl group replaces H in the imino group. Examples are given.

Dyeing viscose products. I. G FARBENIND. A.-G. (Karl Bormann, inventor). Ger. 515,030, Feb. 18, 1928. Uniform dyeings are obtained with dyes prepd. (1) by coupling the tetrazo compds. of *m*- and *p*-azoxyaniline and their substitution products with suitable components, or (2) by coupling the diazo compds. from 3- and 4-nitroaniline or their substitution products with suitable components and reducing the products with alk. reducing agents. Numerous examples are given.

Dyeing artificial silk. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 693,179, April 2, 1930 Regenerated cellulose silk is dyed in relatively regular shades with dyes obtained by tetrazotizing a mono- or di-sulfonic acid of 4,4′-diaminodiphenylurea or one of its radical derivs. and coupling with 2 mol. proportions of a sulfonic acid or carboxylic acid deriv. of a phenol, naphthol, naphthylamine or *N*-substituted naphthylamine, or with one mol. proportion of a coupling constituent, as above mentioned, and one mol. proportion of an aminonaphtholsulfonic acid or one of its *N*-substituted products or one of its derivs. Examples and a list of components with the shades obtained are given.

Dyeing artificial silk. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 693,790, April 12, 1930. Silk made from regenerated cellulose is dyed by the products obtained by combining a diazotized amine of the C_6H_6 series, contg. no NO_2 group, with an aminonaphtholsulfonic acid in alk. soln , diazotizing again and coupling with another coupling component, all the aminonaphtholsulfonic acids used as final constituents being also coupled in alk. soln. An example and a table of components with the shades obtained on viscose silk are given.

Dyeing furs, hair, feathers, etc. I. G. FARBENIND. A.-G. (Paul Virck, inventor). Ger. 515,031, Sept. 15, 1926. The materials are treated with an aq. soln. of a salt of a naphthalene deriv contg. at least one 3-aminoarylamino group of the C_6H_6 series. They are then treated with an acidified nitrite soln Thus, fur is colored yellow by treatment, at atm. temp., in a bath contg. 2-(3′-aminophenylamino)naphthalene-HCl, followed by treatment with $NaNO_2$ soln. acidified with AcOH. Cf. *C. A.* **25**, 605.

Coloring textiles. HENRY DREYFUS. Fr. 692,734, Mar. 25, 1930. In producing discharge effects on textiles, the material is impregnated with a substance having an acid reaction such as an org. acid before applying the discharge agent The discharged materials may be colored with acylaminoanthraquinone dyes.

Printing with vat dyes. CHARLES J. SALA (to E. I. du Pont de Nemours & Co.). U. S. 1,790,950, Feb. 3. As dye assistants in calico printing pastes, etc., for aiding transfer of the dye to the fabric and producing improved results, there are added substances of the general formula $R_1R_2NAlkOH$ in which Alk represents an aliphatic radical as, for instance, the alkylene group C_2H_4; R_1 represents either H or a hydroxyaliphatic group, as CH_2CH_2OH and R_2, as R_1, represents H or a hydroxyaliphatic group. The use of meno-, di- and triethylolamines is particularly mentioned, also amines contg. ali-

phatic groups with more than one OH group such as a compd. with the group $CH_2CH(OH)CH_2OH$. An example with details of procedure is given.

Machine for dyeing and treating textiles. SMITH, DRUM & Co. Fr. 693,201, April 2, 1930.

Machine for dyeing hanks of thread. GAETANO S. RICCARDI. Fr. 693,037, Mar. 29, 1930.

Condensation products. I. G. FARBENIND. A.-G. Fr. 692,890, Mar. 28, 1930. New products which are of technical value, *e. g.*, *reserving agents* for wool or silk, are prepd. by condensing a halide of an aromatic carboxylic or sulfonic acid with an aromatic diamine to produce derivs. of the carboxylic or sulfonic acid amide sol. in water which contain no free NO_2, NH_2 or OH groups. At least one of the constituents of the reaction is substituted in the position *m*- to the halide or to one of the amino groups. The reaction takes place in water or an org. solvent in the presence of an agent fixing hydrogen halide. Thus, bis(2,4-dichlorobenzoyl)-1,3-phenylenediamine-4-sulfonic acid is prepd. by condensing 1,3-phenylenediamine-4-sulfonic acid with 2,4-dichlorobenzoyl chloride and bis(3,4-dimethylphenylsulfonyl)benzidine-*m,m'*-disulfonic acid from 3,4-dimethylbenzenesulfonic acid and benzidine-*m,m'*-disulfonic acid. Several other examples of compds. of this nature are given.

Reserve effects on textiles. I. G. FARBENIND. A.-G. Fr. 692,888, Mar. 28, 1930. Reserve effects are obtained on half-silk half-wool fabrics by adding to the dye bath contg. a substantive dye or to the mordanting bath, amides of sulfonic or carboxylic acids in which the H atoms of the amide groups are wholly or partly replaced by alkyl-aryl or aralkyl groups. Examples and a long list of substances which may be used are given, including bis(3,4-dichlorophenylsulfonyl)benzidine-*m,m'*-disulfonic acid (by condensing 3,4-dichlorobenzenesulfonyl chloride with benzidinedisulfonic acid in the presence of an acid neutralizing agent) and bis(3,4-dichlorophenylsulfonyl-3'-aminophenylsulfonyl-3''-aminophenylsulfonyl)benzidine-*m,m'*-disulfonic acid (by the reaction of *m*-nitrobenzenesulfonyl chloride with benzidinedisulfonic acid, reducing to the diamine, condensing with *m*-nitrobenzenesulfonyl chloride, reducing again and condensing the product with 3,4-dichlorobenzenesulfonyl chloride)

Textiles. HERMANN BOLLMANN and BRUNO REWALD. Fr. 693,887, April 14, 1930. Textiles are improved by adding to the baths used for treating fibers, threads or cloth a certain amt. of lecithin.

Waterproofing textiles. ALEXANDER NATHANSOHN. Fr. 693,803, April 12, 1930. Textiles are made waterproof by incorporating in them, by a gentle treatment with esterifying derivs. of higher fatty acids, the corresponding radicals of fatty acids in amts. which do not notably pass the content of the natural fibers in these radicals. Examples are given of the treatment of textiles with stearyl anhydride, stearyl chloride, etc., in benzine, C_6H_6, CCl_4, etc.

Sizing or softening agent for fibers. HERMANN BOLLMANN and BRUNO REWALD. Fr. 692,528, Mar. 21, 1930. A sizing, gumming or softening agent for fibers is composed of an emulsion of phosphatides of vegetable origin (particularly phosphatides from soy beans), fatty oils and (or) fatty acids in water. A small quantity of Turkey-red oil or mineral oil may be added to the emulsion.

Improving the qualities of fibrous materials. I. G. FARBENIND. A.-G. Fr. 693,019, Mar. 29, 1930. Fibrous materials such as artificial silk are improved by applying to their surface or incorporating with them aliphatic or cycloaliphatic compds. of high mol. wt., or mixed aliphatic- or cycloaliphatic-aromatic compds. which possess aliphatic or cycloaliphatic radicals of high mol. wt. or their salts.

Treatment of fabric. HERBERT PLATT and CYRIL M. CROFT (to Camille Dreyfus) Can. 308,437, Feb. 3, 1931. Fabric contg. cellulose acetate has the "sticking" point increased by treatment for 45 min. at 40° with a soln. contg. 10–50 g. of basic Al acetate per l., and about 50–100 cc. of AcOH per l.

Treating cellulose materials. HENRY DREYFUS. Fr. 692,796, Mar. 26, 1930. Materials of or contg. cellulose have their qualities improved by a treatment with organo-mineral acids or concd. aq. solns. thereof, *e. g.*, aliphatic or aromatic sulfonic acids. The threads may be spun directly from the spinning nozzles into the acids. Examples are given of the use of sulfoacetic acid.

Artificial threads, films, etc. HENRY DREYFUS. Fr. 693,240, April 3, 1930. Threads, films, ribbons, etc., made of or contg. cellulose derivs. are treated with organo-mineral acids such as sulfonic acids or concd. solns. thereof whereby the mech. resistance and elasticity are improved. Solns. of the cellulose derivs. may be extruded into the acids. Examples are given of the use of sulfoacetic acid, ethylenesulfonic acid and methylsulfonic acid. Cf. *C. A.* **25**, 1103.

Artificial silk. BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 335,583, March 16, 1929. Materials of cellulose acetate or other cellulose derivs. rendered insensitive to the delustering action of moist steam or other hot or boiling aq. media as described in Brit. 332,187 (*C. A.* 25, 205) and Brit. 332,231 (*C. A.* 25, 218) are used together with other cellulose ester or ether products sensitive to such delustering action, so that by use of a delustering material on the product design or pattern effects may be produced by its selective action. Numerous details and examples are given.

Artificial wool. MICHEL DASSONVILLE. Fr. 693,321, July 12, 1929. A machine is described for treating cellulosic filaments coming from the coagulating baths to give them the appearance of wool.

Oleaginous composition suitable for conditioning wool. AUGUSTUS H. GILL. U. S. 1,791,057, Feb. 3. In order to prevent spontaneous combustion of material to which oleaginous compns. are applied, about 1–2% of hydroquinone is added to the compn., *e. g.*, to "red oil" for lubricating wool.

Washing wool, textiles, etc. I. G. FARBENIND. A.-G. Fr. 692,834, Mar. 27, 1930. Aromatic sulfonic acids or their salts, possessing in the ring or in a substituent or both, one or more org. radicals with a chain of more than 5 C atoms, are used for washing wool, textiles, etc. Examples are given of the use of the Na salt of hexylnaphthalene-, octylnaphthalene-, cetylnaphthalene- and *N*-dihexylnaphthylaminesulfonic acid. Substances such as cyclohexanol, AmOH, cyclohexanone and CCl_4 may also be added. Cf. *C. A.* 24, 734.

Mothproofing wool, etc. I. G. FARBENIND. A.-G. Brit. 334,886, June 10, 1929. Materials such as woollen fabrics are treated with compds. obtained by condensing phenols with aralkyl compds. such as aralkyl halides, alcs., and ω-sulfonic acids, and then sulfonating, or by condensing sulfonated phenols with aralkyl compds. Various examples are given, one of which involves the use of the product obtained by condensing 2-sulfo-4-chlorophenol with tetrachlorobenzyl chloride.

Mothproofing fur, wool, etc. I. G. FARBENIND. A.-G. (Max Weiler, Berthold Wenk, and Karl Berres, inventors). Ger. 513,387, July 13, 1929, and 513,388, July 18, 1929. Addns. to 503,256 (*C. A.* 24, 5169). The materials are treated with asym. hydroxydi- or tri-arylmethane derivs. obtainable by condensing *p*-chloro- or *p*-bromophenol (or their substitution products having one *o*-position to the OH group unsubstituted) with aromatic hydroxy alcs. or hydroxyhydrols or their anhydrides or derivs., which are themselves obtainable by condensing an aldehyde with one of the phenols mentioned. A suitable reagent is pentachlorodihydroxytriphenylmethanesulfonic acid, prepd. by condensing 2,4-dichlorophenol with the hydrol anhydride obtainable from *o*-sulfobenzaldehyde and 2,4,5-trichlorophenol (513,387). Alternatively, the materials may be treated (1) with bis(hydroxybenzylated) aromatic hydroxy compds. having halogen in the *p*-position to the OH groups, but free from COOH or SO_3H groups, or (2) with nuclearly mono- or di-benzylated *p*-halophenols free from COOH or SO_3H groups and contg. no OH groups in the benzyl nucleus, or (3) with halogenation products of hydroxydi- or tri-arylmethanes not contg. COOH or SO_3H groups (513,388). Cf. *C. A.* 25, 422.

Hydroxyarylmethanes. I. G. FARBENIND. A.-G. Brit. 335,547, April 19, 1929. Mixts. of hydroxydi- and hydroxytri-arylmethanes, or mixed hydroxydi- and hydroxytri-arylmethanes, *suitable for mothproofing wool, furs, etc.*, are prepd. by condensing, in an acid medium, one mol. proportion of formaldehyde with 2 mol. proportions of a mixt. of phenols comprising a *p*-halogenated phenol or phenols with other phenols, or by similar condensation of 1 mol. proportion of an aromatic aldehyde such as mixed *o*- and *p*-chlorobenzaldehydes or *o*-sulfobenzaldehyde (but excluding aromatic hydroxy aldehydes and their sulfonic, carboxylic and sulfo-carboxylic derivs.) with 2 mol. proportions of a mixt. of phenols comprising *p*-alkylated phenols or their mixts. with other phenols, or a *p*-halogenated phenol mixed with other phenols (all the *p*-alkylated and *p*-halogenated phenols having free *o*-positions). Several examples are given and H_2SO_4, $AlCl_3$, $FeCl_3$ or a mixt. of H_2SO_4 and HOAc may be used as condensing agents. Cf. *C. A.* 24, 6036.

Rubberized cloth. E. I. DU PONT DE NEMOURS & CO. Fr. 693,890, April 14, 1930. Rubberized cloth is coated with a final layer of asphaltic varnish and heated to a temp. below the softening point of the asphalt. Cf. *C. A.* 24, 1524.

Apparatus for cleaning benzine used for degreasing and decoloring. MOÏSE DUVAL. Fr. 693,006, Mar. 29, 1930.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Studies in the painting of wood. I. Influence of wood structure on paint behavior. J. H. HASLAM AND S. WERTHAN. *Ind. Eng. Chem.* **23**, 226-33(1931).—In order better to understand the relationships between wood and paint films, H. and W. examd. microscopically the wood surface, the paint film and the interface of the 2. Differential staining of wood-paint sections made possible a study of the penetration of paint into soft woods of several species. The method is described in detail. Woods of apparent uniformity are revealed under the microscope as irregular. Differences in wood structure which have an important bearing on the behavior of the paint film include: (1) the sharpness of transition of spring wood to summer wood, (2) the distribution of pits on the fiber walls and their permeability, (3) the direction of the medullary rays with respect to the surface (flat- *vs.* edge-grained boards) and (4) the existence of resin ducts. A study of the shrinking and swelling of wood led to the discovery that the expansion of the summer wood is often greater than the over-all expansion of the wood. In such cases the swelling of summer wood is compensated for by compression of the spring wood. The expansion of the summer wood is less than the distensibility of a new paint film but exceeds many times the distensibility of a film 8 months old; hence the early loss of paint over summer wood. Penetration of paint liquids occurs through the pits and medullary rays. Penetration is uneven on flat-grained surfaces because of the existence of ray openings which occupy about 20% of the area. Uneven penetration results in nonuniformity of paint film and consequent early failure of paint film. Penetration of vehicles becomes more regular in the order: oil + turpentine, raw oil, bodied oil, varnish. H. K. SALZBERG

Effect of wood grain on paint durability. H. A. GARDNER. *Am. Paint & Varnish Mfrs.' Assoc. Circ.* No. 377, 128-30(1931).—A Pb-Zn house paint was applied over various primers to Ark. soft pine characterized by flat, angle and vertical grain. The primers were (I) the paint itself thinned according to directions, (II) Al-spar varnish, (III) $PbCrO_4$ in oil and (IV) a graphite paint. Superior results were obtained on vertical grain with (IV). G. G. SWARD

Why some wood surfaces hold paint longer than others. F. L. BROWNE. U. S. Dept. Agr., *Leaflet* **62**, 4 pp.(1930).—It is not necessary for painters to change the compn. of the priming coat for the different softwoods. Moisture gaining access to the backs of painted boards causes failure by blistering, peeling and discoloration The painting characteristics of a board depend on the amt. and distribution of the summer wood. The density of a softwood board measures roughly its ability to hold paint coatings. Cedars, cypress and redwood hold paint best and northern, western and sugar pines almost as well, whereas with southern pine and Douglas fir and western larch, serious flaking from the summer wood occurs sooner than with the former species Other conifers lie between. Wood of the same species varies greatly in texture and density and therefore in painting characteristics. Knots and pitch give trouble. Edge-grain boards hold paint better than flat-grain. Southern exposure is the hardest on paint. Repainting should be done before the old coating has flaked or the bare wood is exposed. ALFRED L. H. KAMMERER

Why wood painting research becomes a problem in forestry. F. L. BROWNE. *J. Forestry* **28**, 1136-45(1930); cf. *C. A.* **24**, 2313, 3913.—The variability in paint service on different woods is considerable. Density, ring-width and type of grain, all widely variable, have a great influence on the integrity of paint films. Progress in wood painting technology therefore concerns the forester. Results of tests described in previous papers are given. ALFRED L. H. KAMMERER

Commercial paints: substitutes for white lead and anti-corrosion paints. A. VILA. *Chimie & industrie* **24**, 1052-67(1930); cf. *C. A.* **22**, 3998.—The results obtained after 4 yrs.' exposure to the atm. are given, including photographs of the painted surfaces and of sections through them. Ti oxide and lithopone paints had the highest covering power, followed in order by ZnO, one of the white leads, mixed white pigments, Sb oxide and finally a white-lead paint. As regards resistance to weathering, the pure basic pigments (white lead, ZnO) which can combine with the acid radicals of the oil showed least loss to rubbing (light sponging with city or distd. water), while the dust thus removed from these paints had the highest content of org. matter; the Sb paint (Timonox) was already too badly deteriorated to make it worth while making these detns. Various accelerated aging tests for anti-rust paints were tried out, but apparently did not deteriorate the paint any more rapidly (in some cases less) than ex

posure to the atm. or to fresh or sea water. As the value of these paints depends essentially on their impermeability, the following test is suggested: Apply 2 coats of the sample to be tested over the whole of a small Al plate and allow to dry normally. Fill the hollow of the plate with a soln. of NaCl and $HgCl_2$ in distd. water and let stand at atm. temp.; if the coating is impermeable the soln. evaps. without producing any corrosion, but if it is not impermeable the $HgCl_2$ reacts vigorously with the Al as soon as the soln. has penetrated to the metal. The tests showed that at the present time a no. of com. French anti-corrosion paints contg. no Pb salts are fully equal to, or better than, the old minium paints. A. PAPINEAU-COUTURE

Technical analysis of titanium white. J. PFANHAUSER AND S. TOMASZEWSKI. *Przemysl Chem.* **14**, 353–5(1930).—The soln. contg. Ti is acidified with HCl with exclusion of air and then reduced with Zn for about 2 hrs. at 70–80°. High temp. causes the pptn. of insol. H_2TiO_3. The soln. is then either titrated with 0.1 *N* $KMnO_4$ at 60–70° under CO_2 with exclusion of air or is reduced with an excess of ferrous NH_4 sulfate, which is then titrated back without the need of excluding air. A. C. Z.

Thickening of red lead. W. VAN WÜLLEN-SCHOLTEN. *Farben-Ztg.* **36**, 644–5 (1931).—The consistencies of pastes prepd. with (I) highly dispersed and (II) normal red lead and varying amts. of linseed oil were detd. at intervals during several months and plotted. The curves for I passed through a min., the breadth of which varied directly with the amt. of oil, 20% being the least amt. of oil for which the breadth was very great. The consistencies of II increased continuously from the time of their prepn. The settled layers of I were softer than those of II. In order to det. which oxide, PbO or PbO_2, is responsible for the thickening properties of red lead, mixts. contg. varying amts. of these oxides were ground with linseed oil. The paste contg. 100% PbO_2 behaved like highly dispersed red lead and the mixts. with the highest percentages of PbO_2 had the softest settlings. In order to study the effect of the manner of prepg. the pastes, 84 parts red lead was ground with 9, 12 and 16 parts oil, resp. After different intervals, the oil content of all the pastes was brought up to 16%. The results showed that softer pastes are obtained if only a portion of the oil be used at first. G. G. SWARD

New methods of preparing chrome oxide green and hydrated chrome oxide green. A. C. HEINEMANN. *Farbe u. Lack* **1931**, 6.—A few of the recent German patents for prepg. the chrome oxide greens are briefly reviewed. G. G. SWARD

Survey of preparation of alkali chromates. ALFRED HEINEMANN. *Farbe u. Lack*, **1931**, 26. The author briefly reviews a few German and English patents on extn. of Cr from its ores. G. G. SWARD

The toxic action of varnish, paints and polishes. DELFÍN L. BARRIOS AND JOSÉ S. DEVOTO. *Semana méd.* (Buenos Aires) **1931**, I, 252–7. A review is given of poisoning by vapors of solvents (PhH, PhMe, AcOEt and $AcOC_5H_{11}$). A. E. MEYER

Spirit of turpentine in varnishes and paints. A. GÉRARD VAUDIN. *Bull. inst. pin* **1931**, 4. The merits of spirit of turpentine over white spirit are briefly discussed. A. PAPINEAU-COUTURE

Oiticica oil. G. G. SWARD. *Am. Paint & Varnish Mfrs.' Assoc. Circ.* No. **377**, 120–5(1931).—A white acetone-insol. material, which did not appear to be β-eleostearin, was obtained when oiticica oil was exposed in a thin layer to ultra-violet light. The yield was about 25%. A 25-gal. *ester-gum varnish* prepd. with oiticica oil compared favorably with one prepd. with tung oil. The literature of oiticica oil is briefly reviewed and a bibliography is given. G. G. SWARD

Scheiber oil. G. G. SWARD. *Am. Paint & Varnish Mfrs.' Assoc. Circ.* No. **377**, 126–7(1931).—Some of the phys. properties of a drying oil prepd. from castor oil were: $d_{15}^{15.5}$ 0.937, I no. (Wijs) 120.5, n^{25} 1.487, viscosity (G-H scale) G, and color (Hellige) 1L-1. When subjected to the Brown heat test, the oil did not gel in 2 hrs. The properties of a blown oil and of a stand oil prepd. from the raw oil are also given. G. G. SWARD

Oxidation products of drying oils. I. β-Eleostearin from tung oil. R. S. MORRELL AND S. MARKS. *J. Soc. Chem. Ind.* **50**, 27–36T(1931); cf. *C. A.* **24**, 2901.—In the oxidation of the β-eleostearic glyceride the first product is a diperoxide, followed by a change to a monoperoxide, $(CH_3(CH_2)_3\underset{\diagdown O_2 \diagup}{CH.CH.CH}:CHC(OH):C(OH)(CH_2)_7\text{-}COO)_3C_3H_5$. On methylation, Me esters, sol. and insol. in light petroleum, are formed. The max. number of methoxyl groupings which can be introduced is two. Attempts to methylate Me ricineolate were unsuccessful and resulted in the production of a methyl

ester of an acid isomeric with linoleic acid. The Me esters are oxidized by $KMnO_4$ to valeric acid and an intermediate C_{18} or C_{14} acid. Reduction by H_2 with Pd causes addition of two or four atoms of H. Treatment of the Me esters with HI or HBr causes reduction of the peroxide group and withdrawal of the methoxyl groups to form $CH_3(CH_2)_3CH.CHCH:CHCHCH(CH_2)_7CO_2H$. The evidence in favor of pos. and neg. polarity of the peroxide groups has been strengthened. The yellowing of drying films is due to rancidity, caused by disruption of the remote peroxide and the action of strong bases on the near peroxide to form colored salts. The inert character of the central double linking is very marked. There is a strong associating power of both peroxide groups. The peroxides are very stable in acid media. Polymerization of the oxidized esters is accompanied by a rise in refractive index. The loss in wt. of linoxyn films is connected with degradation beginning at the remote peroxide grouping. A scheme of orientation on the lines of Staudinger's representation of polymerides is suggested.

H. M. STARK

Notes on aircraft finishes. H. A. GARDNER. *Proc. Am. Soc. Testing Materials* 1930, Preprint No. 33, 37–45.—A discussion of various types of wing dopes. Acetate dope for priming coat evidenced lower tautness with good strength, while nitrate dope showed good tautness and satisfactory strength. Nitrate dopes properly applied and protected from light by Al-pigmented outer coats showed that the underlying coats of nitrate dope were not broken up by sunlight, the strength of the fabric was maintained and excellent tautness was effected. Two thin coats of clear spar varnish were applied over the Al-pigmented dopes to make it smooth. Properly compounded nitrocellulose lacquer coatings are now being applied to the top-side wing surfaces. The newly developed lacquer-varnish coatings usually contg. nitrocellulose properly compounded in soln. with phthalic anhydride-glycerol resins appear to offer the advantages of quick drying highly water-resistant surfaces and exceptional durability. W. H. B.

The preparation of low-viscosity cellulosic collodions. CH. STARK. *Rev. gén. mat plastiques* 6, 649–59(1930).—A brief review is given of the development of these collodions to meet the modern requirements of nitrocellulose lacquering and varnishing.

A. PAPINEAU-COUTURE

Nitrocellulose lacquers. HANS WOLFF AND B. ROSEN. *Farben-Ztg.* 36, 736–7 (1931).—Ordinary kauri copal, in either the natural or "run" states, tends to sep. as a gel in films of nitrocellulose lacquers contg. it. Solvent-extd. kauri, however, is not subject to this defect. In hardness, abrasion resistance, flexibility, tensile strength and elongation, films of nitrocellulose lacquers contg. extd. kauri compared favorably with those contg. ester gum. Films contg. Manila copal were inferior to those contg shellac and extd. kauri.

G. G. SWARD

Compatibility of resins with nitrocellulose solutions. HARRY E. HOFMANN *Ind. Eng. Chem.* 23, 127–30(1931).—Although nitrocellulose, ester gum and AcOBu or AcOAm are compatible in all proportions and give clear films, many other systems give cloudy films. Of 132 combinations prepd by mixing nitrocellulose with 11 resins and dissolving the mixt. in 1 of 12 solvents, 43 gave clear solns. and films; 15 required only the addn. of a plasticizer; 12 cleared up on the addn. of a plasticizer and diluent, and 3 cleared up on the addn. also of ester gum; 59 gave cloudy films in all tests. Some of the resins, notably vinyl acetate, rosin, dammar and Rezyl 12, are compatible with nitrocellulose in most of the solvents. Ester gum and Amberol H-9 could not be made compatible in systems contg. diacetone alc., Et lactate, Cellosolve or Cellosolve acetate. Kauri and pontianac could be made compatible only in systems contg. AcOEt, Cellosolve or Cellosolve acetate. Manila and shellac are incompatible in most systems and cumar could not be made compatible in any system. Incompatibility of resins with nitrocellulose in certain solvents is ascribed to lack of miscibility of resin and nitrocellulose rather than to pptn. of resin by solvent. Careful examn. of incompatible systems reveals the existence of 2 homogeneous phases but no ppt. Solvents and diluents belong to either an alc. or a hydrocarbon type and resins to either an alc.-sol. or a hydrocarbon-sol. type. In general, compatibility is most readily obtained by using solvents and resins of corresponding types, *e. g.*, an alc.-type solvent and an alc.-sol. resin. However, in those systems requiring the addn. of diluent or ester gum, it is found that the type of diluent or resin which produces compatibility is of the type opposite to that of the diluent or resin originally present. The ability of a plasticizer to clear up incompatible systems depends upon the nature of the plasticizer. A clear lacquer gives cloudy films when that type of solvent which makes for incompatibility is allowed to conc. in the film during drying.

H. K. SALZBERG

Cativa resin. L. P. HART. *Am. Paint & Varnish Mfrs. Assoc. Circ.* No. 377, 131–2(1931).—A balsam-type resin from the tree *Prioria copaifera*, Griseb, made into a tung-oil varnish gave a product whose films were somewhat softer than those of varnishes made from the common resins. G. G. SWARD

The importance of glycerol and glycol in industry. G. PETROV. *Masloboino Zhirovoe Delo* 1929, No. 7, 18–21.—The new developments in the application of glycerol and glycol in the prepn. of synthetic resins by condensation with polybasic acids are reviewed, and attempts to prep. "linoxyn films" from the ethyl esters of fatty acids of linseed oil are described. The results of these expts. were negative and P. concludes that glycerol cannot be replaced in the drying oils by lower alcs. E. BIELOUSS

New method of determining the acid number of copals. ZYGMUNT LEPPERT. *Przemysl Chem.* 15, 1–5(1931).—One g. finely powd. copal is boiled in 20 g. terpineol under a reflux until dissolved. Some difficultly sol. copals may take 1–3 hrs. The hot soln. is diluted with 20 cc. CH_3OH and on cooling is titrated with 0.1 *N* KOH. With difficultly sol. copals the hot terpineol soln. is treated with 20 cc. C_2H_5OH and 20 cc. alc. 0.5 *N* KOH, and heated for about 15 min. Since the soln. turns dark it is diluted with 200 cc. C_2H_5OH and after cooling titrated back with 0.5 *N* H_2SO_4 against phenolphthalein. Compared with the methods of Gardner, Dietrich, Marcusson and Winterfeld this method has the advantages in that it gives consistent results in a series of detns. on the same copal; it is general and does not require a different set of solvents for every kind of copal; the results obtained are very probable. The acidity values obtained by this method on various kinds of copals may be used for comparing their acidities. Tables of the acidity values of many kinds of copals are given. A. C. Z.

Production of oleoresin from Pinus halepensis of Spain. VICENTE CUTANDA AND MARIANO SEVILLA. *Servicio Forestal de Investigaciones y Experiencias* 2, No. 5, 29–42(1929).—The production of oleoresin from stands of *P. halepensis*, which are found along the Mediterranean coast, began during the World War. At present about 600,000 trees of this species are being turpentined. The oleoresin is being distd. at 7 different plants. The yields per tree per yr. vary from 1.05 to 4.30 kg., depending upon growing conditions. These yields compare favorably with those from the more commonly worked *P. pinaster* (maritime pine). The compn. of the oleoresin as given by Lacrue (*C. A.* 23, 5037) is discussed. The rosin is somewhat low in grade because of a greenish tinge. Cleaning the gum before distn., according to the usual Spanish practice, is especially advantageous on account of the presence of much tannin. Water is sepd. by decantation from the oleoresin before distg. by allowing the mixt. to stand in closed vessels for 10–12 hrs. The rosin is invariably sunned to improve its color. The turpentine must be distd. to remove its greenish color. A proposed alternative is filtration through $(CO_2H)_2$. H. K. SALZBERG

Azo dyes [for red varnishes] (U. S. pat. 1,791,444) 25.

Paint composition. RICHARD L. BRAGDON and DALE F. MCFARLAND. Can. 308,612, Feb. 17, 1931. Turpentine is added to paint and then there is added a soln. made up of water, shellac and $NaHCO_3$.

Weather-resisting paints. I. G. FARBENIND. A.-G. Brit. 335,626, May 2, 1929. There is incorporated with paints or other coating materials at least such a quantity of pptd. ZnO (dried by heating to a temp. not materially exceeding 500°) as is necessary to combine into soaps all free or combined fatty acids present in the binding agent such as linseed oil or China wood oil. Various details and examples are given.

Roof paint. JOSIAH D. WALSTON (to Black Diamond Paint Co.). U. S. 1,791,455, Feb. 3. A paint is formed from ingredients including coal tar, rosin, PbO, $ZnSO_4$, $CaSO_4$, gasoline and kerosene.

Paints, stains, etc., comprising colloidal dispersions. SAMUEL CABOT (to Samuel Cabot, Inc.). U. S. 1,791,119, Feb. 3. Pigment particles of colloidal fineness are carried in suspension in an org. dispersion medium such as linseed oil and turpentine or solvent naphtha together with a semi-plastic treated oil such as a linseed oil jelly.

Paint filter. RUDOLF SCHMID. Ger. 515,439, Sept. 28, 1929.

Indelible ink. MARCEL ROURE. Fr. 692,929, June 28, 1929. Indelible ink is made by dissolving salicylic acid 2, gum arabic 25, alum 100 and oxalic acid 50 g. in 1 l. of water, boiling and adding 100 cc. of ox gall and 100 cc. of alc. to make soln. A. Aniline dyes according to the color of ink desired are added to a boiling soln. of 20 cc. of HCl in 1 l. of water to form soln. B. Solns. A and B are mixed, allowed to stand and then filtered.

Ink for producing grained effects on wood. E. I. DU PONT DE NEMOURS & Co Ger. 515,232, April 18, 1929. See Brit. 315,214 (*C. A.* **24**, 1753).

Emulsions of oxidized drying oils, varnishes and lacquers. PAUL C. VAN DER WILLIGEN and N. V. NEDERLANDSCHE LINOLEUMFABRIEK. Dutch 22,635, Sept. 15, 1930. Stable emulsions of oxidized oils are obtained by keeping the p_H constantly above 7 during the oxidation by air. NaOH or NH_3 (not lime) is added during the reaction which is carried out between 30° and 70°. A buffer soln. may be employed for the same purpose. Cf. *C. A.* **24**, 2903.

Varnish. BAKELITE CORP. Fr. 693,899, April 14, 1930. A resin varnish contains a non-hardenable resin such as colophony or gum-lac and an infusible transformation product of a hardenable resin such as phenol-aldehyde resins dispersed colloidally in the non-hardenable resin.

Varnish, etc. BAKELITE CORP. Fr. 690,763, Feb. 27, 1930. A coating compn. is made by the reaction of a phenol, *e. g.*, cresol, and a fatty oil such as abrasion oil in the presence of $(CH_2)_6N_4$ at temps. of 190-200°. The reaction product may be heated anew in the presence of an agent contg. CH_2 such as paraformaldehyde.

Lacquers, varnishes, etc. SOC. LÉVY, SAMUEL & LÉVY. Fr. 692,912, July 3, 1929 Lacquers, varnishes and enamels which are insulators for heat and electricity and are resistant to chem. agents are prepd. by bringing into soln. or pseudo-soln. the product called "thiolite" (see Fr. 549,811) which is obtained by treating with S or S_2Cl_2 the condensation products of phenols with aliphatic aldehydes such as CH_2O. Solvents used are alcs., carbides, furfural, cyclohexanol, pyridine, molten or dissolved $C_{10}H_8$, etc.

Lacquers. I. G. FARBENIND. A.-G. Ger. 515,056, June 26, 1926. As solvents for lacquer materials, esters are used b. above 150° and derived from chlorinated monobasic fatty acids having not more than 12 C atoms in the mol., and mono- or polyhydric aliphatic, aromatic or hydroaromatic alcs. free from halogen. Lacquers contg. butyl chloroacetate and glycol monomethyl ether chloroacetate are described.

Nitrocellulose lacquers and plastics. I. G. FARBENIND. A.-G. Ger. 515,057, July 2, 1929. Nitrocellulose lacquers and plastics are colored blue with the dyes obtainable from hydrochlorides of dialkylnitrosoanilines and dialkyl-*m*-aminocresols. 2-Dimethylamino-2'-diethylamino-3'-methyloxazine chloride is a specified dye.

Lacquers from polymerized vinyl esters. CONSORTIUM FÜR ELEKTROCHEM. IND. G. M. B. H. (Wolfram Haehnel and Willy O. Herrmann, inventors). Ger. 514,435, May 16, 1926. The polymerization products are dissolved in EtOH and diluted with about 5% of water or other non-solvent for the products. Other resins, etc., may be added to the solns. Examples are given.

Composition for coating wire gauze or netting. E. HAVER. Brit. 335,775, Oct. 28, 1929. Wire gauze or netting is coated or filled with a soln. of a cellulose deriv., *e. g.*, cellulose acetate, contg. a small proportion (suitably about 1-2% of the amt. of the cellulose deriv.) of hydrocarbon material such as rubber, paraffin or paraffin oil, and the coating is preferably provided with a thin layer of a transparent air- and water-proof material having a high m. p. such as a wax, fat, paraffin, resin or varnish dissolved in a volatile solvent having a softening action on the underlying coating. Several examples and formulas of different mixts. are given.

Plastic materials. ANDRÉ SAMUEL. Fr. 693,739, July 22, 1929. A plastic material is made from a homogeneous soln. of ebonite and the sulfonation product of a phenol-CH_2O resin known by the name of "thiolite" (cf. Fr. 549,811). A mixt. of alc. and benzine may be used as solvent.

Purifying resins. MARIUS TOURNEL. Fr. 693,292, July 8, 1929. Resins such as colophony are purified by projecting the powd. resin into water contg. caustic lye, raising the temp. and adding an electrolytic soln. which ppts. the colloids formed. The top liquid contg. coloring substances, etc., is siphoned off, and the ppt. is suspended in water, treated with Na_2CO_3 and again pptd.

Synthetic resins. CANADIAN ELECTRO PRODUCTS CO., LTD. Fr. 692,718, Mar. 25, 1930. Resins are made by the reaction of partly or completely hydrolyzed polymerization products of vinyl esters with aldehydes. Several examples are given using vinyl acetate polymerization products and AcH or CH_2O.

Artificial resins. LOUIS C. F. PÉCHIN. Fr. 693,844, April 14, 1930. A phosphorescent artificial resin is made by incorporating sulfides in phenol-CH_2O resins during their manuf.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Detection of vegetable and animal fats. L. AUERBACH. *Chem. Umschau Fette, Oele, Wachse u. Harze* **38,** 11–2(1931).—The digitonid method and the conversion of the digitonid into its acetate with a definite m. p. readily distinguish between wholly vegetable and animal oil, but at present no method is known which sharply detects animal fats in a vegetable fat or oil. For such detection A. places the greatest reliance upon the following methods: convert the digitonids into acetates, saponify, ext. the alcs. with petr. ether and det. the m. p. Exam. the crystals microscopically: in most mixts. A. found the crystals of cholesterol and of phytosterol side by side and in one case the peculiar cone-shaped mixed crystals described in the literature. P. ESCHER

Determination of the specific gravity of solid fats and other solid substances. W. NORMANN. *Chem. Umschau Fette, Oele, Wachse u. Harze* **38,** 22–3(1931).—Directions are given for the detn. of the sp. gr. by means of N.'s special dilatometer. P. E.

Fat from the grape waste products. LABORATORY OF ANALYSIS, DEPARTMENT OF OILS AND FATS. *Ind. olii minerali e grassi* **10,** 122–3(1930).—Grape wastes, after the extn of tartaric acid, contain 8–10% (on the dry product) of a dark-green fat, with high % of solid fatty acids having a high sapon. no. Some of the fat is combined with Ca. The wet waste contains 21–23% of fat and 24% of non-fatty extractive prepns., chlorophyll, mucilaginous matter and gum resins. From a dry grape waste sepd. from the kernels the oil yield is 2–5%; when it is disintegrated in a mill, the yield is 10%. The fat is best extd. after the recovery of the alc. and tartaric acid. It is principally in the seeds and skins, and in small quantity in the pulp and stalks. A sample of fat from black Puglia grape waste, without kernels, contained 6.30% of water. A portion was insol. in Et_2O, the sol. part with hot petroleum ether, gives a ppt. after 1 hr. By extg. with acetone, Et_2O and petroleum ether successively, there is obtained a semi-solid dark olive-green fat with much extraneous matter The part sol. in cold petroleum ether has 17.50 oleic acid acidity, 73.88 total fatty acids, 20.92 unsaponifiable matter, 1.51% oxidized acids and hydroxy acids The unsaponifiable matter obtained from grape fat forms a dark orange-yellow cryst. mass. The fatty acids have I no. 105.20, neutralization no 189.35, av. mol. wt. 296.30, I no. of liquid fatty acids 72.90, of solid acids 27.10. By crystn. of the K salts of the fatty acid from acetone there are obtained a fraction, m. 53–54°, contg. palmitic and stearic acids and a fraction, m. 71°, contg. an amorphous acid The liquid fatty acids give not more than 1% of hexabromide m. 178° (linolenic acid); they contain oleic and linoleic acids. The part insol. in petroleum ether is free from saponifiable substances and contains a small amount of Fe-Al ash, with little Ca and Mg. It contains mostly mucilaginous, non-fat extractive substances. R. S.

The oleic acid rancidity of fats. III. Catalytic influence in rancidity reactions. K. TÄUFEL AND J. MÜLLER. *Z. angew. Chem.* **43,** 1108–12(1930); cf. *C. A.* **25,** 426.—Rancidity expts. with oleic acid and oleic ethyl ester were made by exposing them in small dishes to atm. oxidation, with and without catalysts, and noting the intensity of the Kreis color reaction in one series and the wt. increase of the fats in another. The following substances were tried as catalysts: hydroquinone, phenol, β-naphthol, salicylic acid, KCN, Fe_2O_3, $FeCl_3$, Fe oleate, Cu oleate and Cu acetate. The results in the 2 series did not run parallel in all cases; β-naphthol prevented rancidity in the Kreis series and was indifferent in the wt. series. Oleic acid was, in most cases, influenced less than the ethyl ester; hydroquinone acted throughout as a strong neg. catalyst; $FeCl_3$ acted in the Kreis series as a strong positive catalyst; Fe oleate appeared to be a negative catalyst. P. ESCHER

Hardening unsaturated fatty acids containing triple bonds. A. STEGER AND H. VAN LAARHOVEN. *Chem. Umschau Fette, Oele, Wachse u. Harze* **38,** 23–4(1931).—By following the hydrogenation of stearolic Et ester with its triple bond by means of Kaufmann's thiocyanate method, the latter was found to be an equil. reaction which varies in results with the temp., time and concn. and excess of the thiocyanate. The hardening of stearolic Et ester occurs in steps, the triple bond being first reduced to a double bond before any stearic acid begins to form. Harris's ozonation method shows the absence of any shifting of the triple bond during hydrogenation. P. ESCHER

The fat and oil of Sapium sebiferum seeds. ANON. *Bull. Imp. Inst.* **28,** 429–31 (1930).—The seed consisted of 69.1% seed coats and 30.9% kernels. Extn. with petroleum ether yielded 33.9% oil (on the dry basis), having consts. agreeing fairly well with those published by Bolton for Chinese vegetable tallow, except the m. p. (37.8°) which was considerably lower but in good agreement with Nakamori (*C. A.* **14,** 1452).

The kernels yielded 61.7% oil (on the dry basis), which had consts. agreeing well with those recorded by Bolton for stillingia oil. A. PAPINEAU-COUTURE

Some developments in the oil palm industry. H. M. LANGTON. *Ind. Chemist* **7**, No. 73, 71–4(1931). E. H.

The lipase of olives and olive oil. E. PANTANELLI AND S. VERDESCA. *Rend. accad. sci. Napoli* [3], **36**, 76–83(1930).—The acidity which develops in olives after they are picked is due to a lipolytic enzyme which accelerates the hydrolysis of the glycerides into free fatty acids and glycerol with absorption of water. The activity of the lipase increases rapidly with the destruction of the cellular structure. The greater the initial acidity of the olives at the time of pressing, the more apt is the oil to be rich in lipase and develop more acidity. The acidity which develops in the oil is proportional to the water which remains emulsified during the process and also proportional to the glycerol already present. The glycerol, therefore, is the factor which governs the course and intensity of acid development, since it introduces water and lipase into the oil. PETER MASUCCI

Influence of bagging on the percentage of oil in castor beans. G. B. PATWARDHAN. *Poona Agr. Coll. Mag.* **22**, 13(1930).—Bagging castor bean flowers for seed propagation had no significant effect on the oil content of the seed. K. D. JACOB

The determination of the oil content of seeds in series. A. LEBEDYANTZEV AND N. DMITRIEV. *Masloboino Zhirovoe Delo* **1929**, No. 10, 3–10; No. 11, 3–9; No. 12, 9–17.—With the object of devising a method for serial detns. of oil in seeds L. and D. investigated the influence of various factors on the extn. of oils. After 4 hrs. of extn. 34.65% of the oil was obtained; after 18 hrs., 41.65%; and after 36 hrs., 41.76%. The usually specified time, 5–6 hrs. for extn. with a Soxhlet, is much too short; about 18 hrs. would be required for practical purposes. With 30 siphonings per hr. the extn. was complete in 16 hrs., as compared with 36 hrs. for 6 siphonings per hr. By pulverizing the material to a very fine state and with 30 siphonings per hr. the duration of the extn. can be reduced to 6 hrs. By previous maceration of the material with Et_2O for 18 hrs. the extn. time was reduced to 2 hrs. Up to 2 g. of a finely powd. material can be completely extd. within 6 hrs. at 30 siphonings per hr. Three g. of the material under the same conditions gave results which were lower by 1.1%. The Et_2O must be freed from alc. and dried over $CaCl_2$. To avoid the contamination of the Et_2O with H_2O the material should be dried at 100°. Drying oils should be dried in a N or a CO_2 atm. to avoid O absorption. Instead of drying, the material may be mixed with calcined $CaSO_4$. The best method for drying the extd. oil is to heat it in a N or a CO_2 atm. not over 60°. The oil content was detd. from the wts. of the extd. residues. The app., representing essentially an enlarged Soxhlet, was charged with 20 thimbles, each contg. 2 g. of material. The thimbles were allowed to soak for 24 hrs. in Et_2O and the extn. was carried out in 3 hrs. at 6 siphonings per hr. Uniform results were obtained agreeing within 0.16% with individual extns. in Teüge's app. The subsequent drying of the residues presents no difficulties, as it can be carried out by heating in the air at 100°. E. BIELOUSS

The relationship between acidity and titer of oils. I. STETZENKO AND I. PANTELEYEV. *Masloboino Zhirovoe Delo* **1929**, No. 10, 20–1.—Although the titer (*i. e.*, solidification point) of the fatty acids is higher than the titer of their glycerides, a high titer is no indication of a high acidity, as the neutral oil forms a eutectic mixt. with the free fatty acids. Thus a sunflower oil with an original acidity of 3.5% had a titer of 35.3° and 46.1° for the free acids. In admixts. up to 30% free acids the titer was below 35.3°. A hydrogenated sunflower oil with a titer of 56.4° and 61.6° for the free acids had a lower titer in admixts. up to 60% free acids. E. BIELOUSS

The splitting of oils and fats nearly to completion. G. PETROV AND A. PICHUGINA. *Masloboino Zhirovoe Delo* **1929**, No. 9, 53–6.—By the use of the naphthenic sulfonic acids oils and fats were hydrolyzed up to 97.87–99.6%. The hydrolysis was carried out in two steps by adding the sulfonic acids (0.9 to 1% of the oil) in two portions. E. BIELOUSS

Denaturing of protein of soy bean by alcoholic extraction. I. KOJI OKANO AND MANORU NINOMIYA. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co* **1929**, 7–9.—Alc. extn. decreases the H_2O-sol. and NaCl-soln.-sol., and increases the NaOH-sol. protein. No difference in the amino acids of the original and extd. products was found. V. F. HARRINGTON

Extraction of soy-bean oil with alcohol. II. 1. Solubility of soy-bean oil in alcohol. MASANORI SATO AND HIROSHI SAKAI. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co.* **1929**, 1–3.—The soly. of soy-bean oil in alc. of various concns.; in alc. dild. with C_6H_6, benzine or oleic acid; in MeOH; and in MeOH dild. with C_6H_6

has been detd. **2. Experiments on the extraction of soy-bean oil with alcohol.** MASANORI SATO AND MITSUO YOKOCHI. *Ibid* 3–6.—The optimum conditions are 2 extns. with alc. (96% by vol.) for 2 hrs. at 75° or above. The ext. cooled to 25° deposits the oil. Extn. above the b. p. gives better results. An app. is described. Yields are equal to those with benzine; the product is edible. **3. Separation and recovery of phosphatides and carbohydrates from the alcoholic extract.** MASANORI SATO AND IWAWO SETO. *Ibid* 6–7.—The residue from the alc. phase contains 27% carbohydrates, 1.27% N_2 and 1.07% P. Alc. dissolves the phosphatides. They can be coagulated by diln. of the alc. with H_2O and addn. of acid or salts. V. F. HARRINGTON

Determination of sandy matter in soy-bean cakes. SHUNICHI USAMI. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co.* 1929. 23–4.—The cake is shaken with CCl_4 and the sand weighed or measured in a flask similar to an inverted Babcock flask. V. F. HARRINGTON

The soy-bean oil from Kuban. M. SERGEEV. *Masloboino Zhirovoe Delo* **1929**, No. 3, 47–51.—Fifty-five samples of the 1927 crop were analyzed. The n_D^{20}, and the acid and I nos. of the Kuban oil are somewhat lower than the corresponding consts. recorded for the oils of different origins. The yield of beans per hectare depends on the vegetation period; it reaches 2250 kg. for the late crops (149–163 days). The oil content varies from 19.6 to 25.3%. E. BIELOUSS

Examination of Japanese beeswax. I. General properties. H. IKUTA. *Chem. Umschau Fette, Oele, Wachse u. Harze.* **38**, 7–10(1931); cf. *C. A.* **25**, 613.—I. examd. 8 Japanese beeswaxes, 2 of which were produced by native Japanese bees and 6 by the European bees which rapidly are displacing the native bees. The various kinds of honey-flowers have no relation to the consts. of the wax produced; the differences in Japanese and European waxes are due to the breed of bees. The compn. is greatly influenced by the kind of artificial comb employed. Waxes from native Japanese bees have: d_4^{10} 0.8168–0.8232; m. p. 64.5–65.5°; n_{40} 1.4557–1.4560; acid no. 7.5–5.4; ester no 75.6–79.2; sapon. no. 83.1–84.6; I no. (Wijs) 11.3–14.0; acetyl no. 20.7–18.7; unsaponifiable constituents 58.3–56.5%. Only 2 of the other 6 samples were considered pure wax (European type of bees): d_4^{10} 0.8141–0.8132; m. p. 62.0–63.5°; n_{40} 1.4554; acid no. 19.8–19.4; ester no. 74.0–74.1; sapon. no. 93.8–93.5; I no. (Wijs) 8.5–7.2; acetyl no. 13.1–14.4; unsaponifiable constituents 49.5–48.6%. In addn. I tabulates the consts. of the saponifiable constituents of the waxes, their alcs and their hydrocarbons. P. ESCHER

Manganese soaps. HANS WAGNER AND G. HOFFMANN. *Farben-Ztg.* **36**, 689–93 (1931).—The reaction of umber with linseed oil fatty acids was studied by exposing mixts. of umber and fatty acids to ultra-violet light, daylight and darkness. The samples were exposed on microscope slides with and without cover glasses. In all cases where crystn. took place, ether-sol. Mn compds. were found, but the formation of Mn soaps was not definitely proved. Pronounced crystn. took place only in the presence of oxidizing or catalytic compds. Thus pyrolusite produced no crystals, but several ter- and quadrivalent Mn compds. did so as a result of the O_2 liberated in the reduction of the Mn to the bivalent form. G. G. SWARD

Analysis and preparation of medicated soaps. G. MATOLCSY. *Magyar Gyógyszerésztud. Társaság Értesitöje* **5**, 489–502(1929).—The flame reaction of soaps may show what alkalies have been used in their prepn. Color, odor and consistency should be observed. The water content can be measured on the basis of the resistance against cutting. The paste-cutting machine of Rejtö has been used for this detn. Fatty acids, content of alkalies, and org. and inorg. filling materials are detd. according to standard methods. A short description of the prepn. of medicated soaps is given. S. S. DE FINÁLY

Combinations of raw materials for toilet soap. BUNJI NAKAGAWA. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding 22–7, 28–31(1931).—Soaps of 8 different oils were mixed in proportions of 10–80% with a soap consisting of 80% Na tallow soap and 20% Na coconut-oil soap and the lathering no. (L. N.), lathering vol. (L. V.), lathering coeff. (L. coeff.) and rate of lather extinguishment detd. L. coeff. = L. N. × L. V., and the rate of lather extinguishment = {[(L. coeff. at 1 min. after shaking) − (L. coeff. at 5 min. after shaking)]/(L. coeff. at 1 min. after shaking)} × 100. Na palm-oil soap (I) has a good effect upon lathering. Hardened soy-bean oil soap (II) of 67.7 I no. has a better effect at 40° than at 20°, where it shows a reverse tendency. A Na lard soap (III) has a good effect on the L. coeff. at the start, but the rate of lather extinguishment rises with the increase in amt. of this soap. A 40% mixt. is the best for lathering power. Na hardened fish-oil soap (IV) decreases the L. coeff. The Na soap (V) of Chinese

vegetable tallow has not much effect on the L. coeff., but the rate of lather extinguishment is larger. At 20° the L. coeff. decreases. Na castor-oil soap (VI), Na peanut-oil soap (VII) and K tallow soap (VIII) all have a good effect upon the lathering, but VI is the most desirable. The soly of mixed soap was measured in an attrition app. composed of an endless rubber band rotating at 1086 cm. per min. and dipping into a water bath at 40° and 20°. A soap cake 2 × 3 × 2 cm. was fastened and weighted with 135 g. so that the rubber band could rub it. The duration of the operation was 10 min. at 40° and 20 min. at 20°, and by weighing back the soap the attrition was detd. The degree of attrition is designated "rubbing soly." and is calcd. by the formula: rubbing soly. = 100 × [soap by attrition (g.) ÷ rubbing surface (cm.²)]. The rubbing soly. of Na tallow soap mixed with 20% Na coconut-oil soap is smaller than that of the former alone but increases with increase of the latter. The mixt. with I or II does not increase the rubbing soly. In the mixt. of III the rubbing soly. increases with increase in amt. of this soap; in mixts. of IV it decreases with increase of this soap. In the case of V the rubbing soly. tends to decrease, and this effect is greater at 20° than at 40°. A 2.5% mixt. of VI increases the rubbing soly., as do also VII and VIII, 15% of VII being equal to 2.5% of VI. The relative hardness of the mixed soaps was detd. from the distances 2 5-cm. metal points 2 and 3 mm. in diam. (weighted to a total of 300 and 600 g., resp.) penetrated into the soaps, a homogeneous curd soap being the standard of comparison. The hardness of mixed Na tallow and Na coconut-oil soap increases with the increase in the amt. of the latter until, with 40% coconut-oil soap, the soap is unsuitable for toilet use. I and II (I no. 67) have a tendency to soften the mixed soap, I having a greater effect than II. IV (I no. 22.3) in lower percentages produces a slight softening in the mixt., but when 50% is used, it hardens the product V increases the hardness as its amt. is increased VII, VIII and VI (effective in this order) soften the mixt. according to the amts added. Conclusion: palm oil, hardened soy-bean oil and Chinese vegetable tallow can generally be used as substitutes for tallow, and the most desirable for the combination are castor oil, peanut oil and the K soap of tallow

E. Scherubel

The utilization of soap lyes. S. Liberman and A. Korelskii. *Maslobojno Zhirovoe Delo* **1929**, No. 6, 21–5.—The soap lyes, left after the salting out of the soap base, contain about 1.3% NaOH and 0.5% Na_2CO_3. L. and K. recommend their recovery by treatment with free fatty acids and rosin. E. Bielouss

Actual problems in the manufacture of washing compounds. J. Leimdörfer *Seifensieder Ztg.* **57**, 869–72(1930).—L. discusses the economic and mfg. phases of toilet, laundry and soft soaps. The brown spots on cottonseed-oil soaps may be prevented by hydrogenating the oil to lard consistency or by polymerizing it at 260–280° for 5–6 hrs. in a CO_2 atm. before sapon. P. Escher

Ambergris and how to recognize it. F. R. Morrison *Bull. Tech Museum Sydney* No. **15**, 9 pp.(1929).—The different varieties of ambergris are described, together with their values, uses and characteristics. All ambergris will float on sea water, and if the latter is slowly heated, the material will melt to a brown or black liquid before the water reaches its b. p. A piece of ambergris about the size of a pea is almost completely sol. in about $^1/_2$ oz. of warm alc., giving a fluorescent soln. A needle, previously heated in a candle flame for 10–20 sec., on being pressed into a sample of ambergris to a depth of $^1/_8$ in., forms a dark brown resinous liquid which, when touched by the finger, leaves pitch-like "strings" adhering to the skin. If the needle be withdrawn and placed in the flame, the ambergris burns; if the flame be extinguished the odor of the "smoke" is somewhat fatty or resinous and resembles that of burning rubber

Oiticica oil (Sward) **26**. Insect oils and fats (Timon-David) **11I**. Value of ash determinations of fatty oils (Schaeffer) **22**.

Apparatus for washing and mixing fats and waxes having the consistency of butter. Richard Bendlin and Ottokar Urbasch. Fr. 692,687, Jan. 6, 1930.

Coloring higher fatty acids such as stearic acid. Hermann Schladebach and Herbert Hähle (to General Aniline Works). U. S. 1,791,431, Feb. 3. A coloring substance such as a thioindigo and an amino compd. such as triethanolamine are added to fatty acids while the latter are in liquid state. Numerous examples of use of Cu salts, etc., also are given.

Extracting oils and fats. Sträuli & Cie. (Ernst Müller, inventor). Ger. 515,058, July 20, 1926. This relates to the extn. of oils and fats from oil seed press cakes, used bleaching earth and like residues. The material is ground and mixed with

a solid diluent, *e. g.*, sawdust, and the mixt. is lightly pressed into briquets which are then extd. with a solvent in known manner.

Apparatus for extracting oils from seeds, sewage or other materials by solvents. CLARENCE J. BLEIL. U. S. 1,791,398, Feb. 3. Various details are described of an app. comprising an endless filter made up of connected sections. Cf. *C. A.* **24**, 1257.

Recovering dry palm oil from its admixtures with water. JAMES H. HOLDEN and JOSHUA C. WHETZEL (to American Sheet and Tin Plate Co.). U. S. 1,790,748, Feb. 3. A water-in-palm oil mixt. sepd. from a palm oil-in-water emulsion formed by washing palm oil from tin plate, after it passes from the tinning pot, is heated until substantially all the water is vaporized; the mixt. of oil and vapor resulting from the heating is then delivered into a draft of air of sufficient velocity to carry away the vapor and of insufficient velocity to pick up the oil. App. is described. Cf. *C. A.* **24**, 3749.

Soap. PIERRE P. A. CHAPELLE. Fr. 693,580, April 9, 1930 A soap for domestic use or for mechanics contains tallow soap 50, fine white pumice 43, glycerol 5 and resin 2%

Soaps, creams, etc. SOC. D'ÉTUDES SCIENTIFIQUES ET INDUSTRIELLES. Fr. 692,454, June 19, 1929. Biol. products are used in soaps, creams, etc. Fr. 692,455 describes the use of exts. from fungi etc., in soaps, creams, etc.

28—SUGAR, STARCH AND GUMS

J. K. DALE

Electrical conductivity and ash content of sugar house products. K. ŠANDERA. *Bull. assoc. chim. sucr. dist.* **47**, 446–9(1930).—A new app. is described for the electrometric detn. of ash in which Pt-black electrodes are eliminated An optical method is used to det. the end point instead of a galvanometer. The app. is in principle a Wheatstone bridge. Two of the 4 resistances are lamps, the light of the lamps falling on the surface of a triangular prism. The bridge is balanced when the 2 lamps appear to be of equal brightness. The prism reflects the light from both lamps onto the field of vision, thereby facilitating comparison. The third resistance is a const. and the fourth is a variable resistance consisting of the sugar soln. with 2 electrodes. The distance between the electrodes is variable and is changed to balance the bridge. The distance apart may be calibrated to read ash content. F. CAMPS-CAMPINS

The action of nonsugars in sugars upon the caramelization test. J. PUCHERNA. *Listy Cukrovar.* **49**, 13–20(1930).—Thin-walled containers contg. 6.5 g. of a sugar mixt. were dried at 100° for 2 hrs. The containers were then submerged in an oil bath at 170° for 15 min., withdrawn and cooled in the air The residue was dissolved in 50 cc water, filtered and compared in an objective photometer. The remaining soln. was treated with 0.5 cc. 2 *N* NaOH, digested over a water bath for 10 min., cooled and compared in the photometer for additional coloration. The action of salts falls into 3 classes: (1) large primary and small secondary coloration, (2) small primary and large secondary coloration, (3) very little coloration. Salts falling into class (3) are NaCl, KCl, $BaCl_2$, K_2SO_4, Na_2CO_3, AcONa, $AcONH_4$, Na oxalate. All salts in this class except $AcONH_4$ are strongly electropositive and their solns. are neutral or alk. The small coloration in alkali formed by the chlorides and acetates indicates a decompn. of sucrose into glucose and fructose which readily give rise to colorations. Acetates form more primary coloration than chlorides. Sucrose in soln. and at high temps. behaves as an acid. At 170° AcOH is volatilized from AcONa by sucrose. The sucrose liberates an equiv. quantity of an acid from the salt of the acid. The action is most pronounced for weak acids; the resulting soln. is alk., which favors a decompn. of sucrose. For NaCl, KCl and $BaCl_2$, the liberated HCl is small, the medium is neutral and no decompn. due to increased alky. occurs. $AcONH_4$, as the salt of a weak acid and base, remains neutral in action. Na_2CO_3 leaves an alk. medium, and some coloration results. K_2SO_4 decomposes at 1050°; it cannot be attacked by the sucrose and remains neutral during the decompn. Na oxalate behaves more like NaCl than AcONa. $(COOH)_2$ is a stronger acid than AcOH and the decrease in coloration agrees with their dissocn. consts. Class (1) consists of salts or amides of amino acids. Metallic salts of amino acids have a greater effect than the corresponding amides because of the action of the alkali. Class (2) forms products which become colored in alkali. NH_4Cl, $Fe(NH_4)_2(SO_4)_2$, NH_4 oxalate and $(NH_4)_2SO_4$ cause a large primary coloration in addn. to the secondary; $CaCl_2$, betaine-HCl and glutamic acid-HCl give very little primary coloration; $Fe_2(SO_4)_3$ and $KHSO_4$ lie between these groupings.

Betaine-HCl decomposes at 228°; glutamic acid-HCl, at 208°; in the presence of sucrose the decompn. begins at a lower temp. The effect of sucrose upon salt is marked: HCl is liberated and attacks the sucrose, forming invert sugar. The additional coloration in an alk. medium is a linear function of the catalytic salt. Too much acid, 0.2%, causes a more thorough decompn. with the production of ulminic acid and caramelin. $CaCl_2$, although similar to $BaCl_2$, acts as a strong dehydrating agent and falls into class (2). The larger primary coloration with Na_2SO_4 and $Fe_2(SO_4)_3$ is due to the dehydrating and oxidizing action of H_2SO_4. The large primary coloration with NH_4Cl, $(NH_4)_2SO_4$, NH_4 oxalate and $FeSO_4.(NH_4)_2SO_4$ is due to the action of NH_4 on sucrose; with NH_4Cl, the action of NH_3 exceeds that of HCl. The class (2) catalysts form a fluid mixt. very soon after heating; larger addns. cause foaming with intense odors suggesting C_6H_5CHO. The solns. become acid. Sucrose may act as a solvent for salts capable of dissocn. Granules of salts are often surrounded by a low-melting mixt. which contains sucrose in a fluid state. The sucrose may exert its high dielec. properties as a solvent; the dissocn. of salts in this "sucrose solvent" is similar to dissocn. in water. A mixt. of salts in the form of molasses was also tried. The effect is complicated not only by the presence of mixed salts but also by the colored org. substances of molasses whose effects have not been studied. The primary coloration with molasses is large; the secondary is small; the effect is due primarily to substances of class (3). FRANK MARSH

Iodometric determination of sugar. M. S. FILOSOFOV. *Nauk. Zapiski Tzukrovoi Prom.* 9, 586–9(1930).—In certain cases the sucrose cannot be detd. polarimetrically. The following method may be used on molasses. The normal wt. of molasses is dissolved in water to 130 cc. Fifty cc. of soln. (10 g. of molasses) is transferred into a 100-cc. flask and 25 cc. of H_2O contg. 5 cc. of HCl (d. 1.19) is added The inversion is conducted according to the Herzfeld method. The soln is made up to the 100-cc. mark and thoroughly mixed. Twenty cc. of the inverted soln. is transferred to a 400-cc. flask, 20 cc. of Na_2CO_3 soln. (84 g. per l.), 1–2 cc. of lead acetate and the same amt. of $Al(OH)_3$ are added. The excess of lead acetate is eliminated with soda ash and the whole made up to the 400-cc. mark and filtered. Fifty cc. of filtrate is transferred into a 250-cc. Erlenmeyer flask. Four to five g. of pure sucrose, and 50 cc. of Fehling soln. are added. The mixt. is boiled for 2 min. and then cooled by addn. of 100 cc. of H_2O, transferred to a 250-cc. flask and made up to the mark. One hundred cc. is transferred to an Erlenmeyer flask, 5 cc. of a soln. contg. 0.65 g. KCNS + 0.1 g. KI in 5 cc. of water, is added and thoroughly mixed. Ten cc. of 6.5 *N* H_2SO_4 is added, mixed and titrated with 0.1387 *N* $Na_2S_2O_3.5H_2O$. Five cc. of 1% starch soln. is added as indicator. The Brunce table gives mg. of invert sugar and this multiplied by 0.9 gives the sucrose Cf. *C. A.* 24, 985. V. E. BAIKOW

A preliminary study of the glucose, sucrose and refractometer solids relationships of five sugar cane varieties grown under Laguna conditions. MANUEL L. HOLLERS. *Philippine Agr.* 19, 299–305(1930).—The sucrose content varies widely in different parts of the plant. The refractometer solids vary directly with the gravity purity. In all varieties the refractometer solids and gravity purity decrease and the glucose content increases from the bottom to the top of the plant. A. L. MEHRING

The relation between the ash content of raw sugar and the conductivity of sugar solutions of different concentrations as well as of acidified sugar solutions. O. SPENGLER AND F. TÖDT. *Z. Ver. deut. Zuckerind.* 80, 853–65(1930).—Expts. on some 60 samples of German raw sugars show that the elec. detn. of ash is more accurate at 5° Bx than at a higher Bx (*e. g.*, 25°Bx). The correction factor of Zerban for the decrease of the difference between the chem. and the elec. ash detn. was applied to 70 samples of German raw sugars. The results were inadequate. This shows that the non-sugars in the samples tested by Zerban are different from the non-sugars in the German samples. F. CAMPS-CAMPINS

The Kämpf viscometer. ERHARD LANDT. *Z. Ver. deut. Zuckerind.* 80, 949–55 (1930).—A description is given and the method of operation of the app. is reviewed. Tests were carried out on various sugar solns. Conclusion: It is sufficiently accurate for solns. of viscosities over 3 poises. (There is no turbulent flow above this value.) It is especially recommended for solns. of high viscosity. The instrument will work even where solid suspended particles are present. The viscosity in this case is, of course, not the same as the viscosity of the pure liquid (cf. *C. A.* 24, 1767). F. C.-C.

The determination of reducing sugars in the presence of sucrose by potassium ferricyanide. R. HAMY. *Bull. assoc. chim. sucr. dist.* 47, 385–7(1930).—The method of Jonescu and Vargolici (cf. *C. A.* 15, 3564) is reviewed. Comparative tests were made on sugar solns. with varying contents of sucrose. It is shown that $CuSO_4$-Rochelle salts methods give results which are too high, increasing with increasing amts. of sucrose

For the J. and V. method the true result is obtained as long as the sucrose content is below about 30%. The end point is quite sharp. F. CAMPS-CAMPINS

The continuous recording of the alkalinity of saturation beet juices by conductivity measurements. O. SPENGLER AND F. TÖDT. *Z. Ver. deut. Zuckerind.* **81**, 1–12 (1931).—The alky. tester of Reinhard Lindner which gives a continuous indication and record of the alky. by cond. measurement was tested in a factory. Such control seems feasible for continuous satn. A conclusive decision is possible only after further investigation, but a straight-line relationship is indicated. The influence of juice compn. on cond. needs to be studied. F. CAMPS-CAMPINS

The Šandera objective photocolorimeter. ALOIS DOLINEK. *Listy Cukrovar.* **49**, 203–5(1930).—Using various liquors available in a refinery, D. compared the Stammer and Šandera photocolorimeters. The av variation in readings with the Stammer was 3.5–5 times as great as with the Šandera colorimeter. The variation of eyes is insignificant with the Šandera colorimeter, but large with the Stammer. F. M.

Effect of certain non-nitrogenous substances on the polarimetric determination of sugar. E. PARISI. *Ind. saccarif. ital.* **23**, 217–9(1930); *Chimie & industrie* **24**, 1202 (1930).—P. shows that the polarimetric detn. of sugar can be vitiated by soln. of foreign substances derived directly or otherwise from pectin. Heating dried beet pulp with distd. water on the water bath gives a strong *d*-rotatory soln., because of the presence of arabinose (arabinose anhydride), which is partially pptd. by basic $Pb(OAc)_2$; if $Ca(OH)_2$ water is used instead of distd. water, the soln. is strongly *l*-rotatory on account of the presence of Ca or Mg salts of pectic acid; if a soln. of basic $Pb(OAc)_2$ is used, the soln. is much less *l*-rotatory. A. PAPINEAU-COUTURE

Determination of the amount of crystal in massecuites by the electrical conductivity method. K. ŠANDERA. *Z. Zuckerind. Cechoslovak. Rep.* **54**, 361–4(1930).—In place of calcns. based on formulas employing the dry substance or polarization of the massecuite, elec. cond. measurements afford a more reliable method for the calcn. of the amt. of crystal to be expected, and are besides considerably more expeditious. B. C. A.

Analysis of sugar cane. E. HADDON. *S. African Sugar J.* **14**, 675(1930).—Sucrose in cane is usually estd. by multiplying sucrose in juice by a factor which necessarily varies with the proportion of juice in cane. H. proposes to det. sucrose % cane directly by repeatedly extg. on a Buchner funnel 100 g. of finely disintegrated cane, neutralized by means of lime water, with hot water until a total vol. of 1000 cc. is obtained. The ext. is clarified, polarized in a 400-mm. tube, and the result multiplied by 1.3. To obtain juice % cane, a quantity of the pulp is pressed in a tincture press; the extd. juice is clarified and polarized, and its sp. gr. is detd. Then juice % cane = 100 sucrose % cane/sucrose % juice. The quantity (100 − juice % cane) is termed marc, which is the hydrated insol. part of the cane. The water % cane is detd. by drying the pulp. The fiber % cane is then found by subtracting from the marc the difference between water in cane and water in juice. Six typical analyses are given, showing that the fiber % cane detd. by lixiviation is considerably lower than that found by H.'s method. F. W. ZERBAN

Determination of fiber and sucrose in cane. M. BECHARD. *S. African Sugar J.* **14**, 743(1930); cf. preceding abstract.—Haddon's article is criticized. The inaccuracies inherent in cane sampling may lead to errors of 2 units in the % fiber. Even if a correct sample of pulp can be obtained the analysis should be made by pressing the pulp, analyzing the juice for Brix and sucrose, and the residue for water and sucrose. From these figures the sucrose and fiber % cane can be calcd. directly. H.'s methods are based on incorrect assumptions, and the results for fiber will be accurate only within −2.4 and +5.4 units. H.'s figures actually show errors of this magnitude, as the water held by the dry fiber varies in his results from 31.8 to 86.2%. The problem of fiber detn. in cane has not yet been solved satisfactorily. F. W. ZERBAN

A new spectral colorimeter. O. SPENGLER AND E. LANDT. *Z. Ver. deut. Zuckerind.* **81**, 13–24(1931).—A detailed description and method of use of the app. are given. In principle it is like a Duboscq colorimeter equipped with a monochromator. Readings are made at λ = 610, 560 and 480. Exptl. figures show the accuracy of the instrument when used as a Stammer-app. in the broader sense and also for the comparison of 2 colored solns. In the latter case $\alpha_1/\alpha_2 = c_2h_2/c_1h_1$, where α is the extinction coeff. at the given wave length, c the concn., and h the height of the liquid column. F. CAMPS-CAMPINS

Apparent disagreement in the analysis of molasses. J. J. WEISS. *Listy Cukrovar.* **49**, 213–4(1930).—The molasses of the present season have been very dark and have

led to discrepancies in analyses. All discrepancies have been due to improper sampling of molasses for analysis. Studies in sampling are in progress. FRANK MARESH

Materials for the study of sucrose crystallization. I. A. KUKHARENKO AND I. N. KAGANOV. *Nauk. Zapiski Tzukrovoi Prom.* **9**, 492–9(1930).—The rate of crystn. has the highest velocity during the seeding at the beginning of the process. The max. speed of crystn. does not exceed 10,000 mg. on 1 sq. m. of crystal surface per min. One hr. from the moment of the seeding is required to obtain crystals of 1 mm. length. For a sugar crystal of an ordinary kind the approx. size is: $P = 0.35\ L^3$ and $S = 2\ 1\ L^2$, where P is the wt. of the crystal in mg., S its surface in sq. mm., and L its length in mm. V. E. BAIKOW

Influence of bagasse analysis on the sucrose content of the cane. E. HADDON. *S. African Sugar J.* **14**, 741(1930).—Previous investigators have shown that prolonged boiling and greater diln. increase the polarization of the bagasse ext. This is probably due to the extn. of optically active non-sucrose substances derived from the hydrolysis of hemicelluloses. To prevent this, the extn. must be carried out in the presence of $Ba(OH)_2$, alky. to phenolphthalein being kept up until the end of the digestion. The baryta method applied to bagasse gave results 0.08 to 0.33% lower than the ordinary method. F. W. ZERBAN

The deterioration of Philippine sugars under varying degrees of humidity. QUERINO D. RENDON. *Philippine Agr.* **19**, 383–96(1930). -Increase of H_2O in cane sugar favors rapid growth of organisms, which causes the sugar to deteriorate and introduces an error in the polarimetric detn. of sucrose. The max. degree of humidity in which sugar will not deteriorate is 66.2%. In an atm. of 100% relative humidity 36% of the sugar was lost in 4 months. A. L. MEHRING

Adsorption from sugar solutions. III. Adsorption in the carbon layer with acetic acid. J. VÁCHA AND J. VAŠÁTKO. *Listy Cukrovar.* **49**, 171–5(1930). -Activated charcoal which has the slowest filtration time shows the greatest no. of small grains and possesses the greatest surface and internal condensation of water vapors. With 10 g. of charcoal in a 50-cc. filter, H_2O at 20°, $p_H = 7.2$, and a head of pressure of 208 g. per sq. cm., the increasing order of filtration is: Supra-norit 5x, Supra-norit 3x, Carboraffin, Radit, Supra-carboraffin, Polycarbon, standard norit. The rate of flow of H_2O through the charcoals varies exponentially with the pressure. Changes in temp. alter the viscosity of H_2O. At higher temps. (85°), a rapid flow occurs during the first stage of filtration; the process of wetting the surfaces and packing of layers proceeds slowly at higher temps. The rate of flow through charcoal decreases with increased viscosity of sugar solns.; the degree of coloring had no effect upon the rate of flow. Adsorption of CH_3COOH occurs very rapidly during the first addns. of CH_3COOH. Satn. was attained when 1 l. CH_3COOH (1 818 g. per 100 cc.) was used per g. of charcoal. FRANK MARESH

The results of sampling raw sugar. JIŘÍ VONDRÁK. *Listy Cukrovar* **49**, 175–80 (1930).—A survey of the result of using standard methods of prepg. representative samples during the seasons of 1927–30 is reported. FRANK MARESH

The treatment of the after-liquors. G. DIEHN. *Listy Cukrovar.* **49**, 181–2(1930). -The diln. water was computed on the basis of non-sugars present in raw sugar juices and added while the digested liquor was being released. During the outflow, an analysis was made, and the final diln. was made during the entrance into refrigerators. Samples of computations are given. FRANK MARESH

The course of the first saturation. III. Reproducibility of the saturation with lime and sugar solutions. J. DĚDEK. *Listy Cukrovar.* **49**, 183–90(1930).—App. used in previous expts. were not capable of maintaining identical conditions throughout the course of the whole expt.; the accuracy of the previous observations and conclusions is lowered. Further observation of the satn. process in plants showed that it is more complicated than lab. findings indicated. Using a highly refined app. with precise controls, D. ran over 100 expts. with pure sucrose and CaO from marble and observed total alky., alky. of the filtrate, absorption of CO_2 and elec. cond. Detailed curves are thoroughly discussed. Although the curves show great similarity, D. was not able to attain an abs. reproduction under the refined method used, especially in elec. cond. Curves of changes of alky. at 20°, 50°, 70°, 90° do not resemble those of elec. cond. at the same temp.; at higher temps. elec. cond. curves show 2 characteristic transformation maxima. In some instances the elec. cond. continued to diminish markedly even after abs. neutrality had been attained. This is due to a delayed hydration of CO_2 and changes accompanying the formation of sediment. The $CaCO_3$ comes out of soln. in a "firm form" more slowly than when it is formed by neutralizing CaO with CO_2 in satd. or supersatd. solns. **IV. The union of lime in sediments.** K. KOBLIHA AND

E. PALEČEK. *Ibid* 199–203.—The suspensions of $CaCO_3$ or CaC_2O_4 which form in a sucrose-CaO soln. retain some of the free CaO. The concn. of CaO in the sediment depends upon the alky. of the filtrate, *i. e.*, upon the actual concn. of CaO in soln. This dependence has the form of an adsorption isotherm. The removal of CaO from the sediment is very rapid during the first 0.25–0.5 hr.; the remainder is not released completely during the next 48 hrs. K. assumes that the CaO in suspensions is in 2 states: (1) CaO which is immediately sol.; (2) CaO which becomes sol. after the first is dissolved. When oxalates were suspended in a CaO-sucrose soln., CaO was removed from soln.
F. M.

How much non-sugar from the water used for diffusion passes into the juice [in beet-sugar factories]? V. STANĚK AND J. VONDRÁK. *Z. Zuckerind. cechoslovak. Rep.* **54**, 117–21(1929).—The water supplies of some beet-sugar factories are liable, at times, to contain abnormal amts. of dissolved solids. To ascertain what proportion of the dissolved solids in the water passes into the juice the authors carried out comparative diffusion expts. with a lab battery, using distilled water alone and distilled water contg. 0.1 and 0.5% of NaCl and urea. From the amts. of these substances found in the diffusion juices it is concluded that about 1/4 of the dissolved matter in the water passes into the juice. If this is not removed by carbonatation, it must lower the purity of the final juice and increase the amt of molasses obtained The extra molasses due to 0.1% of mineral salts or 0.1% of org non-sugar in the original water may amount to 0.25% of the wt. of beets in the former case or 0.12% in the latter. B. C. A.

The influence of invert sugar upon the removal of amino acids from sugar solutions during saturation. VÁCLAV KONN *Listy Cukrovar* **49**, 190–5(1930).—The presence of a mixt. of glucose and fructose decreased the amino N removed with the sediment. Controls made without the invert sugar but with increasing CaO content also increased the amino N in the sediment. Glutamic and aspartic acids, asparagine and leucine were studied The removal of the amino acids depends upon the presence of physically active CaO, *i. e.*, lime which forms $CaCO_3$ during satn. and carries the amino acids into the sediment by adsorption. FRANK MARESH

The balance of analysis of beet juices. FERDINAND KRYŽ. *Listy Cukrovar.* **49**, 195–8(1930).—Pressed juice from beet roots is not identical with the natural beet juice; the pressed juice contains natural beet juice secreted by the cells and admixts. of juices from cell walls and interstitial tissues FRANK MARESH

Scale from (sugar-house) evaporators. E. SAILLARD. *Circ. hebd. comité central fabr. sucre* **42**, 627(1930); *Chimie & industrie* **24**, 1205–6(1930).—Analyses were made of 93 samples of scale after a season's run All contained CaC_2O_4 in variable amts., also insol. SiO_2 and sometimes Ca silicate, the latter being probably produced in the lime kiln because of excessive heating. There is generally 1–2% $CaSO_4$ originating from the limestone or from sulfitation. The amt. of $CaCO_3$ varies according to the efficiency of the boilers in decompg. and pptg. bicarbonates. The Fe_2O_3 and Al_2O_3 content decreases from the 1st effect (40%) to the last effect (about 1%); they originate chiefly from the limestone and coke. The points to be watched in order to reduce scaling are: the compn. of the limestone, the alky. of the juices before boiling, the operation of the boilers and of the evaporators, the concn. of the wash liquors and the time of washing.
A. PAPINEAU-COUTURE

The importance of a preliminary purification of the diffusion juice (beet). I. B. MINTZ AND B. E. KRASIL'SHCHIKOV. *Nauk. Zapiski Tzukrovoi Prom.* **9**, 515–37(1930).—Russian kieselguhr was compared with the best American and German grades and was found very much alike except for the wt which is 3–4 times higher and the proportion of large particles is much greater. The filtration of diffusion juice through asbestos or fibrous material is advisable. The amt. of total N in carbonation juices, obtained from diffusion juices previously boiled or treated with 0.5–1.0% of kieselguhr, is 9–12% lower than that in ordinarily treated juices. The color of the juices at high alky. is the same; at lower alky. (0.02–0.01) the coloration of the preliminary treated juices is considerably lower than the color of juices treated in the usual way. Good clarification of the juice is obtained by preliminary sulfitation to a p_H of 4.0 at a temp. of 20–40° followed by neutralization to alky. of 0.1 with lime and increasing the temp. to 80°, then further filtration and carbonation to an alky. of 0.01–0.02. V. E. B.

Hyposulfites, redos, sulfoxylates and oxymethanesulfines. M. MESTRE. *Bull. assoc. chim. sucr. dist.* **47**, 388–93(1930).—Based on his experience with hyposulfites, M. concludes that the Teatini process is sound as is indicated by the ultramicroscopic study of the colloids. The chemistry and application of sulfoxylates and hyposulfites are briefly reviewed. Oxymethanesulfine is entirely different from the others and is not used in the sugar industry. F. CAMPS-CAMPINS

Return of greens and molasses into diffusion battery. I. B. Mintz, G. S. Benin, A. K. Kartashov and B. E. Krasil'shchikov. *Nauk. Zapiski Tzukrovoi Prom.* 9, 399–431(1930).—Expts. on returning greens and molasses to diffusion juice continuously or intermittently proved unsuccessful. The total losses increased from 2.61 to 3.31%. The yield of final molasses increased and more fuel was used. The purity of the juices and sirups decreased. The expts. were run in different beet-sugar factories with practically the same results. V. E. Baikow

The investigation of the incrustation from the juice heater. I. O. Trefil'ev and S. A. Kostro. *Nauk. Zapiski Tzukrovoi Prom.* 9, 432–49(1930). V. E. B.

Investigation of the conditions for increasing the velocity of crystallization in "sugar loaves." M. I. Nakhmanovich and I. F. Zelikman. *Nauk. Zapiski Tzukrovoi Prom.* 9, 450–92(1930).—A no. of expts. in different refineries in Russia showed that velocity of crystn. in sugar loaves greatly increases with a sharp decrease of the temp. The most convenient temp. in the cooling rooms is +5°–+10°. In summer the low temp. can be maintained with the aid of ventilating fans. The increased rate of the cooling does not affect the quality of the refined sugar. The hardness and the color of the latter remain practically the same as during the cooling of the sugar loaves at the higher temps. The bleaching of the sugar is normal. A no. of tables and diagrams are included. V. E. Baikow

Boiling of a refinery massecuite with low-pressure steam. I. F. Zelikman. *Nauk. Zapiski Tzukrovoi Prom.* 9, 506–14(1930).—The excess of low-pressure (1–2 atm.) steam was used for boiling refinery massecuite. The increase in the time of boiling caused a slight increase in reducing sugars and coloring matters. These difficulties can be overcome by using a vacuum pan with a larger heating surface. V. E. Baikow

The bleaching effect of washing the massecuite of the second skip. V. V. Cheshchevik. *Zhur. Sakharnoi Prom.* 4, 305-8(1930).—The following expts. were made to det. the increase in yield and quality of white sugars resulting from the second skip. The massecuite was washed (*A*) with greens of 30° Bé., (*B*) with hot final molasses, and (*C*) with a measured quantity of molasses at 90–95° (3.4–5.0% on the wt. of massecuite), followed by warm water (1.8–2.0% on the wt. of massecuite). In (*A*) the yield of yellow sugar decreased 9.5%, with purity increase of 0.9%, while color decreased 47.9% and the time of centrifuging decreased 19.2%. In (*B*) the yield of the yellow sugar decreased 1.5% with a purity increase of 0.9%, and the color decreased 23.1%. Purity of the molasses increased 0.5% and centrifugal time decreased 10%. In (*C*) the yield of the yellow sugar decreased 9.2%, while its purity increased 3.7%, color decreased 83.7% and the centrifugal time decreased 25%. Obviously method *C* is the most advantageous. V. E. Baikow

Cane sirup manufacture. J. O. Carrero. *Porto Agr. Expt. Sta.* **1929**, *Rept.* 13–4 (1930).—A light-colored sirup of full, agreeable flavor was manufd. from sugar cane. The juice was readily clarified with H_3PO_3 and CaO but considerable sediment was formed during storage. The use of CaO always darkened the sirup. By restoring the cane juice to its original acidity after clarification, a better color was obtained. C. R. Fellers

The beet crop in Czechoslovakia for 1930. Jaroslav Souček. *Listy Cukrovar.* 49, 207–12(1930).—The sugar crop was above normal; the sugar content was normal; the total yield is estimated at 62.7×10^6 q. of beets and 11.1×10^6 q. of sugar. Frank Maresh

A study of the biology of the beet-nematode, Heterodera Schachtii Schm. M. Sinitzkii. *Nauk. Zapiski Tzukrovoi Prom.* 9, 538–44(1930). V. E. B.

The physical and chemical properties of kaoliang starch. I. The adsorption of iodine and chlorine by kaoliang starch. Shoji Kiki. *Abstract from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 24–6.—The absorption of I and Cl is represented by the Freundlich equation, $x = kc^n$, in which x is the quantity adsorbed and c is the concn. of the Cl or I soln. A break in the curve of log c *vs.* log x probably represents a change in surface tension due to swelling of the starch granule. V. F. Harrington

Polarimetric determination of starch in potatoes and the relation between potato-dry substance and starch content. Carl von Schéele. *Medd. Kgl. Lantbruksstyrelsen* 1930, No. 283, 5–14.—Behrend, Maercker and Morgen (*Landw. Vers. Sta.* 25, 1880) detd. the relation between the sp. gr. of potatoes and the starch content, and prepd. a table, which has not been used widely, and which contains errors. The relation between potato dry substance and starch content was found to be practically const. at 5.75. The accuracy of the starch detn. was ±2%, attributed to air spaces. For starch detn. 3 g. of air-dried, finely ground potato heated with 50 cc. of H_2O for

4 hrs. at 135–40°, cooled to 90°, filtered from undissolved residue, washed with boiling H_2O, the filtrate dild. to 200 cc., and digested with 20 cc. HCl for 3 hrs. on a water bath, cooled, almost neutralized with KOH, 7–8 cc. of $Pb(OAc)_2$ added and dild. to 500 cc., 200 cc. removed and 50 cc. of 1% H_2SO_4 added to ppt. Pb, and sugar detd. in the filtrate with Fehling's soln. Dry substance was detd. by the Holdefleiss method (Über die Werthbestimmung der Kartoffeln. Landwirtschaftliche Jahrbücher 1877, Supplementheft, 107). The dry substance of potatoes contains pectin, which hydrolyzes under pressure to arabinose and galactose, which are detd. as sugar, giving high values for starch. E. M. SYMMES

Soil fertilization for sugar beets (TYSON, MCCOOL) 15. Chemistry of starch. XXIV. New polyamyloses (PRINGSHEIM, *et al.*) 10. Lignin and cellulose. XIV. The hydrolysis of polysaccharides (FREUDENBERG, *et al.*) 10. Methylated tri- and tetrasaccharides from cellulose and starch (FREUDENBERG, FRIEDRICH) 10. A new spectral colorimeter (SPENGLER, LANDT) 1.

Purifying sugar-house and refinery juices. DARIO TEATINI. Fr. 693,437, April 5, 1930. See Belg. 367,847 (*C. A.* **25**, 838).

Plant for extracting sugar. ALOIS RAK. Ger. 515,007, May 6, 1927. See Brit. 286,125 (*C. A.* **23**, 302).

29—LEATHER AND GLUE

ALLEN ROGERS

Preservation of leather bookbindings. R. W. FREY AND F. P. VEITCH. U. S. Dept. Agr., *Leaflet* **69**, 8 pp.(1930).—Among the 7 dressings recommended, the following are examples: neat's-foot oil (pure, 20° cold test) 25 parts, anhyd. lanolin 17.5, pure Japan wax 10, powd. Na stearate 2.5 and distd. water 45. Another prepn. consists of pure petrolatum (petroleum jelly). These prepns. are well rubbed into the leather by hand or with a brush. A cellulose nitrate lacquer for the preservation of old powdery leather bindings consists of: cellulose nitrate (one-half sec., for lacquers, ready mixed with 30% by wt. of EtOH) 1 part, ethylene glycol or monoethyl ether 2, Et acetate 3, *n*-butyl alc. 1, toluene 5, xylene 2 and U. S. P. castor oil 0.5 part. The first 4 ingredients are put in a glass, tightly closed and allowed to stand with occasional shaking until a clear thick sirup is obtained. The last 3 ingredients, mixed together, are then added in a thin stream with const. stirring until a uniform mixt. results. The lacquer is best applied with a soft brush. C. R. FELLERS

Study of the action of yeast extracts on the constituents of hides. F. VAN WELDEN. *Bull. assoc. élèves inst. sup. fermentations Gand* **32**, 27–32, 39–41(1931).—The results of the expts. indicate that yeast exts. of p_H about 8, at 40° and at suitable concn., can be used for bating; by adding buffers such as phosphates and NH_4 salts the p_H of the hides is reduced. Active Cl (in the form of chlorohydrin) at a p_H of 9.3 is an excellent depilatory agent, which does not injure the texture of the hair. A. P.-C.

Use of calcium hydroxide prepared from marble in the leather industry. J. OETTINGER. *Chem.-Ztg.* **54**, 586(1930).—The product obtained by slaking marble lime sufficiently to yield a dry powder contains 96% $Ca(OH)_2$. By its use in liming, a large excess is unnecessary, stains and lime burns are avoided and the lime pits do not require to be emptied so frequently. This lime does not require to be slaked. It can be used for making lime paints or in liming glue pieces. B. C. A.

Composition of Burma cutch. ANON. *Bull. Imp. Inst.* **28**, 432–4(1930).—Analysis of: (1) 6 samples of com. Burma cutch, (2) 1 sample of Borneo cutch, (3) 1 sample of mangrove cutch and (4) 3 samples of "Krystal" cutch, gave the following results: water 13.0–15.9, 19.9, 20.0, 12.5–12.9; insol. matter 2.7–9.3, 3.8, 1.5, 3.6–4.2; extractive matter (nontannins) 17.5–26.3, 21.2, 21.0, 24.4–26.5; tannins (hide powder batch C_2) 54.7–60.4, 55.1, 57.5, 57.3–59.1; tannins (by cinchonine sulfate method) 45.4–48.0, 53.4, 57.4, 40.6–44.1; ash 1.9–4.2, 6.3, 5.5, 1.4–1.6; catechol 6.4–11.0, 0, 0, 14.2–17.2%. A. PAPINEAU-COUTURE

Complementary studies on mangrove barks from Madagascar. II. "Honkolahy" and its barks. F. HEIM DE BALSAC, A. JAMET AND H. HEIM DE BALSAC. *Bull. agence gén. colonies* **23**, 1176–94(1930); cf. *C. A.* **22**, 1055; **24**, 4652.—The botanical characteristics and the biology of Honkolahy (*Rizophora mucronata* Lam.) are described in detail. A sample of bark, about 1 mm. thick, from Sambirano, Madagascar, contained 30.3% tannin, as compared with 34.96% for older bark (5 mm. thick) from Ampasi-

marinu-Akbatorekitra (Majunga). Tanning tests carried out on demineralized calfskin were quite satisfactory, showing that the bark approaches quebracho for tanning purposes, except that it gives somewhat too bright a reddish brown tinge to the leather. The bark would be suitable for the local production of dry exts., or for exportation for the production of liquid exts. A. PAPINEAU-COUTURE

Tanning materials of New Zealand. P. WHITE. *Bull. Imp. Inst.* **28**, 450–3 (1930).– Tanekaha (*Phyllocladus trichomanoides*) bark was found to contain 17% tannins and 9.2% nontannins, as compared with 23–8% tannins reported by an earlier investigator, probably because the later sample was from younger trees. Kamahi (*Weinmannia racemosa*) bark from a 12-in. diam. tree, an 18-in. tree and a very old tree contained: tannins 14.5, 22.2, 30.0; nontannins 5.9, 5.9, 6.4%, resp. Tutu (*Coriaria ruscifolia*) has a very thin bark, which would not pay for stripping; the combined wood and bark of a 1-year old shrub and of a 10-year old shrub had: tannins 2.7, 3.1; nontannins 10.3, 8.3%. Samples of com. black wattle (*Acacia mollissima*) bark grown in New Zealand contained 37–40% tannins and 9–11% nontannins; silver wattle (*A. dealbata*) bark contained 12.2–22.1% tannins and 9.5–12.1% nontannins; bark of a hybrid between black and silver wattle, which is immune to frosts and fungus disease, contained 25.8% tannins and 11.3% nontannins. Bark from 7-, 16- and 26-year old trees of *A. decurrens* var. *normalis* contained: tannin 18.9, 28.4, 36.6; nontannins 13.1, 11.2, 10.8%, resp. Other species of acacia had the following tannin and nontannin contents: *A. melanoxylon* (Rotorua) 15.2, 9.9; *A. longifolia* 12.4, 8.0; *A. prominens* 23.4, 12.3, *A. Baileyana* 17.7, 10.1, *A. lunata* 22.4, 12.7, *A. decurrens* var. *Leichardii* (New Plymouth) 33.3, 7.3, *A. penninervis* (New Plymouth) 28.2, 7.3% Most of these samples were taken from comparatively old trees, *viz.*, 20 yrs. Two samples of fungus galls (1-year old and much older) contained: tannin 13.4, 28.3; nontannins 22.8, 9.2%, resp. The water ext. of the older galls was of a deep red color and had a p_H of 5.8; on adjusting the latter to 4.8 the color was reduced nearly to that of a normal black wattle soln. of similar strength. All results are given on a 10% water basis. A. PAPINEAU-COUTURE

Skin glues and bone glues. H. MAIER-BODE. *Kunstdünger- u. Leim-Ind.* **26**, 327–9, 339–41, 351–4(1929).– It is confirmed that the viscosity of fresh glue liquor is smaller than that of a sol of equal concn. prepd. from the solid material; it is considered that, on drying, reaggregation of the glutin takes place. Skin glues and bone glues are conveniently tested by detg. the viscosity of a 17.75 or 20% soln. at 30° and 40°. A modification of Ostwald and Köhler's (*C. A.* **22**, 2865) test differentiates skin glue from bone glue. B. C. A

The condensation of catechol tannin (BERGMANN, POJARLIEFF) **10.**

Bleaching leather, skins, furs, etc. ANDRÉ CORNILLOT. Fr. 692,981, July 6, 1929. Leather, skins, furs, etc., are bleached in a bath contg. peracetic acid prepd., *e. g.*, by the action of H_2O_2 on Ac_2O. Salts such as phosphates, borates, alkali salts of org. acids or a base such as NH_3 are preferably present.

Greasing leather. HERMANN BOLLMANN and BRUNO REWALD. Ger. 514,399, July 17, 1927. A mixt. of lecithin and fatty oil is used, *e. g.*, equal quantities of lecithin and train oil.

Leather substitutes. SOC. FLEURY ET LAVANANT. Fr. 692,988, July 8, 1929. A leather substitute is made by treating unsized paper with strong H_2SO_4 charged with HCl, applying the product to cloth and neutralizing, washing and drying.

Demineralization of bones. GÉLATINES HASSELT ET VILVORDE, SOC. ANON. Belg. 371,121, July 31, 1930. The bones are treated with aq. H_3PO_4. The acid liquor is regenerated by adding it to a bath contg. a sufficient quantity of H_2SO_4 so that there will be no excess of liquor until the whole of the $CaSO_4$ has been pptd.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The rubber industry in the United States. L. P. MAX. *Rev. gén. caoutchouc* **7**, No. 65, 3–6; No. 66, 3–8(1930). C. C. DAVIS

A few facts on the study of rubber-bearing plants of the Russian Soviet Republic. SERGIUS IVANOV, T. S. CHELZOVA, S. B. RESNIKOVA, E. I. TROFIMOVA, E. M. DUHNE AND V. I. SVESHNIKOVA. *Kautschuk* **6**, 237–9, 256–8(1930).—The results of an in-

vestigation of over 150 plants are described, with analytical data tabulated in detail. The most promising raw material was the rubber of the *Chondrilla*, the "naphivi" of which with suitable improved methods yield considerable rubber. C. C. DAVIS

The significance of the primary valence chain theory in explaining the structure of rubber. EUGENIO LINDMAYER. *Kautschuk* **6**, 249–52(1930); cf. *C. A.* **24**, 750.—A review and discussion. C. C. DAVIS

The plasticizing of rubber. F. JACOBS. *Rev. gén. caoutchouc* **7**, No. 67, 19–26 (1930); cf. *C. A.* **25**, 1117.—Various wood resins, tars, pine tars and oils are described and discussed, with quant. data (already published). C. C. DAVIS

An aging test with kerbosch rubber. R. RIEBL. *Arch. Rubbercultuur* **14**, 411–20 (1930)(In briefer form in English 421 4).—Kerbosch rubber and latex-sprayed rubber were kept at av. temps of 27° and 18° (at places with different climates) to ascertain the influence of different climatic conditions on the aging of both types of whole latex rubber. The Kerbosch rubber deteriorated badly at sea level, but nowhere nearly so rapidly at 5000 ft. elevation (cf. de Vries, *C. A.* **18**, 2265). The latex-sprayed rubber aged much better than the Kerbosch rubber, and furthermore the aging of the former was not so disproportionately bad at sea level. The results in general show the important influence of climate on the aging of rubber of the Kerbosch type. C. C. D.

Manufactured rubber, its keeping qualities and reconditioning. P. BRUÈRE. *Arch. méd. pharm. militaires* **91**, 571(1929); *J. pharm. Alsace Lorraine* **57**, 219–28 (1930), cf *C. A.* **24**, 3397. S. WALDBOTT

The Kelly abrasion machine. A. F. HARDMAN, W. L. MACKINNON AND S. M JONES *Rubber Age* (N. Y.) **28**, 463 5(1931).—The new machine, which is described and illustrated, is designed to simulate the road wear of tires, with special attention to 3 factors: (1) increasing and diminishing pressure of contact of the rubber with the abrasive material, (2) application of only part of the surface to the abrasive material and (3) a side slip as the rubber leaves the abrasive surface. With this method, actual road wear can be foretold reliably. C C. DAVIS

Modern methods of cycle tire vulcanization. A. FRÖLICH. *Gummi-Ztg.* **45**, 543 (1930), *India Rubber J* **81**, 154 7(1931). - An illustrated description. C. C. DAVIS

The influence of S dusting on rubber production (AMENT) **15**. Rubberized cloth (Fr pat. 693,890) **25**. Rubberized conveyor belts (Brit. pat. 335,475) **1**. SeS_2 [for vulcanization] (Fr. pat. 692,758) **18**.

VAN HARPEN, N. H.: **The Electrometric Determination of the Hydrogen-Ion Concentration in the Latex of Hevea Brasiliensis and Its Applicability to Technical Problems.** Medan (Java). Varekamp en Co. 459 pp. Reviewed in *Chimie & industrie* **25**, 266(1931).

Rubber articles from latex. SOC. ITALIANA PIRELLI. Brit. 335,621, June 27, 1929. In a process generally similar to that described in Brit. 292,964 (*C. A.* **23**, 1527), in which latex with a small proportion of certain added coagulants is subjected to local heating to produce coagulation, normal latex is heated to a moderate temp. (suitably 40–60°) and cooled prior to the introduction of the coagulants. Various details of procedure are given.

Rubber. I. G. FARBENIND. A.-G. (Curt Meisenburg, inventor). Ger. 511,540, Nov. 13, 1925. Liquid polymerized substances are removed from rubber-like condensation products (*e. g.*, from butadiene) by treatment with powd. absorbents such as active C, active SiO_2, etc.

Rubber, etc., dispersions. THE DUNLOP RUBBER CO., LTD., and THE ANODE RUBBER CO., LTD. Fr. 692,532, Mar. 21, 1930. In the manuf. of articles from org. dispersions of rubber, gutta-percha, balata or like vegetable resins, the surface of the molds or formers is covered with a film of dehydrating and coagulating liquid before immersion in the dispersions. Thus, the molds may be inserted in a concd. soln. of $AcONH_4$, NaCl or NH_4Cl, to which an acid or a mixt. of acids may be added.

Rubber dispersions. NAUGATUCK CHEMICAL CO. Brit. 335,597, June 20, 1929. Rubber dispersions are prepd. as water-in-oil emulsions by emulsifying water in oil with suitable emulsifying agents and adding rubber before, after or during the emulsification, with subsequent mixing to effect dispersion. The products can be used in substantially the same manner as rubber-solvent doughs are used in making spread or coated fabrics. Numerous details and examples of procedure are given. Cf. *C. A.* **24**, 751.

Preservation of rubber. WALDO L. SEMON (to The B. F. Goodrich Co.). Can.

308,541, Feb. 10, 1931. Rubber is preserved by treating with the resinous condensation product of p-$C_6H_4(NHPh)_2$ with CH_2O. Cf. *C. A.* **24**, 2329.

Rubber treatment to increase resistance to deterioration from age. WM. S. CALCOTT and WM. A. DOUGLASS (to E. I. du Pont de Nemours & Co.). U. S. 1,790,794, Feb. 3. Rubber compns. are treated, before vulcanization, with (as anti-aging addns.) 3-hydroxy-3-methoxybenzylaniline (suitably 1-5%) or various other substances which may be obtained by the reaction of an aromatic primary amine with formaldehyde and a phenolic compd., as described in German patent 109,498. The resulting products are mixts. contg., in each instance as the major constituent, a hydroxybenzylaryl amine having the general formula R—NH—CH_2—R′—OH, in which R represents an aryl group which may or may not contain alkyl substituents and R′ represents an aryl group which may or may not contain alkyl and alkoxy substituents. Various examples and details of procedure are given.

Antioxidant for rubber. PAUL C. JONES (to The B. F. Goodrich Co.). Can. 308,542, Feb. 10, 1931. Rubber is preserved by incorporating with it tetraphenylhydrazine before vulcanization.

Rubber stock treatment. HENRY L. MORAN. U. S. 1,790,875, Feb. 3. Rubber stock is passed through a receptacle contg. water heated to about its b. p., to soften the rubber without cure or vulcanization. App. is described.

Apparatus for forming and calendering rubber or rubberized fabrics or strips. DUNLOP RUBBER CO., LTD., and H. WILLSHAW. Brit. 335,657, July 10, 1929. Mech. features and details of app. are described.

Sponge rubber. REGINALD J. NOAR. Ger. 515,340, May 26, 1928. See Brit. 284,938 (*C. A.* **22**, 4877).

Ornamenting rubber articles. LIVERPOOL RUBBER CO., LTD., and G. THORNE. Brit. 335,612, June 28, 1929. Articles produced directly on a former from aq. dispersions of rubber, gutta-percha, balata or the like, are ornamented by dipping them while still on the former into water on the surface of which are floated streams of suitable colored solns. such as rubber solns. contg. pigments such as CdS or vermillion.

Regenerating rubber. LOUIS BEAUDOIN. Fr. 692,982, July 6, 1929. Waste rubber of all kinds is regenerated by heating it rapidly to 250-280° until the mass becomes bright; this change corresponds to the max. devulcanization which it is possible to obtain. An app. is described

Substances resembling hard rubber. I. G. FARBENIND. A.-G. Fr. 692,606, Mar. 24, 1930. Substances resembling hard rubber are obtained by vulcanizing products obtained by the polymerization of erythrene. Examples are given.

Porous ebonite articles. MEYER WILDERMAN (to American Wilderman Porous Ebonite Co.). U. S. 1,791,437 Feb 3. In forming porous articles such as diaphragms, the surface portions are formed of initially uncured ebonite occupying such volume that adjacent particles are in contact but are not compacted into a nonporous solid mass, the coatings of the particles being united by vulcanization between themselves and with the enclosed ebonite particles.

Synthetic rubber. I. G. FARBENIND. A.-G. Fr. 691,662, Mar. 10, 1930. A product resembling rubber is obtained by polymerizing 1,3-butadiene, a small quantity of water being added during the reaction. The water added may be in the form of water of crystn. in salts, *e. g.*, $Na_2CO_3.10H_2O$ or $MgCl_2.6H_2O$. Cf. *C. A.* **24**, 6065

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 335,616, June 29, 1929. Mixed rubber-like masses are produced by partially polymerizing a diolefin as described in Brit. 307,308 (*C. A.* **23**, 5352), adding a different diolefin (such as 2,3-dimethylbutadiene if butadiene or isoprene is used as the initial material), and then further polymerizing. Various details and examples are given. Cf. *C. A.* **25**, 1120.

Synthetic rubber compositions for tires. I. G. FARBENIND. A.-G. Brit. 334,958, June 15, 1929. Butadiene polymers used for tire manuf. as described in Brit. 299,037 (*C. A.* **23**, 3376) are replaced by a mixt. of these polymers with a natural or artificial resin. Various details and examples are given.

Artificial rubber. I. G. FARBENIND. A.-G. (Helmuth Meis, Wilhelm Klein and Eduard Tschunker, inventors.) Ger. 515,143, July 21, 1927. Butadiene hydrocarbons, in aq. emulsion, are polymerized by addn. of a small quantity of a finely divided or colloidal heavy metal oxide which does not yield H_2O_2 when treated with acids. MnO_2 and PbO_2 are suitable oxides. Protective colloids may be included in the emulsions, and the oxide may be formed *in situ*. Examples are given.

Vulcanizing rubber. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 693,178, April 2, 1930. Rubber and like substances and vulcanizable oils are vulcanized in the presence of an *N,N*-dithio deriv. of a secondary amine such as *N,N*-dithiopiperidine.

CHEMICAL ABSTRACTS

Vol. 25. APRIL 20, 1931 No. 8

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

A device for determining work input to a laboratory ball mill. JOHN GROSS AND STUART R. ZIMMERLEY. Bur. Mines, *Rept. of Investigations* 3056, 3 pp.(1931). ALDEN H. EMERY

A satisfactory laboratory cement. V. T. JACKSON. *Chemist Analyst* 20, No. 2, 23 (1931).—Directions are given for making cements from asphalt, rosin, rubber and turpentine; such cements are used for *making gas-tight joints in apparatus.* W. T. H.

The shape of clamps. WILHELM VOLKMANN. *Chem. Fabrik* 1931, 62–3; cf. *C. A.* 23, 733.—The geometry of lab. clamps is discussed as a possible basis for standardization. J. H. MOORE

Modification of the Seitz 20-ml. filter. N. W. LARKUM. *Am. J. Pub. Health* 21, 193–4(1931); cf. *C. A.* 23, 3601.—Wider and thicker flanges make possible the application of much more pressure, which is necessary to assure an adequate seal in order to prevent air leakage with its consequent contamination of the filtrate. J. A. KENNEDY

Filters for the reproduction of sunlight and daylight and the determination of color temperature. RAYMOND DAVIS AND K. S. GIBSON. Bur. Standards, *Miscellaneous Pub.* No. 114, 165 pp.(1931). E. H.

Mechanical stirrer. IRWIN STONE. *Chemist Analyst* 20, No. 2, 18–9(1931).—Directions are given for making a stirrer; an old elec. motor or converted fan is used as power. W. T. H.

A generally applicable shaking apparatus. P. DICKENS. *Chem. Fabrik* 1931, 61–2; cf. *C. A.* 22, 3554; 23, 4905.—Two motor-driven shakers are described, one for use with ordinary glass app., the other for connected app. for carrying out reactions with air exclusion. J. H. MOORE

A flask, divided in the middle, for evaporating and drying in a vacuum, boiling with reflux, and extracting. ARNOLD LUBINSKI. *Chem. Fabrik* 1931, 78. J. H. MOORE

Improvised drying oven. GEO. W. CORRIE. *Chemist Analyst* 20, No. 2, 16 (1931).—For drying a no. of bulky objects at 50° it was found possible to make use of a small oven placed in the hood with a baffle plate in front of it. A cut of the arrangement is shown. W. T. H.

Water baths. LESTER MEYER. *Chemist Analyst* 20, No. 2, 16(1931).—An arrangement for keeping the level const. in the bath is shown. W. T. H.

Hot water as a means of attaining higher temperatures. BATTIGE. *Apparatebau* 42, 217–19(1930).—An air-heating system for use in drying rooms is described. Pipe bank "boiler" and heating coils. M. C. ROGERS

Method for preventing an exhaust tube from shutting off on a water-cooled condenser. RUSSELL P. EASTON. *Chemist Analyst* 20, No. 2, 21(1931).—By using a test-tube clamp on the upper outlet of a condenser mantle, collapse of the rubber tubing, which would impede the flow of the water, is prevented. W. T. H.

A practical viscometer. H. R. HAMMOND. *Chemist Analyst* 20, No. 2, 21–2 (1931).—An improvised viscometer is shown which can be made at low cost. W. T. H.

An adjustable picnometer float. FERDINAND AMBRUST. *Chemist Analyst* 20, No 2, 22–3(1931).—In detg. d. by the picnometer method it is necessary to support the app. in a const.-temp. bath so that it remains immersed to the proper depth. A floating support is shown which accomplishes this. W. T. H.

Paraffining reagent bottles for alkaline solutions. WALTER B. DYE. *Chemist Analyst* 20, No. 2, 18(1931).—Directions are given for lining a bottle with paraffin so that standard alkali soln. can be kept without deterioration as a result of action upon the glass. W. T. H.

A modified Victor Meyer apparatus for the determination of molecular weights EUGENE W. BLANK. *J. Chem. Education* 8, 546–7(1931).—An easily constructed app

stance and a vehicle or agglutinant, and is then passed through a die before the coating is baked. App. is described.

Photoelectric cell. S. RUBEN (to Arcturus Radio Tube Co.). Brit. 336,397, Jan. 11, 1929. An electrode surface of etched Cu_2O is prepd. by heating a Cu electrode in an oxidizing atm. at 1000° and immersing it in a soln. of NH_4Cl or $ZnCl_2$ to produce a rough cryst. surface. The electrode is embedded in beeswax and resin in a cell and exposed in an electrolyte such as NH_4Cl. Cf. *C. A.* **24**, 2336.

Photoelectric cell. AUGUST KAROLUS and FRITZ SCHRÖTER (to Ges. für Drahtlose Telegraphie m. b. H.). U. S. 1,791,928, Feb. 10. Ne or He may be used as a filling.

Photoelectric cell. Soc. DES USINES CHIMIQUES RHÔNE-POULENC. Brit. 336,574, July 12, 1929. Various details are described of a gas-filled cell which may have a cathode of a layer of K and an anode and auxiliary electrode in the form of straight parallel wires. The auxiliary electrode is near the anode and is maintained at a fixed potential much lower than that of the anode, so that it acts as a non-photoelec. cathode when the potential applied to the anode nearly reaches the luminous discharge potential. Cf. *C. A.* **25**, 238.

Electric discharge device. N.-V. PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 336,563, July 8, 1929. App. for rectifying a. c. comprises a gas-discharge tube in which are located, in sep. chambers, an incandescent cathode (preferably an oxide cathode) and one or more anodes (such as graphite). Vaporized Hg may be condensed in the anode chamber. Various details of construction and operation are described. Cf. *C. A.* **25**, 851.

Electric discharge tubes for emitting ultra-violet rays, etc. N.-V. PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 336,222, July 5, 1929. For preventing impairment of the transparency of the tube walls to the rays generated, when the discharge is carried wholly or partly by a substance such as Mg which is likely to cause obscuration of the tube, the part of the tube wall intended for the passage of rays is coated with a substance (suitably KCl or KF in the case of Mg) which either prevents deposition or renders the deposit formed transparent to the rays desired. CaF_2 may be used as a coating for the interior of a Hg vapor lamp. K fluoborate also is suitable for use with tubes contg. Mg. When the tube contains Na vapor, the wall may be coated with S or P. Various details are described.

Metallic-vapor luminous discharge tubes. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN (to General Elec. Co., Ltd.). Brit. 336,490, July 13, 1929. In a lamp with a filling comprising vapor of Na, K, Hg, Li, Cs or Zn, with a rare gas or a gas such as N to facilitate starting, condensation of vapor in the electrode chambers is prevented by encircling the part of the tube remote from the electrodes with laminated or ribbed metal rings to promote cooling. Oxide electrodes may be used, heated by a filament. Various details of construction are described.

Cathodes for electric discharge tubes. VEREINIGTE GLÜHLAMPEN- UND ELECTRIZITÄTS- A.-G. Austrian 120,121, June 15, 1930. Cathodes of elec. discharge tubes made wholly or partly of glass are oxidized *in situ* by electrolyzing the glass so as to liberate O within the tube. The glass is locally heated, and the low-pressure gas filling of the tube is rendered conductive by maintaining a discharge in the tube. The cathode for the electrolysis is electrically connected outside the tube to the heated part of the glass, and the anode or cathode of the tube serves as the electrolytic anode. By interchanging the electrolytic anode and cathode, alkali or alk. earth metals may also be introduced into the tube. Cf. *C. A.* **25**, 1125.

Catalytic hydrogenation apparatus. TECHNICAL RESEARCH WORKS, LTD., and E. J. LUSH. Brit. 336,569, July 11, 1929. In app. having a Ni catalyst in the form of wire, turnings, or the like, packed in cages, the catalytic elements are constructed so that their thickness does not exceed 6 in., so that anodic oxidation may be thoroughly effected; an internal and an external cathode are used during the anodic oxidation process. Various details of construction and treatment are described.

Filler material for absorption towers. C. H. BUTCHER. Brit. 335,889, June 28, 1929. Hollow cylinders are used which after manuf. have had their sharp rough edges removed as by grinding; or tubes are used which are die-pressed so that they are free from sharp edges.

"Molecular pump." E. R. GROTE. Brit. 336,001, July 9, 1929.

Mechanical-stage construction for microscopes. C. BECK and C. J. BECK. Brit. 336,064, Sept. 4, 1929.

Fine-focusing construction for microscopes. C. BECK and C. J. BECK. Brit. 336,063, Sept. 4, 1929.

Air-treatment, humidifying and dehumidifying apparatus. THOMAS CHESTER. U. S. 1,791,751, Feb. 10. Structural features.

Apparatus (with a perforated inclined plate) for pneumatic separation of solids of different densities. R. H. KIRKUP. Brit. 336,055, Aug. 29, 1929. Structural features.

Continuous process for sterilizing milk or other liquids under pressure. N. J. NIELSEN. Brit. 337,027, June 27, 1929. Various details of app. and procedure are described.

Vacuum tank and heated tube system for condensing milk or other liquid products. N. J. NIELSEN. Brit. 335,964, June 5, 1929. Structural features and details of operation are described.

Apparatus for pasteurizing milk or other liquids by the "Holding Process." RICHARD SELIGMAN (to Aluminium Plant & Vessel Co., Ltd.). U. S. 1,792,328, Feb. 10. Structural features.

Apparatus for pasteurizing liquids in closed vessels. WILLY RÜPRICH. Ger. 513,522, Nov. 11, 1927. Details are given.

Apparatus for producing a foam-like mass from slag suitable for casting porous articles. NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI. Brit. 335,875, Feb. 27, 1929. Structural features of an app. with a horizontal or inclined container with stirrers, etc.

Apparatus and electrical system for magnetic tests of physical characteristics of iron or steel rods, etc. C. KINSLEY. Brit. 336,987, June 19, 1929.

Apparatus for continuous reactions between liquids under pressure. IMPERIAL CHEMICAL INDUSTRIES, LTD., and K. H. SAUNDERS. Brit. 336,136, Nov. 14, 1929. The app. for carrying out continuous reactions between liquids under pressure described in Brit 329,260 (*C. A.* 24, 5188) is constructed of corrosion-resisting material in the parts liable to be attacked by the reagents; *e. g.*, in an app. for the manuf. of *p*-nitroaniline from *p*-chloronitrobenzene and aq. NH_3 the outer tube may be protected by a mantle of "stainless steel," and the central tube may be formed of the same material. Various details of construction and operation of the app. are described.

Clarifying plant for liquids, particularly for coal and ore industries. PRÉPARATION INDUSTRIELLE DES COMBUSTIBLES. Ger. 516,454, Feb. 26, 1928.

Apparatus for determining specific gravity of solids or liquids. W. & T. AVERY, LTD., and W. A. BENTON. Brit. 336,043, Aug. 14, 1929. Numerous structural details are described.

Sterilizing apparatus for liquids, with heated filter. CARPULE G. M. B. H. and OSWALD PONTIUS. Ger. 516,007, Aug. 19, 1927.

Steam sterilizer. F. & M. LAUTENSCHLÄGER G. M. B. H. Ger. 516,008, May 23, 1928.

Mixing and emulsifying apparatus. VICTOR A. COLLINS. Ger. 516,443, Oct. 3, 1929. See Brit. 323,534 (*C. A.* 24, 2920).

Apparatus for extracting gases from liquids such as oils. SOCIETÀ ITALIANA PIRELLI. Fr. 693,985, April 15, 1930.

Apparatus for separating gaseous mixtures by liquefaction and rectification. SOCIÉTÉ L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS GEORGES CLAUDE). Fr. 694,035, Apr. 16, 1930.

Apparatus for washing gases with atomized liquids. G. RAW. Brit. 336,221, July 4, 1929. Various details of construction and operation are described of apparatus suitable for removing dust from air or other gases.

Air liquefaction system. M. HAZARD-FLAMAND. Brit. 336,798, Oct. 18, 1928. Various details of app. and procedure are described.

Apparatus for storing liquefied gases. CHRISTIAN W. P. HEYLANDT. Fr. 694,010, April 16, 1930.

Gas washers. PNEUMATIC CONVEYANCE U. EXTRACTION (1929), LTD. Ger. 513,527, Nov. 15, 1928. Addn. to 508,571 (*C. A.* 25, 622). Further details of a partitioned air, etc., purifier are given.

Apparatus for drying gases with sulfuric acid. RENÉ HAYOT. Fr. 694,038, April 16, 1930.

Wet and dry bulb apparatus for determining humidity of gases. CAMBRIDGE INSTRUMENT CO., LTD., J. L. ORCHARD and H. T. GLOVER. Brit. 336,855, Dec. 2, 1929. Various details are described of app. employing elec. resistance thermometers.

Apparatus for effecting catalytic reactions between gases at raised temperature and pressure. MARIA CASALE-SACCHI. Austrian 120,393, July 15, 1930.

Apparatus for ammonia synthesis and like catalytic gas reactions. HANS HARTER. Ger. 516,249, Aug. 11, 1926. See Brit. 275,983 (*C. A.* 22, 2444).

Drying apparatus (spraying or atomizing type). PAUL KLAHR. Ger. 517,177, April 3, 1927.

Drying apparatus with conveyors and several compartments separately controlled as to drying conditions. B. J. OWEN and R. O. DAVIES. Brit. 336,009, July 10, 1929. Various structural features and details of supply of heated drying gas, etc., are described.

Apparatus for drying materials successively on superposed trays. L. N. LLOYD and PHILLIPS ENGINEERING CO., LTD. Brit. 336,602, May 9, 1929. Structural features.

Tunnel drier and associated rotary air filter. TOMLINSONS (ROCHDALE), LTD., and J. N. TOMLINSON. Brit. 336,049, Aug. 22, 1929.

Removing oil and fat from the hot chambers of drying apparatus. LOTHAR WOLF and KARL KUNZE. Ger. 514,074, Aug. 29, 1929. Addn. to 478,637 (*C. A.* **23**, 4803).

Evaporating apparatus. SOC. DES CONDENSEURS DELAS. Ger. 516,365, May 22, 1927. Means is described for preventing the carrying away of froth by the vapors.

Apparatus for evaporating and cooling solutions. PAUL H. MÜLLER. Ger. 513,789, Nov. 21, 1924.

Means for removing salts from evaporators operated at reduced pressure. PAUL H. MÜLLER. Ger. 516,381, June 3, 1927.

Apparatus for evaporating liquids or crystallizing salt solutions. E. M. S. INDUSTRIAL PROCESSES, LTD., RICHARD A. STOKES and EDWIN G. L. ROBERTS. Fr. 694,553, Apr. 25, 1930.

Apparatus for developing crystals. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,014, Apr. 16, 1930. The vessel consists of an annular partition and means for circulating the liquor from the top downward in the central part and from the bottom upward on the sides.

Surface condenser suitable for use with steam. PAUL A. BANCEL (to Ingersoll-Rand Co.). U. S. 1,792,060, Feb. 10.

Apparatus for cleaning steam. COCHRANE CORP. Ger. 516,158, Jan. 18, 1929.

Apparatus for drying sludge for fertilizer or other materials by the action of heated circulating drying medium such as air or combustion products. JOHN B. BERRIGAN and JOHN J. BERRIGAN (to The Press and Drier Co.). U. S. 1,792,064, Feb. 10. Structural features.

Apparatus for eliminating carbon monoxide from motor-vehicle exhaust gases. HAROLD E. STORY. U. S. 1,791,912, Feb. 10. Various structural details are described of a device adapted for elec. heating of the gas in the presence of water vapor.

Wet classifier for pulverulent materials. LEONARD ANDREWS. Ger. 516,146, July 30, 1927. See Brit. 280,121 (*C. A.* **22**, 3005).

Heat-resisting cementation pot. FRIED. KRUPP A.-G. Fr. 694,665, April 29, 1930.

Device for indicating the presence of coal gas, etc., in the air. RICHARD LEISER. Austrian 120,184, Feb. 15, 1929.

Horizontal chamber furnace. STETTINER CHAMOTTE-FABRIK A.-G. VORMALS DIDIER. Ger. 513,594, Mar. 1, 1928. Details of closure are given.

Door-lifting apparatus for chamber furnaces. EBERHARD GRASSHOFF. Ger. 513,571, April 1, 1927. Details are given.

Fusion furnaces. ITALSICE (SOCIETÀ ANONIMA). Fr. 694,186, April 18, 1930. Construction of burner for using powd. fuel is described.

Inclined grate furnace. L. and C. STEINMÜLLER. Ger. 513,476, May 13, 1928. Addn. to 511,566 (*C. A.* **25**, 1126). Details of charging the forward part of the furnace.

Counterflow furnace suitable for heating articles in boxes. VEIT A. HAIN (to George J. Hagan Co.). U. S. 1,792,423, Feb. 10.

Burner for liquid fuel. TOM K. A. NORDENSSON. Fr. 694,349, April 23, 1930.

Boiler plant fired with pulverulent fuel. INTERNATIONAL COMBUSTION ENGINEERING CORP. Ger. 516,449, Oct. 27, 1925.

Pulverulent fuel burner. ROBERT S. WALKER. Ger. 516,257, Aug. 9, 1921.

Apparatus for distributing pulverulent fuel and air from a main to a number of branches. GEORGE R. ALDEN and CHARLES SKENTELBERY. Ger. 516,137, Oct. 7, 1928. Corresponds to Brit. 312,474.

Rotary-drum grate for finely granular fuels. WERNER SCHLEGEL. Ger. 516,483, Feb. 12, 1928.

Heat exchanger. SEMJON W. STAKIN. Ger. 513,844, Mar. 25, 1928. A heat exchanger for pre-heating the fuel gas consists of a mass of tubes of eliptical cross section.

Tubular heat-exchange apparatus. J. HOWDEN & Co., LTD., and J. H. HUMB. Brit. 336,755, Sept. 21, 1929. Structural features of an app. with metal pieces having

concave surfaces placed between rows of tubes to direct heating gases or the like in sinuous paths between the tubes.

Tubular heat-exchange apparatus. C. A. HUBERT. Brit. 337,236, Nov. 22, 1929. Structural features.

Method of heating furnaces by the waste heat of spent gases. C. OTTO & Co. G. M. B. H. Ger. 513,595, April 27, 1930.

Apparatus for removing ash without admitting air to the furnace. JULIUS JOSEF KELBER. Ger. 513,792, July 17, 1928.

Gas burner. GASTON B. KILLAM. U. S. 1,791,565, Feb. 10.

Gas burner. CLARENCE H. MORROW (to Hotstream Heater Co.). U. S. 1,791,509, Feb. 10.

Gas burner for heating boilers, furnaces, etc. J. E. WEYMAN. Brit. 336,722, Aug. 23, 1929.

Safety valve for gas burners. CLARENCE H. MORROW (to Hotstream Heater Co.). U. S. 1,791,530, Feb. 10. Structural details are described of a valve which cuts off gas supply to a main burner when a pilot light is extinguished.

Bunsen-burner attachment for producing radial horizontal flames. LOUIS TARTAZ. U. S. 1,791,913, Feb. 10. Structural features.

Retort door for resisting pressure. NICHOLS PRODUCTS CORP. Brit. 335,946, July 3, 1929.

Rotary kiln. HURON INDUSTRIES, INC., and B. E. GREEN. Brit. 336,729, Aug. 28, 1929. A sealing ring between a rotary kiln and its fixed ends is mounted so that its wt. tends to maintain a tight joint.

Tunnel kiln construction and heating system. V. LASTOVICKA. Brit. 336,171, Dec. 23, 1929. Various structural details are described.

Electric water heater. L. F. THOMPSON. Brit. 336,011, July 11, 1929. Structural features.

Acetylene generator. AUTOGENWERK SIRIUS G. M. B. H., THEODOR GEIS and AUGUST H. GIES. Ger. 513,612, May 16, 1929. Details of app. for generating C_2H_2 from water and CaC_2 dust are given.

Acetylene generator and lamp. WM. F. HUNT and HERMANN C. STELLING (to Union Carbide Sales Co.). U. S. 1,791,595, Feb. 10.

Thermostat. N.-V. NEDERLANDSCHE TECHNISCHE HANDEL MAATSCHAPPIJ "GIRO." Ger. 513,550, Sept 22, 1929. The device is applicable to hot water systems, the expansion or contraction of a rod opening or closing a rubber, etc., tube.

Thermostatic electric switch. R. MACLAREN. Brit. 337,093, Aug. 10, 1929.

Thermostatic electric switch. FELTEN & GUILLEAUME CARLSWERK A.-G. Brit. 337,162, May 6, 1929.

Thermostatic device for electrically operated fire alarms. JAMES R. LONGWORTH and HERBERT HIRST (Longworth to Hirst). U. S. 1,791,598, Feb. 10. Structural features.

Thermostatic and electrical control system suitable for piezoelectric crystal control systems. ALFRED CROSSLEY (to Federal Telegraph Co.). U. S. 1,791,804, Feb. 10. Structural and elec. features.

Thermostatic cut-out device for electric circuits. ADONIRAM J. GREEN (to General Elec. Co.). U. S. 1,792,299, Feb. 10. Structural features.

Thermostatic control for heating systems. JOHN M. LARSON (to National Regulator Co.). U. S. 1,792,101, Feb. 10. Structural features of app. employing a plurality of thermostats.

Thermostat construction suitable for control of fluid heating media. R. CARLSTEDT. Brit. 336,481, Nov. 25, 1929.

Thermostatically controlled reducing valve construction suitable for steam-heating systems. CLAYTON A. DUNHAM (to C. A. Dunham Co.). U. S. 1,792,213, Feb. 10.

Thermostatically controlled combined hot-water supply and heating system. HOPE'S HEATING & LIGHTING, LTD., and J. H. HARPIN. Brit. 336,125, Oct. 31, 1929. Structural and elec. control features.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Life and work of the late Professor A. C. Baer. R. B. BECKER. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention*, 158–62(1930).—Baer's investigations on ice cream are discussed in particular. K. D. JACOB

Two pioneers in agricultural chemistry of particular interest to the Association of Official Agricultural Chemistry. E. M. BAILEY. *J. Assoc. Official Agr. Chem.* **14**, 18–28(1931).—An address on the careers of John Pitkin Norton and Samuel W. Johnson. A. PAPINEAU-COUTURE

Evgenii Vladislavovich Biron (E. W. Byron). B. N. MENSHUTKIN. *J. Russ. Phys.-Chem. Soc.* **62**, 1749–76(1930).—A biography with portrait. E. J. C.

Rhodesian manganese mines of 7000 years ago. RAYMOND DENT. *Can. Mining J.* **52**, 150–1(1931).—The mines in the district east of Broken Hill, the primitive uses of minerals, the discovery of these mines and the uses of Mn in early civilizations are discussed. W. H. BOYNTON

The photoelectric measurement of luster. L. BLIN DESBLEDS. *Dyer, Calico Printer* **64**, 515–7, 583–5(1930); cf. *C. A.* **24**, 958. RUBY K. WORNER

Correlation of sieving analyses. H. HEYWOOD. *J. Inst. Fuel* **3**, 428–32(1930).—The variable factors entering into a sieving analysis are: personal factor, nature of powder, time, weight of powder, variation in sieve aperture. These are discussed. D. A. REYNOLDS

Hydrographic sections and calculated currents in the Gulf of Alaska. GEORGE F. MCEWEN, THOMAS G. THOMPSON AND RICHARD VAN CLEVE. *Rept. of the Intern. Fisheries Commission* No. **4**, 5–36(1930).—[Printed by Wrigley Printing Co., Vancouver, B. C., Can.]. The water was classified into 3 arbitrary types, *i. e.*, coastal water with a chlorinity less than 18 per mille and a value $\sigma_{s,t,o}$ less than 25.50, intermediate water underlying the coastal waters and having a chlorinity between 18 per mille and 18.50 per mille and a value of $\sigma_{s,t,o}$ between 25.50 and 26.40, and ocean water with a chlorinity greater than 18.50 per mille and a value of $\sigma_{s,t,o}$ greater than 26.40. $\sigma_{s,t,o} = (\text{d.} - 1)10^3$, where the d. is computed from the temp. and chlorinity but is not corrected for the pressure, p. In all 3 sections a cold surface layer lay over a deeper warmer stratum. The temp. and chlorinity data were treated hydrodynamically according to Bjerknes' theory (Publ. No. 88, Carnegie Inst. of Washington). C. R. FELLERS

Mixture formulas. K. K. JÄRVINEN. *Acta Chem. Fennica* **2**, 80–6(1929).—Formulas are given for prepg. certain solns. and similar formulas in the handbooks are discussed. All formulas are derived from the equation (1) $k_1p_1 + k_2p_2 = k_3p_3 = (k_1 + k_2)p_3$, where k means the wt. in kg. and p wts. percent. In the following l = vol. in l., v = vols. percent or g. in 100 cc. or normality, s = sp. gr., V = wt. *in vacuo* and A = wt. in air. By defining sp. gr. $s = k/l$ and substituting in formula (1): (2) $l_1s_1p_1 + l_2s_2p_2 = l_3s_3p_3 = \frac{l_1s_1 + l_2s_2}{\cdot}.p_3$. Since $p = vd/s$ and $k = ls$, where d = density of the dissolved substance, one gets from (1): (3) $l_1v_1 + l_2v_2 = l_3v_3 = \frac{l_1s_1 + l_2s_2}{\cdot}.v_3$ and for the contraction coeff. K: (3a) $K = \frac{l_3}{l_1 + l_2} = \frac{l_1s_1 + l_2s_2}{(l_1 + l_2)s_3}$. If one puts $p = vd/s$ in formula (1): (4) $\frac{k_1}{s_1}v_1 + \frac{k_2}{s_2}v_2 = \frac{k_3}{s_3}v_3 = \frac{(k_1 + k_2)}{\cdot}v_3$. These formulas are

theoretically exact only for vacuum, metric system and $st/4V$ at a certain temp., but are practically exact also in other circumstances. JOHN RYSELIN

The atomic number of elements. A study of the specific gravity of elements in liquid form. L. H. BORGSTRÖM. *Finska Kemistsamfundets Meddelanden* **36**, 76–81 (1927). J. RYSELIN

Was Mendelyeev's system known prior to 1869? G. ELSEN. *Chem. Weekblad* **27**, 378–9(1930).—A historical survey. The classification of the elements into 7 groups was proposed by Cooke in 1854. B. C. A.

Revision of the atomic weight of thallium. Analysis of thallous bromide. O. HÖNIGSCHMID AND H. STRIEBEL. *Z. anorg. allgem. Chem.* **194**, 293–8(1930).—The ratio TlBr/Ag was detd. by gravimetric titration. The mean of 6 detns. gave an at. wt. of 204.390 for Tl, with an av. individual deviation of 0.008, confirming the previous result 204.39 derived from analysis of TlCl (*C. A.* **18**, 1593). The wt. of AgBr formed by pptn. from TlBr came out high, which was ascribed to occlusion, and the resulting detns. of the ratio TlBr/AgBr were discarded. L. ONSAGER

An attempt to separate the isotopes of bromine. The atomic weight of bromine from the ratio of silver to silver bromide. P. HARTECK AND H. STRIEBEL. *Z. anorg. allgem. Chem.* **194**, 299–304(1930).—The mass differences of isotopes are expected to cause slight differences in the sp. heats and consequently in the vapor pressures at low temps.; on this basis a *reversible* sepn. is fundamentally possible. Fractional condensation of solid Br from the vapor in 3 stages (—18.5°, —25°, —36°) produced Br of at. wt. 79.916 ± .001 in the most volatile fraction from an initial material of pure ordinary Br, at. wt. 79.915 ± .001, both detd. from the ratio Ag/AgBr. The results confirm the value 79.916 (Ag = 107.880) found by Hönigschmid and Zintl (*C. A.* **18**, 771). L. ONSAGER

The interpretation of adsorption forces from atomic theory. F. LONDON AND M. POLANYI. *Naturwissenschaften* **18**, 1099–1100(1930).—Recently London (*C. A.* **24**, 5597) advanced a theory of mol. cohesion on the basis of the action of virtual oscillators as known in the theory of light refraction. This same theory is applicable to adsorption It is especially notable that this theory allows in first approximation simple superposition of the adsorption forces (cf. following abstract); this feature has not been included in other explanations of adsorption forces like the electrostatic theory or valence theory. The present theory is a good foundation for the potential theory of adsorption of Polanyi (*C. A.* **23**, 5079). The adsorption potential of a mol. at a distance d from the surface is $\phi = -(N\pi c/6)(1/d^3)$, N being the no. of surface atoms per cc., and c a const. The const. can be calcd. from the dispersion curve of adsorbent and adsorbate; it consists mainly of the product $\alpha\alpha'$ of the 2 mol. polarizations. Elec. dipole moment and higher moments are generally only of secondary influence. The adsorption forces become of the same nature as the van der Waals cohesion forces, expressed in his const. a. Further conclusions are: Adsorption forces are largely independent of temp., if the mols. are not too large or the dipoles too strong. The forces are independent of other substances present on the adsorbent. B. J. C. VAN DER HOEVEN

Properties and applications of molecular forces. F. LONDON. *Z. physik. Chem.*, Abt. B, **11**, 222–51(1930).—The intermol. forces can be calcd. approx. from purely optical data (*C. A.* **24**, 5597). In contradistinction to those observed electrostatically, forces so calcd. exhibit properties of a general cohesion, similar to the force of gravitation. The heat of sublimation, the heat of adsorption of adsorbed gases and the dissocn. energy are calcd. from the same data. Cf. *C. A.* **23**, 3399, 5094; **24**, 2651. C. L. W.

Curie points. L. F. BATES. *Proc. Phys. Soc. London*, **43**, Pt. I, 87–95(1931).—A description of the magnetic behavior of a ferromagnetic substance may require 3 temps., (1) the ferromagnetic crit. point, at which the rate of change of the square of the intrinsic magnetic moment per unit vol. with temp. is a max., (2) the ferromagnetic Curie point, at which the intrinsic magnetization may be considered zero and (3) the paramagnetic Curie point, given by θ in the Curie-Weiss law $\chi = C/(T - \theta)$. The significance of the ferromagnetic and paramagnetic Curie points is discussed in the light of the results of a no. of investigators on Fe, Ni, Co, the ferrocobalts, magnetite and manganese arsenide. The paramagnetic behavior of these substances can be accounted for by a slight extension of the idea that ferromagnetism is due to a magnetic particle consisting of a group of assocd. atoms. W. W. STIFLER

Magnetic susceptibility and chemical investigation. JAMES F. SPENCER. *J. Soc. Chem. Ind.* **50**, 37–41T(1931).—Possible applications of measurements of magnetic susceptibility in various types of chem. research are outlined. Since magnetic susceptibility in the rare earths is additive, it can be used in fractionation as an index of the

degree of sepn. of the constituents. For this purpose it is often more convenient and more sensitive than the "mean equiv." In the study of alloys, variation of susceptibility with compn. often reveals intermetallic compds. This application is illustrated by examples from the work of a no. of investigators on Pb-Sn, Bi-Sn, Pb-Ag, Pb-Au, and Al-Sn series of alloys. Evidence of O_4 mols. from susceptibility measurements is then discussed. Susceptibility detns. may be used to measure the velocities of chem. reactions and may also find application in studying assocn. and dissocn. in binary mixts. of org. liquids. Calcns. based on susceptibility measurements prove that Willgerodt's paramagnetic org. compd. cannot have the formula usually attributed to it. Formation of the compd. BiO is highly improbable. W. W. STIFLER

Effect of internal stresses on the magnetic susceptibility of metals. KOTARO HONDA AND YOSOMATSU SHIMIZU. *Nature* **126**, 990–1(1930).—The adaptability of Cu to cold working was measured by Weiss's electromagnetic method. The decrease in d. during cold working measures the internal stress. As the d. decreased from 8.921 to 8.87, the susceptibility changed linearly from $\chi = -0.083 \times 10^{-6}$ to $\chi = +0.063 \times 10^{-6}$, that is, the Cu changed from diamagnetic to paramagnetic. On heating slowly to 500° the original diamagnetism was restored between 230° and 330°, proving that cold working set up internal stress. During cold working of Ag the d. changed from 10.489 to 10.439 and the susceptibility from -0.200×10^{-6} to -0.140×10^{-6}. These results are in accord with H.'s theory of magnetism. W. W. STIFLER

Magnetic forces in a crystal of the type of rock salt. J. BOUMAN. *Arch. neerland. sci.* IIIA, 13, 1–28(1930).—A highly math. discussion in which it is shown that certain crystals similar in type to rock salt may be constructed in which the atoms have definite magnetic moments. The assumption that the moments of the 2 atoms are equal is not necessary, although when this assumption is made the formulas are less complicated than those developed without it. W. W. STIFLER

Change of the dielectric constant of nitrobenzene with temperature. J. MAZUR. *Nature* **126**, 993(1930); cf. *C. A.* **25**, 627.—The dielec. const. of carefully purified $PhNO_2$ was measured at a no. of temps. between +30° and −75° by a method based on the beat frequency between 2 high-frequency circuits. The temps. were measured to 0.005° and the method was sufficiently sensitive to show a change in the 5th decimal place of the dielec. const. The dielec. const. increases steadily from 35.4 at 30° to 38.18 at 9.6°, then drops abruptly to 11.82 at 7.713°, after which it diminishes gradually to 9.709 at −75°. W. W. STIFLER

The thermal resistivity of solid dielectrics. ANON. *J. Inst. Elec. Eng.* (London) **68**, 1313–55(1930).—The study is divided into four parts: (1) a study of the thermal resistivity of solid dielectrics when tested in sheet form, and of factors influencing the flow of heat through them; (2) a study of the thermal resistivity of solid dielectrics when applied to bars by the usual shop processes of wrapping; (3) a study of the thermal resistivity of sheet steel stampings transverse to the laminations and (4) a study of the thermal resistivity of air spaces. The appendix contains an estn. of the thermal conductivity of the insulation on a rectangular bar and a bibliography. The various forms of app. employed, as well as curves and results, are shown. W. H. BOYNTON

Specific heat of gases. H. LOURIÉ. *Chaleur et ind.* **11**, 423–35(1930); cf. *C. A.* **24**, 5555.—A discussion of methods for detg. the length of sound waves in gases. The The methods are classified as (1) dust methods, (2) methods of reënforcement of vibrations, (3) interference methods and (4) direct measurement. For the gases N_2, O_2, CO, air, CO_2 and H_2O at 0–2000° the following are tabulated: (*a*) velocity of sound in an unlimited gaseous atm., (*b*) C_p at 1 kg., (*c*) C_v at 1 kg., (*d*) av. C_p at 1 kg., (*e*) av. C_v at 1 kg., (*f*) C_p at 1 cu. m. (0/760), (*g*) C_v at 1 cu. m. (0/760), (*h*) the resp. av. values. Values of numerous experimenters for O_2, N_2, H_2, CO, CO_2, air are also tabulated. Curves are given for the mol. sp. heats of these gases. 82 references. S. L. B. ETHERTON

Calculation of gas equilibria from spectroscopic data. I. J. M. BIJVOET. *Chem. Weekblad* **28**, 26–37(1931).—A discussion of the calcn. of entropy consts. by statistical methods from spectral data. E. SCHOTTE

A measurement of molecular velocity and a test of the cosine law. P. CLAUSING. *Ann. Physik* [5], **7**, 569–78(1930).—Measurements of the time of passage $\bar{t}$ of A and Ne through a narrow cylindrical capillary at very low pressures, non-stationary flow being used, agreed within 1–3% with the formula: $\bar{t} = L^2/4ru$ (L = length, r = radius, $u = (8RT/\pi M)^{1/2}$ = mean mol. velocity). The derivation of this formula from kinetic theory assumes Maxwell's law for mol. velocities and the cosine law for the reflection (or reëvapn. after temporary adsorption) of mols. from the walls. The accurate con-

firmation of the given formula for $\bar{t}$ excludes material deviations from the cosine law, *e. g.*, an appreciable fraction of the mols. specularly reflected. L. ONSAGER

Reflection and period of adherence of metal atoms on oil surfaces. G. VESZI. *Z. physik. Chem.*, Abt. B, **11**, 211–21(1930).—Vapors of Cd, Zn, Tl, Pb and Bi were directed through a narrow opening against a moving (15 m. per sec.) olive oil surface and reflected back a distance of 0.2 cm. onto a wall cooled by liquid air. The distance on both sides of the opening in which the thickness of the deposited metal was uniform was used as a measure of the distribution curve. This method gave definite proof that Zn, Cd and Bi adhere to the reflecting surface. The period of adherence was 10^{-5} to 10^{-4} sec. Cf. Holst and Clausing (*C. A.* **20**, 1737). CURTIS L. WILSON

Vapor pressures of some hydrocarbons. ERNEST G. LINDER. *J. Phys. Chem.* **35**, 531–5(1931).—The vapor pressures at temps. in the neighborhood of 0° are given for toluene, tetrahydronaphthalene, *m*-xylene, *o*-xylene, *p*-xylene, dipentene, ethylbenzene, mesitylene, octane, durene, tetradecane, decane, butylbenzene, *sec.*-butylbenzene, *tert.*-butylbenzene, *p*-diethylbenzene, *m*-diethylbenzene, propylbenzene, isopropylbenzene, octylene, diisobutylene, 2,2,4-trimethylpentane, decane, hexamethylethane, *p*-menthane, *p*-cymene, styrene, 1-methylcyclohexene, methylcyclohexene, limonene, pinene, decahydronaphthalene, methylnaphthalene, cyclohexene, diphenylmethane, acenaphthene and *o*-diphenylbenzene. MALCOLM DOLE

Heat transfer in liquid ammonia. III. M. HIRSCH. *Z. ges. Kälte-Ind.* **38**, 5–8(1931). F. D. ROSSINI

Measurements with the aid of liquid helium. XI. The resistance of certain metals at low temperatures. W. MEISSNER AND B. VOIGT. *Ann. Physik* [5], **7**, 761–97(1930); cf. *C. A.* **25**, 243. —The resistances of metals of the first 2 periodic groups and of B, Al, In and Tl were measured from 273°K. down to the temp. of liquid He. The characteristic temps. for these metals were calcd., the Grüneisen formula being used. C. E. P. JEFFREYS

Determination of the coefficient of diffusion of metals in the solid state. SHINSUKE TANAKA AND CHUJIRO MATANO. *Proc. Phys.-Math. Soc. Japan* [3], **12**, 279–84(1930); cf. *C. A.* **25**, 1135.—The coeff. of diffusion was detd. at 500° for alternate layers of Au and Ag by measuring the change of elec. resistance with time. Fick's law was found valid. MALCOLM DOLE

The question of molecular or atomic solid solution of an intermetallic compound in a pure metal. G. WASSERMANN. *Z. Metallkunde* **22**, 158–60(1930).—Soln. of Mg in Al increases a_0 (the side of the unit face-centered cube of Al) from 4.0404 A. U. to 4.0535 A. U. in an alloy contg. 3 at. % Mg. Soln. of Zn decreases a_0 from 4.0404 to 4.0330 A. U. in an alloy contg. 10 at % Zn. When 1 at. % Mg and 2 at. % Zn($MgZn_2$) are added to Al, a_0 increases to 4.0420 A. U., which is only slightly lower than the change in a_0 calcd. additively from the effects of Mg and Zn taken separately. The vols. of 1 Mg atom plus 2 Zn atoms, and of 1 mol. of $MgZn_2$ are in the ratio of 1.08 to 0.98 on the basis of the vol. of 3 Al atoms (which they presumably replace in the solid soln.) = 1.00. Thus if $MgZn_2$ dissociates into atoms when dissolving in Al the Al lattice should expand, whereas if $MgZn_2$ dissolves as mols. the Al lattice should contract. The observed expansion of the Al lattice is taken an indicative of an at. solid soln. rather than a mol. ROBERT F. MEHL

The unipolarity of pressed lead sulfide. FR. TREY. *Naturwissenschaften* **18**, 1099(1930). —PbS crystals with detector qualities become inactive after pulverization and pressing; pptd. PbS after being pressed to a pastille is also inactive. However, after heating to 150° the prepns. assume rectifier properties (*C. A.* **20**, 1156). After repeated pressing these properties disappear again and reappear on heating. The resistance of the prepns. changes simultaneously with the rectification effect (Bridgman, *C. A.* **20**, 1542). Both properties depend on the structural qualities of the crystals. B. J. C. VAN DER HOEVEN

Röntgenographic investigation of the system cadmium–magnesium. U. DEHLINGER. *Z. anorg. allgem. Chem.* **194**, 223–38(1930).—In the system Cd–Mg there are 2 series of mixed crystals, α and β. Both are hexagonal. The α crystals exhibit the same axial ratio as pure Cd, namely $c/a = 1.89$, while β crystals, like pure Mg, exhibit the ratio $c/a = 1.62$. These ratios are independent of concn., and all lattices found belong to one of the types α and β. However, for crystals contg. 25–65 at. % of Mg, a transformation between the 2 may be effected by pressure (or mech. treatment), which favors β with approx. 2% smaller vol. Compds. with "hyperstructure" exist, the most important being $MgCd_3$ (α lattice) and $CdMg_3$ (β lattice); both were measured, the latter by the rotating-crystal method. A different type of hyperstructure was indicated by x-ray lines from alloys with about 50% Mg. L. ONSAGER

The ternary system potassium oxide, calcium oxide, silica. G. W. MOREY, F. C. KRACEK AND N. L. BOWEN. *J. Soc. Glass Tech.* **14**, 149–87T(1930); cf. *C. A.* **24**, 5448. —The phase relationships of these 3 rock-forming ingredients are described in detail. The quenching method developed so successfully by the Geophysics Lab. was used, great care being observed to insure homogeneity of the melts. More compds. are formed in the K_2O–CaO–SiO_2 system than in the Na_2O–CaO–SiO_2 system, and there is a greater tendency for these compds. to dissoc. on melting; the viscosity of the melts at the liquidus is greater over a large proportion of the diagram; and the crystn. and melting processes are more sluggish. The following new compds. were found and their equil. fields and properties detd.:

	Percent of K_2O	CaO	SiO_2	M. p. or Reaction $t°$	Crystal Habit
$K_2O.2CaO.9SiO_2$	12.61	15.01	72.38	1050 ± reaction	Prisms and plates
$4K_2O.CaO.10SiO_2$	36.46	5.43	58.12	946	Plates

H. F. K

ucture of cubic Carborundum. H. BRAEKKEN. *Z. Krist.* **75**, 572–3(1930).—Laue and rotation photographs on a small crystal of cubic SiC give results which agree with the powder photographs reported by Ott (*C. A.* **20**, 3106).

L. S. RAMSDELL

The crystal structure of iron silicide, FeSi. F. WEVER AND H. MÖLLER. *Z. Krist.* **75**, 362–5(1930).—A new detn. of the structure of FeSi (cf. *C. A.* **18**, 3033) gives $a = 4.467$ A. U. There are 4 mols. in the unit cube, and the Fe and Si atoms have the positions 4*f*, with $u_{Fe} = 0.1340$ and $u_{Si} = 0.8445$. The distance Fe — Fe is 2.74 A. U. and Si — Si is 2.76 A. U. Since each atom has a single atom of the opposite kind as its nearest neighbor, the structure can be considered as made up of FeSi mols.

L. S. RAMSDELL

Crystal structure of the compound Fe_2B. GUNNAR HÄGG. *Z. physik. Chem.*, Abt. B, **11**, 152–62(1930).—"A new structure is established for Fe_2B which, for spatial reasons, is more probable than the structure assumed by Wever and Müller (*C. A.* **25**, 20–1). It also offers a better explanation of the observed distribution of intensities" (on powder photograms). "The Fe atoms are located in the corners of tetrahedrons that form a highly uniform system. The B atoms are located in the largest intervals between these tetrahedrons." "Each B atom is surrounded, at equal distances of 2.176 A. U. by 8 Fe atoms. This structure indicates that the B atom has a radius of 0.97 A. U."

G. TOENNIES

The cubic high-temperature structure of some perchlorates. H. BRAEKKEN AND L. HARANG. *Z. Krist.* **75**, 538–49(1930).—The structure detns. by Herrmann and Ilge (*C. A.* **25**, 1420) for the alkali perchlorates are largely verified, although there are some minor disagreements. Parameters and interatomic distances are given.

L. S. RAMSDELL

The crystal structure of calcium chromate. J. H. CLOUSE. *Z. Krist.* **76**, 285–6 (1930)(in English).—X-ray data show definitely that $CaCrO_4$ is not orthorhombic and isomorphous with $CaSO_4$, but rather is tetragonal, and isomorphous with zircon, $ZrSiO_4$. The unit cell contains 4 mols., $a = 7.10$ A. U., $c = 6.19$ A. U.; the calcd. d. is 3.27; the space group is D_{4h}^{19}.

L. S. RAMSDELL

Large transparent cubic crystals of sodium chloride. TAKEMARO YAMAMOTO.

Bull. Inst. Phys. Chem. Research (Tokyo) **10**, 52–60(1931)(Abstracts 4–5 (in Esperanto) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, Nos. 283–5).—Various cations have a catalytic effect on the crystn. by slow evapn. of a satd. NaCl soln. Mn^{++} gives large transparent crystals (the min. concn. is 0.01–0.001 g. ion per l.; hydrolysis of $MnCl_2$ gives enough acidity but the optimum concn. of H^+ is 0.001 *N*; the best temp. is 40–60°). Pb^{++} acts similarly but the angles may be truncated (by 111). Sn^{++} and Cd^{++} give somewhat smaller transparent crystals. Nontransparent crystals are given by the following cations, in the order of size of crystals: $Ni^{++} > Cu^{++}$, Fe^{++}, Cr^{+++}, Tl^+, $Rb^+ > Fe^{+++}$, $Hg^{++} > Al^{+++}$. AUSTIN M. PATTERSON

Habit variation in crystals of barium and lead nitrates HAROLD E. BUCKLEY. *Z. Krist.* **76**, 147–68(1930)(in English).—The erratic choice of habit when $Ba(NO_3)_2$ crystallizes from soln. at const. temp. is traced to the effect of humidity on the rate of evapn. and to traces of $BaCO_3$. For $Ba(NO_3)_2$, the cube planes are increased (relatively to 111) by addn. of carbonates of Ba, Na, Ca, Mg and Fe, by $FeCl_3$, methylene-blue, Ba or Na manganate, Ba, Na or K permanganate, urea and Congo red. Cube planes are decreased by HCl, Ba, Na or K chlorate and perchlorate, safranine and quinine. The 210 planes are increased by $K_3Fe(CN)_6$ and $K_4Fe(CN)_6$, K and Ba chromate and $K_2Cr_2O_7$. For $Pb(NO_3)_2$ the cube is increased by Congo red, safranine, methylene blue; the cube is decreased by Na and K chlorates. Various theories concerning crystal habit are discussed. Observations on a large no. of crystals lead to the conclusion that the true symmetry of these nitrates is tetartohedral rather than pyritohedral. L. S. R.

The refractive indexes of mixed crystals of magnesium sulfate and zinc sulfate. MARY W. PORTER. *Z. Krist.* **75**, 288–300(1930)(in English).—In a series of mixed crystals of $MgSO_4.7H_2O$ and $ZnSO_4.7H_2O$ the variations of the principal *n*s were found to be directly proportional to the compn., as expressed in vol. or mol. percentage, or in percentage by weight. L. S. RAMSDELL

The dependence of crystal spacing on crystal size. J. E. LENNARD-JONES. *Z. Krist.* **75**, 215–6(1930)(in English).—From the theoretical standpoint, an actual increase in lattice dimensions is to be expected for min. crystals of the non-ionic type. For a crystal of 500 atoms, the increase should be 5%; for one 5 layers thick each way, 7%; for one 3 layers thick, 14%. This is because the total attractive field decreases relatively to the total repulsive field when particle size is decreased. For ionic crystals the reverse is the case. L. S. RAMSDELL

Absorption of synthetic spinels colored by chromium and manganese. K. SCHLOSSMACHER. *Z. Krist.* **75**, 399–409(1930); cf. *C. A.* **24**, 4482.—Absorption measurements with a photoelec. cell were made in the range 400 to 600 mμ on synthetic spinels ($MgO:Al_2O_3$ = 1:1) colored by both Cr and Mn. With relatively high Mn content the Mn absorption was superimposed on that of Cr. In the region 540 to 570 mμ there was absolute agreement with results obtained from a $KMnO_4$ soln.; elsewhere there was only occasional agreement. L. S. RAMSDELL

A powder spectrometric study of urea. R. W. G. WYCKOFF. *Z. Krist.* **75**, 529–37(1930).—Powder reflections combined with the best available estimates of at. *F*-values give satisfactory results. It would appear that this method is useful for simple org. crystals, instead of single-crystal spectrometry. For urea a unit cell was found with a = 5.670 A. U. and c = 4.726 A. U. At. positions are u_N = 0.14; v_N = 0.32; w_O = 0.57–0.58; t_N = 0.17. At. positions can be fixed with as great accuracy as that provided by Laue and spectral photographic comparisons involving more complicated planes. L. S. RAMSDELL

A determination of the molecular weight of methylbixin by means of x-rays. J. HENGSTENBERG AND R. KUHN. *Z. Krist.* **76**, 174–6(1930).—The unit cell has the dimensions a = 10.50 A. U., b = 17.59 A. U., and c = 13.4 A. U. (±0.05 A. U.). With 4 mols. in this unit, the calcd. mol. wt. indicates the formula $C_{26}H_{32}O_4$ rather than $C_{24}H_{30}O_4$ as proposed by Karrer (*C. A.* **23**, 4480). L. S. RAMSDELL

The crystal structure of the diphenylpolyenes. J. HENGSTENBERG AND R. KUHN. *Z. Krist.* **75**, 301–10(1930).—The unit cells of the diphenylpolyenes are: (monoclinic series) diphenylbutadiene a = 7.71 A. U., b = 11.70 A. U., c = 13.41 A. U., Z = 4; diphenylhexatriene 6.33 A. U., 7.43 A. U., 14.43 A. U., 2; diphenyloctatetraene 6.25 A. U., 7.44 A. U., 16.03 A. U., 2; (orthorhombic series) diphenyldecapentaene 10.25 A. U., 7.66 A. U., 21.2 A. U., 4; diphenyldodecahexaene 10.20 A. U., 7.60 A. U., 23.58 A. U., 4; diphenyltetradecaheptaene 10.2 A. U., 7.57 A. U., 25.95 A. U., 4. In every case the mol. wt. calcd. from x-ray data agrees with that from the structural formula. In the hexatriene and octatetraene there are definite *trans-trans* bindings. The mols. have a plane oblong shape. L. S. RAMSDELL

The structure of quinoid compounds and of a molecular compound of the quin-

hydrone type. EDUARD HERTEL AND GEORG H. RÖMER. *Z. physik. Chem.*, Abt. B, 11, 90–6(1930).—"Anthraquinone of the rhombic system contains 8 mols. in an elementary structure of only 3.95 A. U. height. The ring planes in this structure are parallel but on different levels In 2,7-dinitroanthraquinone (I) of the quadratic system, however, an elementary structure of 38.4 A. U. height contains 4 mols., the ring planes of which must be arranged perpendicular to each other. The mol. compd. I-fluorene (1.1, triclinic) possesses an elementary structure the dimensions of which preclude a lattice structure according to the tridimensional alternation principle."
G. TOENNIES

Determination of the melting point of platinum. G. RIBAUD AND P. MOHR. *Compt. rend.* 192, 37–8(1931).—The method used was the tube method already described for Pd (*C. A.* 24, 1006), the technic being improved by the use of a thermoelec. pile. By optical extrapolation, the m. p. of Au being used, the m. p. of Pt was calcd. as 1762°. The error in this value is probably not more than 2°. LOUISE KELLEY

The extent of dissociation of salts in water. II. Uni-bivalent salts. EDWIN C. RIGHELLATO AND CECIL W. DAVIES. *Trans. Faraday Soc.* 26, 592–600(1930); cf. *C. A.* 21, 3793.—Dissocn. was calcd. from cond. data by using the Onsager theory and assuming an intermediate ion. The values of K for the ions used are: $CdCl^+$ 0.0101, $PbCl^+$ 0.0304, $CaNO_3^+$ 0.521, $SrNO_3^+$ 0.150, $BaNO_3^+$ 0.121, $CdNO_3^+$ 0.394, $PbNO_3^+$ 0.0647, $LiSO_4^-$ 0.229, $NaSO_4^-$ 0.198, KSO_4^- 0.151, $AgSO_4^-$ 0.05 and $TlSO_4^-$ 0.0472. The transport numbers calcd. from these consts. agree with the exptl. A. F.

Notes on the specific gravities of liquid and solid sulfuric acid. D. MCINTOSH. *Proc. Trans. Nova Scotian Inst. Sci.* 17, 259–61(1930). H_2SO_4 from 60° to 66° Bé. can be kept almost indefinitely in solid CO_2 without crystn. The sp. gr. was measured in calibrated bulbs with graduated stems of capillary tubing.

60° Bé.	Temp.	Sp. gr.	66° Bé.	Temp.	Sp. gr.
Liquid	+15°	1.695	Liquid	+20°	1.838
	−40°	1.756		−78.5°	1.951
	−78.5	1.801			
Solid	−43°	1.797	Solid	-78.5°	2.040
	−60°	1.811			
	−78.5	1.838			

RACHEL BROWN

The chemical constant of hydrogen vapor and the entropy of crystalline hydrogen. T. E. STERN. *Proc. Roy. Soc.* (London) A130, 367–79(1931). From the Einstein-Bose statistics, the vapor pressure of cryst. H at low temp. is calcd. The chem. consts. of H vapor at low and ordinary temps., resp., are −1.11 and −3.70. The effects upon equil. of differences between the moments of inertia of gaseous and cryst. H are investigated. The entropies of cryst. para-H, ortho H and ordinary H at zero abs. are, resp., 0, $R \log 9$ and $\frac{3}{4} R \log 3 + R \log 4$. G. M. MURPHY

The thermal properties of ammoniates and analogous compounds and their use in absorption refrigerating machines. R. PLANK AND L. VAHL. *Forsch. Gebiete Ingenieurw.*, Ausgabe A., 2, 11–8(1931). Heats of reaction, heats of vaporization, vapor pressures, ds., and refrigerating capacities are discussed for the systems: (1) $CaCl_2.8NH_3 = CaCl_2.2NH_3 + 6NH_3$; (2) $CaCl_2.6CH_3NH_2 = CaCl_2.2CH_3NH_2 + 4CH_3NH_2$; (3) $LiCl.3CH_3NH_2 = LiCl + 3CH_3NH_2$; (4) $LiCl.2CH_3NH_2 = LiCl + 2CH_3NH_2$ The following new data are given for CH_3NH_2: vapor pressure, −77° to 9°, $\log p_{mm} = -\frac{2068.6839}{T} - 8.66437 \log T + 0.004785\, T$; C_p, liquid, at 20° = 0.77 g.-cal. per g. F. D. ROSSINI

Problems of present-day colloid chemistry. VII. H. R. KRUYT. *Chem. Weekblad* 27, 176–9(1930).—The phenomenon of lyotropy is discussed in the light of the differences of size of similar ions due to varying degrees of hydration: the greater the hydration of the ions, the less water is available for forming the stabilizing hydration layer of the colloidal particles, the conditions obtaining thus resemble those in a soln. of an org. substance, the soly. of which is depressed by the addn. of electrolytes. The manner in which the water mols. are oriented around the colloidal particles is also of importance. **VIII.** *Ibid* 241–4.—A survey of certain outstanding problems, including adsorption, thixotropy, gelatinization and the relationship of emulsions to true colloidal solns. B. C. A.

Heats of adsorption and their bearing on the problem of adsorption. H. R. KRUYT AND JOHANNA G. MODDERMAN. *Chem. Reviews* 7, 259–346(1930).—A thorough review of the exptl data on heats of adsorption is given. An equation is deduced for calcn. of

the isothermal heats of adsorption. Calcd. and observed results agree fairly well. Complete agreement is not to be expected. The state of the adsorbed phase is discussed critically. Each of the equations now in use in connection with adsorption has a domain of usefulness but none of them expresses a complete isotherm at lower temps. Eight factors that influence adsorption are listed. One equation cannot include all of them. Many heats of adsorption are tabulated. Complete bibliography. L. H. R.

Adsorption of chromate ions by colloidal aluminum hydroxide. BEN H. PETERSON AND KEITH H. STORKS. *J. Phys. Chem.* 35, 649–52(1931); cf. *C. A.* 24, 1008.—The adsorption of K_2CrO_4 by colloidal Al_2O_3 was detd. at concns. above and below the pptn. value. Three types of adsorption curves result, representing (1) neutralization of the pos. charge on the suspended particle, (2) surface adsorption not elec. in type and (3) a combination of 1 and 2. It is not always permissible to extrapolate data to zero concn. of the adsorbed substance. HARRY B. WEISER

Adsorption of titanium hydroxide sol. L. S. BHATIA AND S. GHOSH. *J. Indian Chem. Soc.* 7, 687–97(1930).—$Ti(OH)_4$ sol was prepd. by dropping $TiCl_4$ slowly into water at 18°. The sol cannot be completely freed from HCl by dialysis. A sol contg. 15.2 g. TiO_2 per l. was found on prolonged dialysis to become more and more viscous and as soon as the acid concn. fell to p_H 4.1 the whole mass coagulated as a gelatinous ppt. The sol adsorbed appreciable amts. of anions from solns. of Na and K salts. The order of adsorption expressed as g.-mol. per g. of adsorbent was found to be $Fe(CN)_6^{---} > NO_3 > SO_4 > Cl > S_2O_3 > Cr_2O_7 > Br > Fe(CN)_6^{----} > IO_3 > CrO_4 > OH$. The coagulating power of the anions was found to be in the following decreasing order $Fe(CN)_6^{----} > Fe(CN)_6^{---} > OH > SO_4 > Cr_2O_7 > CrO_4 > IO_3 > S_2O_3 > NO_2 > Cl > Br$. Strong adsorption does not always indicate high coagulating power in this sol. The adsorption of OH ions by this Ti sol was small. The high coagulating power of OH ions was due to the removal of the stabilizing H ions. The sol adsorbed more anions than cations with the liberation of OH ions and a corresponding increase of p_H. $Ti(OH)_4$ is more basic than acidic. On aging, the sol prepd. at 18° became stable toward electrolytes and showed a decrease in sp. cond. and viscosity. A sol. prepd. at 55° did not change in stability on aging and the sp. cond. and viscosity increased very slightly. Adsorption of Ti^{++++} by the sol prepd. at 18° accounts for its stability. L. H. REYERSON

Studies on electrokinetic potentials. VII. The temperature coefficient of the ζ-potential. HENRY B. BULL AND ROSS AIKEN GORTNER. *J. Phys. Chem.* 35, 456–66(1931); cf. *C. A.* 25, 1138.—The temp. coeffs. of the ζ-potential for the interfaces water-cellulose, 1×10^{-4} *N* NaCl-cellulose, and EtOH-cellulose were measured between 20° and 51°. The latter interface potential has a pos. temp. coeff., while the other 2 show a slight max. in the neighborhood of 40°. MALCOLM DOLE

Structure of thin films formed from solutions of crystallizing and non-crystallizing substances. G. TAMMANN AND H. ELSNER VON GRONOW. *Z. anorg. allgem. Chem.* 194, 268 72(1930).—The surface films formed by evapn. of solns. contg. soaps or similar substances were studied by interference colors. Perrin (*C. A.* 24, 3411) found that the local thickness of a Na oleate film varies by steps of 4.2μμ. This observation was confirmed, and the same formation of flows with step-structure was observed for films of K undecylate and K myristate. Among a considerable no. of substances which were investigated, the phenomenon occurred only with Na and K salts of higher fatty acids. It is suggested that besides an elongated form of the mols., a film capable of swelling is required. L. ONSAGER

Experiments with precipitated and colloidal manganese dioxide. JNANENDRANATH MUKHERJEE, SATYAPRASAD ROY CHOUDHURY AND M. R. SUBBA RAO. *J. Indian Chem. Soc.* 7, 803-13(1930).—The results of adsorption, antagonism and coagulation expts. with both pos. and neg. MnO_2 sols and of adsorption expts. with negatively pptd. MnO_2 conflict in many respects with the findings of Dhar and his co-workers (*C. A.* 21, 3005; 22, 1075). Further study is needed to reveal the true chem. nature of the particles in these sols. OSCAR T. QUIMBY

A critical study of Kohlschütter's method of preparing silver hydrosol. M. RAMAN NAYAR AND P. S. MACMAHON. *J. Indian Chem. Soc.* 7, 699-707(1930).—The presence of alkali ions is not essential in the formation of a Kohlschütter sol as stated by Pauli, *C. A.* 18, 2629. The walls of the exptl. vessels det. the nature of the sol. Silvered vessels produce no sol. or only thin, pale, white, unstable sols. Silica or glass vessels invariably give rise to wine-red, stable sols. The contradiction between Pauli's results and those of N. and M. is traced to the neg. catalytic effect of the Ag vessels used by Pauli. Stable Kohlschütter sol was prepd. at 85°. Reduction of Ag_2O soln. near the b. p. produces a coarse suspension. L. H. REYERSON

Regarding the colloidal nature of cuprammonium solution. ALFRED J. STAMM.

J. Phys. Chem. **35**, 659–60(1931).—It was demonstrated by the aid of the ultracentrifuge that cuprammonium solns. contain colloidal material, probably $Cu(OH)_2$. The sol is polydisperse, contg. particles ranging in diam. from 6.5 mμ to more than 20.0 mμ for the concns. investigated. HARRY B. WEISER

Micelles and base exchange. MERLE RANDALL AND JESSIE Y. CANN. *Chem. Reviews* **7**, 369–406(1930).—Micelles are considered intermediate steps between ordinary ions and solid crystals. The soln. of micelles is taken to be a homogeneous phase and the thermodynamics of such a system is therefore that of a homogeneous phase rather than that of a heterogeneous system. The theory of the formation of micelles is extended to very large aggregates. The electrolytic nature of cryst. and near cryst. micelles is considered and the activity coeff. of such cryst. micellar masses is shown to be practically zero. All substances forming neg. micelles in soln. should possess differential base-exchange properties. Base exchange in zeolites, the compn. of zeolites and the methods of prepg. artificial zeolites are discussed. In zeolites the neg. ions of the aluminosilicate are considered to form large micelles. The rapid base or acid exchange properties of solid solns. and those of zeolites are explained by the electrolytic nature of the solids. Base exchange is considered in other systems as well as in zeolites. L. H. REYERSON

Mechanism of the mutual coagulation process. HARRY B. WEISER AND THOMAS S. CHAPMAN. *J. Phys. Chem.* **35**, 543–56(1931).—The zone of complete mutual coagulation of 2 sols of opposite sign may be very narrow or quite broad. When a given series of pos. sols, *e. g.*, is arranged in order of the optimum concn. for mutual coagulation on mixing with neg. sols, the order of the pos. sols may vary widely with different neg. sols. The reason for this behavior is that the mutual pptg. power is not detd. exclusively by the charge on the particles. Other factors are (*1*) mutual adsorption of colloidal particles that is independent of the charge, (*2*) the presence of pptg. ions as impurities and (*3*) interaction between stabilizing ions. The latter factor is not a general cause of mutual coagulation but it may be important in certain cases. The investigations were carried out with the following sols: (*a*) positively charged: Fe_2O_3, Cr_2O_3, CeO_2, $BaSO_4$, Night blue; (*b*) negatively charged: SnO_2, $Zn_2Fe(CN)_6$, $Cu_2Fe(CN)_6$, Congo red, As_2S_3. H. B. W.

A contribution to the theory of thixotropy. E. A. HAUSER. *J. Rheol.* **2**, 5–9 (1931).—The particles of a sol added to a bentonite dispersion do not come into close contact with the particles of the latter but rebound while at some distance away. The effect is due to the formation of solvated hulls around every particle. The view that each mech. disturbance disrupts certain solvatized hulls, thereby lessening the viscosity, is widely held but it is untenable, because there is no change in vol. On the other hand, thixotropy is characteristic of anisotropic particles; in extreme cases, of scale-like particles. The actual setting of the gel is an instantaneous effect of orientation and not a continuous change from liquid to solid. EUGENE C. BINGHAM

Lyophilic colloids. I. Hydration. S. M. LIPATOV AND L. N. KOROBOVA. *Z. anorg. allgem. Chem.* **194**, 369–76(1930).—The substance used in these expts. is "geraninic" acid, $C_{24}H_{17}N_3O_4S_2$. In dil. aq. solns. it is slightly ionized, as shown by a small elec. cond. The mol. wt. found from diffusion expts. is 506; the theoretical value is 497. The mol. wt. calcd. from cryoscopic measurements varies with the concn. and is lower than the theoretical value. The failure of geraninic acid to dialyze (nature of membrane not given) indicates hydration. The ability of "true" solns. of geraninic acid to gelatinize at low temp. is further evidence of its hydration. Osmotic pressure detns. on solns. contg. 2–25 g. per l. show that 1 g. geraninic acid holds 31 g. H_2O. Viscosity detns. on sols contg. 0.175 to 1.40% geraninic acid indicate a similar high hydration. Both the viscosity and the osmotic pressure of geraninic acid dispersions are greatly lowered by the addn. of small quantities (0.25–1.00%) of tannic acid. **II. Theory of macro- and micro-syneresis.** *Ibid* 377–82.—Geraninic acid gels show a much larger syneresis in 0.1 *N* NaCl than in H_2O alone. The time required for the complete syneresis decreases as the concn. of geraninic acid increases. The velocity of syneresis is a function of the distance between particles and depends upon the intensity of the attractive forces, which are the same in all directions. The velocity of syneresis follows the law of the first-order reaction. The concn. of geraninic acid in the liquid squeezed out is independent of the gel concn. When the vol. of the disperse phase is just equal to the total vol. of the system, no syneresis is observed; the addn. of more geraninic acid breaks up the structure of such a gel because of partial dehydration. The elec. charge is the only true stability factor of lyophilic systems. Hydration merely delays the changes. Also in *J. Russ. Phys. Chem. Soc.* **62**, 1895–1906(1930). OSCAR T. QUIMBY

Hysteresis in sol-gel transformations. S. N. BANERJI AND S. GHOSH. *Z. anorg.*

allgem. Chem. **194**, 305–15(1930).—By finding the time required at various temps. for (*1*) a sol to solidify completely and (*2*) the corresponding gel to become completely fluid, time-solidification and time-liquefaction curves were obtained. These curves tend to coincide, *i. e.*, the solidification and the liquefaction temp. approach each other more closely, the greater the time that is allowed. Such curves were obtained for: Na palmitate and Na stearate in H_2O, MeOH, EtOH, PrOH, BuOH; Na valerate, Na caproate and gelatin in H_2O. If the hysteresis is expressed as the temp. difference between the solidification and the liquefaction curves at 12 min., it was found that, in most cases, the hysteresis decreases abruptly to a min., rises again abruptly to a max. and then gradually decreases with increasing concn. of colloid. Addn. of NaOH to the Na palmitate or stearate systems decreases the hysteresis. Small concns. of alkali-metal chlorides peptize and larger concns. coagulate Na palmitate sols. Small concns. of both KCl and NaCl decrease the hysteresis. The hysteresis is also reduced by inoculation (of a cooling sol) with gel of the same concn. or by shaking the container. The partial analogy with crystn. from supersatd. soln. is pointed out. The hysteresis is probably due to the low orientation velocity of the micelles. OSCAR T. QUIMBY

Diffusion rings of silver dichromate and chromate in gelatin and agar-agar. F. PANNACH. *Chem. Erde* **4**, 598–631(1930).—A continuation of the work of Linck (*C. A.* **23**, 5380) on the rates of diffusion of $K_2Cr_2O_7$ or K_2CrO_4 and $AgNO_3$ in gelatin, etc., and on the form of the resulting ppts. B. C. A.

The distribution of ions in gels. E. J. BIGWOOD. *Trans. Faraday Soc.* **26**, 704–23 (1930); cf. *Compt. rend. soc. biol.* **104**, 815(1930).—The diffusion of OH ions from a const. concn. of NaOH into agar gels contg. phenol red was measured by the level at which the p_H was 7.5. The rate of diffusion increases slightly toward the bottom of the gel column, but in general the distance of penetration, d, in time $t = k\sqrt{t}$. With gelatin gels, however, the OH ion produces swelling which results in a concn. gradient of gelatin in the gel, and hence of the OH ion, the effect varying with concn. of the gel (Stiles, *C. A.* **17**, 2378). A steady state is reached only after some months, and the gradient equil. involved is that given by Donnan (*C. A.* **24**, 3416). When the concn. of OH ion above the gelatin is reduced, the p_H 7.5 level rises to a new equil. position. With 0.01 *N* $CaCl_2$ and 8% gelatin blocks, Ca migrates into the gel at $p_H > 4.7$, and Cl at $p_H < 4.7$, the Donnan equil. relationship for the whole block holding within 5%, although the electrolyte is unevenly distributed in the gel. K. V. THIMANN

Alkaloid precipitation reactions in gels. BENGT JONSSON. *Svensk Farm. Tids.* 35, 25–9, 45–9(1931).—Alkaloid solns. on gels in tubes contg. a neutral pptg. reagent give cryst. colonies characteristic as to cryst. form, aggregate and gel penetration. Gels from $Na_2Si_4O_9$ are easily made from material readily available pure, stable and chemically inert. Five cc. 20% $Na_2Si_4O_9$, 8 cc. *N* H_3PO_4 and 1 cc. neutral reagent (*e. g.*, trinitrophenol) form a gel in about 30 min. Two cc. alkaloid soln. is placed on the gel and the tube set aside for 1 or 2 days. Measurements must be made with care since slight variations make large differences. *E. g.*, 6.2 cc. *N* HCl to 5 cc. 20% silicate soln. made up to 13 cc. with water gels in 1 min. but 7 cc. acid to 4 cc. Si soln. requires many months; 6.5 cc. acid to 5.5 cc. silicate gives a gel in 20 min. A. R. ROSE

The behavior of proteins toward colloids and toward electrolytes. W. PAULI. *Trans. Faraday Soc.* **26**, 723–37(1930).—A summary is given of P.'s work on the coagulation of proteins and of Al_2O_3 sols by colloids and salts. In continuation of the work of Pauli and Weiss (*C. A.* **23**, 1551) it is shown that mutual flocculation of Congo blue and pure albumin sols occurs at approx. equal concns. of particles. With lower protein concns., the color change blue to red on heating becomes irreversible on cooling, because of the assocn. of the N atoms of the dye with COO groups of the protein, resulting in conversion of NH_3^+ to NH_2 and hence color change. There is also assocn. of the NH_3^+ groups of the zwitterionic protein with SO_3H groups of the dye. At still lower protein concns. flocculation is obtained by passing in CO_2, when 10 dye particles are assocd. with 1 serum-albumin particle. A flocculation diagram for NaCl, Congo blue sol, and albumin is given. Protective action, which does not occur with electrolyte-free sols, is attributed to inactivation of the charge on the dye by the salt soln. Sensitization is due to action of the salt at low concn. on the aggregates of protein and dye already formed. The protective action and the irreversible color change can be imitated with glycine instead of protein, since only zwitterionic structure is essential, but flocculation and sensitization, which involve large multivalent nuclei, are not obtained.
K. V. THIMANN

Preparation of cellulose membranes containing proteins. JEAN LOISELEUR AND LÉON VELLUZ. *Compt. rend.* **192**, 43–5(1931); cf. *C. A.* **25**, 1546.—Solns. of gelatin in

glacial AcOH, or of other proteins in anhyd. HCOOH, are miscible in all proportions and without flocculation with solns. of cellulose acetate (I) or nitrate in AcOH; these acid proteocellulose solns. remain stable during evapn. The membranes formed may be regarded as true solid solns., the structure of which depends on the ratio protein:cellulose. A 10% soln. of gelatin in cold glacial AcOH is first prepd. According to the percentage of gelatin desired in the membrane (the percentage may vary from 5 to 75), a suitable quantity of this soln. is mixed with a 10% soln. of I in AcOH. The mixt. is shaken energetically, and the membrane prepd. as usual. If the drying is complete, a resistant membrane is obtained, the permeability of which depends on the condition of evapn. of the original soln. Membranes with 5% gelatin are transparent; those with 25% are opalescent. The preceding method is applicable to the prepn. of membranes contg. other proteins, except that anhyd. HCOOH must be used to dissolve the protein. A perfectly dry membrane contg. 20 parts casein to 80 parts dry I is clear and does not give the Tyndall effect. Using the method described, a series of membranes contg. egg albumin, gliadin and the proteins of serum were prepd. LOUISE KELLEY

Solubility of thallous iodate in ethyl alcohol–water mixtures. VICTOR K. LA MER AND FREDERICK H. GOLDMAN. *J. Am. Chem. Soc.* 53, 473–6(1931).—The application of Born's equation for the electrostatic work of transfer of charged spheres of av. radius r was tested with $TlIO_3$-alc.-water mixts. The soly. of $TlIO_3$ was measured in EtOH-water mixts. contg. 0–47% EtOH. From the data, the av. radii were calcd. compared with the values of the parameter "a" computed from soly. data in dil. salt solns.

ALLEN S. SMITH

Liquid ammonia as a solvent and the ammonia system of compounds. VII. The nature of free radicals, their preparation and properties, as revealed by studies in liquid ammonia solutions. WARREN C. JOHNSON AND W. CONARD FERNELIUS. *J. Chem. Education* 7, 2600-8(1930); cf. *C. A.* 24, 3486.—Kraus classified free radicals on the basis of their affinity for the electron into strongly electropos., strongly electroneg. and amphoteric. The strongly electropos. radicals include the tetraalkylammoniums, which behave like typical alkali metals; *i. e.*, they give blue solns. in liquid NH_3 and form amalgams. The RHg radicals exhibit metallic properties. The strongly electroneg. radicals include $(CN)_2$, $(OCN)_2$, $(SCN)_2$ and $(SCSN_3)_2$. They do not exist in the monomol. state and they behave chemically like the halogens. Among the amphoteric radicals are Ph_3C, Me_3Sn and Me_2Sn. These substances combine with both the strongly electropos. and strongly electroneg. elements. Liquid NH_3 is a suitable solvent for the prepn. and study of the amphoteric free radicals because many of the substances from which the radicals are prepd. are sol. in liquid NH_3 and do not react with it. Typical reactions in liquid NH_3 are: $Me_3SnCl + 2Na \longrightarrow Me_3SnNa + NaCl$; $Me_3SnNa + Me_3SnCl \longrightarrow 2Me_3Sn + NaCl$; $Me_2SnBr_2 + 2Na \longrightarrow 2NaBr + Me_2Sn$.

W. C. FERNELIUS

The connection between ionic mobility and diffusion velocity in solid salts. CARL WAGNER. *Z. physik. Chem.*, Abt. B, 11, 139–51(1930).—For mixed crystals of solid salts of AgI + CuI or $PbCl_2$ + $PbBr_2$ a formula is derived to calc. the diffusion coeffs. of the ions from conductivities and transference nos. or from the migration velocities of the ions. From the conductivities of pure solid salts with exclusive cationic or anionic conductivities the self-diffusion const. of the more mobile ion can be derived. The formulas used by Hevesy (*C. A.* 15, 3243, 1440; 22, 1711; 23, 3395; 24, 1573) and by Tubandt, Reinhold and Jost (*C. A.* 22, 342; 23, 3612) are confirmed. It is assumed that the single ions move practically independently of each other (no common migration of cation and anion, no exchange of places between adjoining cations or anions). Approx. exptl. verification of the derived formula confirms this assumption. G. T.

The temperatures of maximum density and the surface tensions of aqueous solutions in relation to concentration. G. TAMMANN AND A. ROHMANN. *Z. anorg. allgem. Chem.* 194, 273–7(1930); cf. *C. A.* 23, 19.—The changes of the temp. of max. d. t_m and of the surface tension σ effected by addn. of different substances to water are discussed from the viewpoint of internal pressure. Solutes of high internal pressure cause a marked decrease of t_m, directly proportional to concn. Solutes of low internal pressure cause a smaller decrease of t_m, occasionally preceded by an increase at low concns., and the decrease is always smaller (particularly at low concns.) than the amt. calcd. by assuming the thermal expansion curves of water and solute additive. The difference is attributed to the internal soln. pressure's (K) being smaller than that of water, which affords a basis for the calcn. of K. It is pointed out that $\Delta\sigma/\Delta x$ (x = concn.) has the same sign as $\Delta K/\Delta x$. For substances of high K, $\Delta\sigma/\Delta K$ ranges between 13 and 72, while for substances of low K, $\Delta\sigma/\Delta K$ takes values in the range 5000–70,000. This contrast is connected with the well-known fact that substances lowering σ, which conc.

in the surface layer, effect a much greater abs. change than those that tend to keep away from the surface, raising σ. L. ONSAGER

Viscosity of electrolytes. W. E. JOY AND J. H. WOLFENDEN. *Nature* **126**, 904–5 (1930).—The viscosities of dil. aq. solns. of KCl were measured at 18° in both silica and glass viscometers. The results in glass indicate viscosities greater than that of pure water for concns. up to 0.025 *N*. When extrapolated to zero concn. the curve agrees with the predictions of the Dole-Falkenhagen equation. The results with the silica viscometers are less concordant but agree in general with those with glass. W. W. STIFLER

The measurement of electrolytic resistance by the barretter method. J. SCHIELE AND M. WIEN. *Ann. Physik* [5], **7**, 624–32(1930).—An oscillating circuit of 10,000–100,000 hertzes is connected to a barretter for measuring resistance of electrolytic solns. The barretter is a d. c. bridge that is shielded from the high-frequency circuit with choke coils and condensers. The effects of increase in the applied potential, of strong and of loose coupling, and of thin and of thick platinizing of the electrodes are shown. The limit of precision with the Kohlrausch method, using a telephone, is 30 sq. cm. ohm; by the barretter method, 1 sq. cm. ohm. G. M. MURPHY

The measurement of the conductance of electrolytes. III. The design of cells. GRINNELL JONES AND GILES M. BOLLINGER. *J. Am. Chem. Soc.* **53**, 411–51(1931); cf. *C. A.* **23**, 4613.—Data are given that confirm the observation of Parker (*C. A.* **17**, 2382, 3440) that the ratio of the resistance of 2 conductance cells when filled with a common soln. is not independent of the sp. conductance of the soln. used. In addn. to the error due to polarization, there is a capacitative shunt between parts of the cell of opposite polarity which makes the measured resistance too low. New cells are designed which give results reliable within 0.01%. JOHN R. HILL

Conductivity measurements and titrations. A contribution to their technic. FRIEDRICH L. HAHN. *Z. Elektrochem.* **36**, 989–91(1930).—A Cu–Cu_2O–Pb detector is used as a rectifier and a galvanometer as a null-instrument in cond. measurements. The method is fast and accurate and is especially adaptable to titrations. H. F. J.

Reduction potential of quadrivalent to tervalent iridium in hydrochloric acid solution. SHO-CHOW WOO. *J. Am. Chem. Soc.* **53**, 469–72(1931).—The reduction potential at 25° is 1.021 v. for the reaction $IrCl_6^{---} = IrCl_6^{--} + E^-$. The solns. were 0.1 *f* in HCl and the concns. of the 2 ions of the reaction between 0.002 and 0.008 *f*. The free energy decrease is —23,540 cal. and the temp. coeff. between 25° and 20° is +0.00098 v. per degree, which makes ΔH = —30,400 cal. JOHN R. HILL

The electrolytic reduction of acid solutions of vanadium. F. FOERSTER AND F. BÖTTCHER. *Z. physik. Chem.*, Abt. A, **151**, 321–400(1930).—The purpose of this investigation was to find out to what degree the reduction of V solns. is similar to solns. of Mo. E. m. f. measurements were made on equal mixts. of V solns. of different states of oxidation at various acid concns., with electrodes of Pt, Ir and Au. On platinized electrodes the first stage of reduction runs smoothly, but the second stage encounters considerable polarization so that H may be evolved. On bright Pt the first stage of reduction forms a diaphragm on the cathode, thereby producing polarization. As was the case with Mo this diaphragm consists of difficultly sol. products of hydrolysis. Au cathodes act similarly to Pt ones. MALCOLM DOLE

An effect of the breadth of junction on the electromotive force of a simple concentration cell. GEO. SCATCHARD AND T. F. BUEHRER. *J. Am. Chem. Soc.* **53**, 574–8 (1931).—The e. m. f. of HCl concn. cells increased a few hundredths of a mv when the liquid junction was made very thin. Flowing junction electrodes were used. This increase is greater than would be calcd. from the Debye-Hückel theory and is probably caused by the change in temp. in the boundary layer resulting from the heat of mixing of the 2 solns. JOHN R. HILL

The quinhydrone electrode. I J. LIVINGSTON R. MORGAN, OLIVE M. LAMMERT AND MARGARET A. CAMPBELL. *J. Am. Chem. Soc.* **53**, 454–69(1931).—A comprehensive study of the quinhydrone electrode was made to det. its reproducibility in 0.1 *N* HCl under different conditions. Flaws in metal electrodes were the sources of the greatest error. A method of making, cleansing and testing these which minimizes breakage is described. The effect of the size, compn., form, condition and age of the metal electrodes, with and without the use of Hg as a connecting medium, is reported. The purity and amt. of quinhydrone do not appreciably affect the results if the concn. is not too low. Stirring the solns. is recommended when feasible. II. OLIVE M. LAMMERT, J. LIVINGSTON R. MORGAN AND MARGARET A. CAMPBELL. *Ibid* 597–604.—The effect of N on the reproducibility of the quinhydrone electrode in 0.1 *N* HCl was detd. Better results

were obtained when N was passed through the solns. Equil. was attained more rapidly with electrodes prepd. with N than with air. F. W. MARSH

Effect of various manganese compounds on the quinhydrone electrode. S. OSUGI AND H. KASHIHARA. *J. Sci. Soil and Manure* 3, 4(1929); *Proc. Intern. Soc. Soil Sci.* 5, 104(1930). The presence of oxides of Mn (MnO_2 and Mn_3O_4) in small proportions (0.001 and 0.005%, resp.) caused inaccuracies in p_H measurements with the quinhydrone electrode. In soils known to contain Mn, however, no significant differences in p_H values as dtd. by H and quinhydrone electrodes were observed. B. C. A.

The potential of the cadmium electrode. FREDERICK H. GETMAN. *J. Phys. Chem.* 35, 588 95(1931).—Single crystals of Cd function as const. and reproducible electrodes, but give potential values that are uniformly greater than electrodes of the polycryst. form. A recalcn. of the normal electrode potential of Cd gives the value, $E_0 = 0.395$ v. MALCOLM DOLE

The potential of passive iron. A. TRAVERS AND J. AUBERT. *Compt. rend.* 192, 161–3(1931).—The e. m. f. of Fe in Na_2SO_4 solns. of different p_H values and in various oxidizing agents was dtd. The values vary considerably with the conditions and time, finally becoming const. There are degrees of passivity and the oxide-film theory is not generally applicable. V. F. HARRINGTON

The passivity of chromium. I. ERICH MÜLLER AND O. ESSIN. *Z. Elektrochem.* 36, 963–72(1930).—Electrolytic Cr is passive at 0° in *N* HCl, HF, HBr, H_2SO_4, $HClO_4$, H_3PO_4 and HNO_3. In the first 4 of these acids the metal becomes active when the acid is warmed, and each acid has a definite characteristic activation temp. that is proportional to the diam. of its anion. In $HClO_4$ and H_3PO_4 the metal is not active at 100°. Passive Cr is made more noble by removal of adsorbed H, but when placed in the inactive acids the potential gradually rises with time until it is greater than the reversible H potential, without the loss of its passivity by the Cr. When Cr is cathodically polarized in inactive acids (except H_3PO_4) it suddenly becomes active at a definite potential and the potential increases immediately to that of the Cr/Cr^{++} equil. The passivity of Cr is due to a layer of oxide, the pores of which are permeable to certain anions. H. F. JOHNSTONE

Atomic reactions that are affected by inertia. H. v. HARTEL AND M. POLANYI. *Z. physik. Chem.*, Abt. B, 11, 97 138(1930); cf. *C. A.* 22, 900. –The reaction of Na vapor with alkyl halides is accompanied by, at most, only a trace of luminescence. To show the dimensions of the Na alkyl halide flame a Na-A "resonance" lamp was used. N_2 or H_2 was used as the inert gas for the combustion. The diam. of the flame is inversely proportional to the square root of the pressure of alkyl halide and at controlled pressures serves to measure the speed of reaction. With MeI reaction is practically instantaneous. With MeF it is slow and could not be measured. Series were also obtained with Na in Br_2, the speed being greater than with MeI. The same relative order is obtained with PhCl, PhBr and PhI. Substitution of more halogens on a C increases the speed of reaction. Substitution of other groups for H increases the rate of reaction. The heats of activation of MeBr (3 cal.), MeCl (8 cal.), MeF(>20 cal.), can be correlated with London's theory, but that of $(CN)_2$ cannot. The reaction of Na vapor with ClCN tends to form NaCl instead of NaCN with increase of temp. The free CH_3 liberated in these reactions with alkyl halides reacts with H_2 at 300–500° to give CH_4 and H. FOSTER D. SNELL

The reaction mechanism of the formation of hydrogen molecules from atoms. H. SENFTLEBEN AND O. RIECHEMEIER. *Physik. Z.* 31, 960–1(1930); cf. *C. A.* 24, 2033, 4980.—If $a = c_1 n_a + c_2 + (c_3/n_a)$ (n_a = no. of atoms; c_1; c_2; c_3 = consts.) then a must be a linear function of n_a, if the surface reaction can be suppressed. This was found to be the case. The values of c_2 at 60, 30 and 15 mm. Hg were detd. and the conclusion was reached that space collisions between 2 atoms and 1 mol. preponderate. The at. collision diam. was found to be 3.5 times as great for tri-at. collisions as for collisions between 2 atoms and 1 mol. In the latter case, the collision diam. is only slightly larger than the gas-kinetic one. FRANK URBAN

Kinetics of the polymerization of ethylene at pressures above one atmosphere. ROBERT N. PEASE. *J. Am. Chem. Soc.* 53, 613–9(1931).—The rate of polymerization of C_2H_4 was measured at 2.5, 5 and 10 atm. from 350° to 500°. Fifty % of the C_2H_4 may be polymerized to gaseous and liquid monoolefins without formation of more than 2% of H_2 and satd. hydrocarbons. Butylene is concluded to be the primary reaction product. The reaction is of the second order and has an abnormally low temp. coeff. The mechanism of the assocn. reaction is discussed. S. LENHER

Polymerization and thermal decomposition of acetylene. P. SCHLÄPFER AND M. BRUNNER. *Helv. Chim. Acta* 13, 1125–51(1930).—Polymerization of C_2H_2 begins at

300°, but does not become rapid until 450°. Uncatalyzed spontaneous decompn. occurs only above 500°. Polymerization was carried out in glass tubes and the reaction velocity at various temps. was measured by the decrease in pressure that accompanies polymerization. At 420° the pressure decreased 110 mm. in 0.5 hr. and 590 mm. in 5 hrs., when gas analysis showed that 71.5% of the C_2H_2 had disappeared. Polymerization proceeds in the homogeneous phase and the reaction probably is bimol. Increased glass surface (10-100 times) has little effect on the reaction velocity, but catalysts such as Cu accelerate, while Fe powder or C (from C_2H_2) retards decrease in pressure. Polymerization products could not be isolated. The temps. and pressures at which explosive spontaneous decompn. of C_2H_2 takes place were detd. Below 530°, no deflagration occurs at pressures under 3 atms.; at higher temps. it takes place under much lower pressures (as 700° and 0.6 atms.). C, Fe and Fe oxide speed the relatively slow non-explosive decompn. but retard the explosive decompn. especially at higher temps. Although deflagration occurs as low as 590° at approx. 1000 mm. in the absence of C and Fe, in their presence it does not occur at 1960 and 2400 mm., resp. Impurities usually present in crude C_2H_2 have no appreciable effect on the spontaneous decompn., but the presence of small quantities of O causes deflagration at much lower temps. With increasing amts. of O, explosive decompn. occurs less readily and spontaneous combustion (oxidation) more readily. A. WIEBEN

The thermal decomposition of nitrogen pentoxide at low pressures. J. H. HODGES AND E. F. LINHORST. *Proc. Natl. Acad. Sci.* **17**, 28-32(1931).—Previous detns. of this rate gave conflicting results. The rate was detd. at 35° and at pressures from 0.12 to 0.001 mm. The reaction is unimol. above 0.06 mm. partial pressure of N_2O_5. Below this the rate decreases with the pressure, and below 0.004 mm. the reaction appears to be bimol. V. F. HARRINGTON

Equilibrium diagrams of the aluminum-manganese, copper-manganese and iron-manganese systems. TORAJIRO ISHIWARA. *Science Repts. Tôhoku Imp. Univ.* 19, 499-519(1930).—By thermal analysis, elec. resistance measurements, dilatometric and magnetic analyses, new and corrected equil. diagrams of the Al-Mn, Cu-Mn and Fe-Mn binary systems are set forth. Fifty-six photomicrographs are reproduced. CURTIS L. WILSON

The equilibrium iron-iron carbide-oxygen. P. PINGAULT. *Compt. rend.* **192**, 45-7(1931).—The Fe-C-O diagram is completed by detg. the curve representing the equil. between Fe and Fe_3C in mixts. of CO and CO_2. In the app. used the gas was passed continuously through a closed circuit. The 50-cc. samples were analyzed chemically with an accuracy of more than 0.5%. The Fe was used in the form of fine wire which made it possible with a small wt. of material to fill the whole tube and obtain a rather large reaction surface. The expts. were carried out at atm. pressure. To insure having no false equil. due to passive resistance, Fe was carburized in a mixt. rich in CO and decarburized in a mixt. rich in CO_2. Analysis showed that the 2 methods gave the same results at the same temp. When a mixt. of Fe and C was kept in a limited quantity of O the results varied with the temp.: above 740° Fe_3C was formed and CO_2 in the gaseous phase varied from 0 to 28%; between 740° and 700°, the proportion of CO_2 was 28-42%, and Fe_3C was oxidized to Fe and CO; below 700° the content of CO_2 became sufficient to oxidize Fe. The following calcns. were made: between 700° and 1000°, $CO_2 + Fe_3C \rightleftarrows 3Fe + 2CO - 14.5$ cals.; $3Fe + C \rightleftarrows Fe_3C - 27.5$ cals. L. K.

Notes on catalysis. A. BEYER. *Tiba* **8**, 1287-97(1930).—A general review of catalytic reactions, enumerated in chronological order, and of the various theories which have been proposed to explain catalysis. A. PAPINEAU-COUTURE

The heat capacities at low temperatures of manganese sulfide, ferrous sulfide and calcium sulfide. C. TRAVIS ANDERSON. *J. Am. Chem. Soc.* **53**, 476-83(1931).—Heat capacities were detd. for MnS, FeS and CaS between 60° and 300°K. The values obtained for entropy are compared with related thermal data found in the literature. R. H. LAMBERT

The heats of combustion of methane and carbon monoxide. FREDERICK D. ROSSINI. *Bur. Standards J. Research* **6**, 37-49(1931).—With the app. that was used in detg. the heat of formation of water, the heats of combustion of CH_4 and CO were measured. For 25° and a const. pressure of 1 atm., the values per mole are, resp., 890,160 ± 300 and 282,890 ± 120 international joules; 212,790 ± 70 and 67,623 ± 30 g. $cal._{18}$. F. D. ROSSINI

The heat of mixing in molten metals. MASUO KAWAKAMI. *Science Repts. Tôhoku Imp. Univ.* **19**, 521-49(1930).—A continuation of previous expts. (cf. *C.* **1**. **22**, 718). With similar or slightly modified app. 25 binary systems were investigated. The at. heats of mixing for 12 systems having intermetallic compds. existing up to the

liquidus were without exception pos. and reached a max. at the compn. of the compd. as given: Sn–Mg (at 800°), value of $Q_{max.}$ = +3420 cal. for 63.3 at. % Mg; Bi–Mg (800°), $Q_{max.}$ = +3050 cal., 55.4 at. % Mg; Pb–Mg (800°), $Q_{max.}$ = +2410 cal., 61.6 at. % Mg; Zn–Mg (800°), $Q_{max.}$ = +1520 cal., 39.5 at. % Mg; Cd–Sb (800°), $Q_{max.}$ = +829 cal., 46.7 at. % Sb; Mg–Al (800°), $Q_{max.}$ = +1130 cal., 47.8 at. % Al; Al–Ag (1050°), $Q_{max.}$ = +1242 cal., 74.1 at. % Ag; Mg–Ag (1050°), $Q_{max.}$ = +3050 cal., 46.1 at. % Ag; Sb–Ag (1050°), $Q_{max.}$ = +1192 cal., 71.6 at. % Ag; Sb–Cu (1200°), $Q_{max.}$ = +903 cal., 57.4 at. % Cu; Al–Cu (1200°), $Q_{max.}$ = +4880 cal., 62.2 at. % Cu; Sn–Cu (1200°), $Q_{max.}$ = +1077 cal., 71.4 at. % Cu. Because the heat for Sn–Cu was pos. and a max. at the concn. Cu_3Sn, it was thought that this compd. should persist up to the liquidus. Eight systems having no intermetallic compds. up to the liquidus showed neg. heat effects: Bi–Sb (800°), $Q_{max.}$ = —309 cal., 48.6 at. % Sb; Sn–Al (800°), $Q_{max.}$ = —1630 cal., 59.8 at. % Al; Zn–Al (800°), $Q_{max.}$ = —1215 cal., 48.6 at. % Al; Bi–Ag (1050°), $Q_{max.}$ = —1078 cal., 59.8 at. % Ag; Pb–Ag (1050°), $Q_{max.}$ = —1680 cal., 60.5 at. % Ag; Pb–Cu (1200°), $Q_{max.}$ = —2030 cal., 52.3 at. % Cu; Bi–Cu (1200°), $Q_{max.}$ = —1650 cal., 56.4 at. % Cu; Ag–Cu (1200°), $Q_{max.}$ = —1105 cal., 50.3 at. % Cu. Three exceptions were found, of which 2, Pb–Sb (800°), $Q_{max.}$ = +107 cal., 45.3 at. % Sb, and Sn–Sb (800°), $Q_{max.}$ = +1182 cal., 55.7 at. % Sb, were attributed to the presence of Sb, which, like Bi (see *C. A.* **22**, 718), has abnormal phys. properties. In the other exception, Sn–Ag (1050°), $Q_{max.}$ = +1260 cal., 67.9 at. % Ag, the reliability of the equil. diagram is questioned. The systems Cu–Au and Ag–Au showed very small heat changes and are offered as examples of ideal solns.

Measuring p_H values. SOLOMON F. ACREE. Fr. 694,936, May 1, 1930. A stable buffer standard of H-ion concn. is composed of an acid alkali metal salt of a dibasic org. acid the anion and cation of which have equal ionic mobility, *e. g.* acid Na phthalate mixed with very pure water. An alkali metal carbonate and an indicator, the latter being preferably regulated so as to be isohydric with the acid Na phthalate, are also present.

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

W. ALBERT NOYES, JR.

Radioactivity and the thermal history of the earth. ARTHUR HOLMES. *Naturwissenschaften* **19**, 73–9(1931).—A review with numerous references on the cooling process of the earth. B. J. C. VAN DER HOEVEN

Interaction of free electrons and radiation according to Dirac's theory of electrons and quantum-electrodynamics. I. TAMM. *Z. Physik* **62**, 545–68(1930).—Math. The Klein-Nishina formula is deduced. Transitions between neg. energy levels are essential to the scattering formula. A simple method for calcn. of the wave function of a free electron is given. B. C. A.

Proper energy of an electron on the quantum theory of scattering. I. WALLER. *Z. Physik* **62**, 673–6(1930); cf. *C. A.* **25**, 23.—Math. The difficulty of an infinite proper energy of a free electron in an electromagnetic field is discussed with the use of Dirac's relativity and non-relativity dynamics. B. C. A.

Mechanics of photons. V. FOCK. *Compt. rend.* **190**, 1399–1401(1930).—A math. development is given of the mechanics of a photon by treatment of Maxwell's equations in a manner corresponding with the wave motion of a photon (light quantum). An equation for a single photon is deduced and extended to a number of photons by application of Dirac's method of "posterior" quantification. The reasoning may be applied to the deduction of Einstein's law of energy fluctuation and to the laws of the interaction of matter and light. B. C. A.

Undulatory theory of quantum phenomena. L. DÉCOMBE. *Compt. rend.* **190**, 1385–7(1930).—The author's theory (*C. A.* **24**, 1575), when applied to band spectra, indicates that the Deslandres spectral term (*C. A.* **24**, 3950) is attributable to ionic oscillations about the center of gravity of the mol. With the assumption of a const. H for the proton, analogous to the electronic quantum const. (h), it is shown that there is resonance between the 2 rotatory frequencies of the spinning proton and electron. B. C. A.

Application of group theory to the quantum dynamics of monatomic systems. CARL ECKART. *Rev. Modern Physics* **2**, 305–80(1930).—The math. principles of finite group theory are discussed with special reference to quantum dynamics. The general theory includes discussion of invariant manifolds, Schur's lemmas, perturbation theory, multiplication of groups and orthogonality relations. The applications are concerned with complex at. spectra and include the method of sums, selection principles, alterna-

tion rule of multiplets, the permutation group and the Pauli principle. The influence of external fields is considered for the Zeeman and Stark effects. Mol. spectra, valence and electron conduction are not discussed. G. M. MURPHY

Magnetic susceptibility of certain complex molybdenum compounds. PRIYADA RANJAN RÂY. *J. Indian Chem. Soc.* **7**, 741–3(1930).—The mass susceptibilities of 5 complex coördination compds. of quinquevalent Mo were measured at 29°. The results ranged from $\chi_m = 2.435 \times 10^{-6}$ for $(C_5H_6N)_2MoOCl_5$ to $\chi_m = 1.140 \times 10^{-6}$ for $(C_5H_5N)_2MoOBr_3$. The corresponding Weiss magneton nos. are 8.093 and 7.257, and in every case the nearest Bohr magneton no. is one. These results do not agree with Bose's rule for the magneton no. and a table of possible electron arrangements to account for the anomaly is given. It is also suggested that the magnetic behavior of Mo may be masked by that of the org. radical. W. W. STIFLER

The motion of ions and colloid particles in an electric field. H. H. PAINE. *South African J. Sci.* **27**, 11–22(1930).—An address, in which the analogy between ions and colloid particles, as concerns their elec. structure, is discussed from the standpoint of the Debye-Hückel theory. C. E. P. JEFFREYS

The presence of hydrogen ions among the positive thermions as usually obtained. III. Catalytic hydrogenation. OTTO SCHMIDT. *Z. physik. Chem.*, Abt. A, **152**, 269–83(1931).—Theoretically it appears impossible to form H^+ by thermal emission. S. finds exptl. proof of this and so all theories of hydrogenation as an ionic reaction in the gas phase are invalid. This does not preclude the possibility of such reactions in the metal phase. The app. is described and data are given. V. F. HARRINGTON

Measurements on the Langmuir dark space. A. GÜNTHERSCHULZE. *Z. Physik* **62**, 619–23(1930).—The Langmuir dark space which surrounds an electrode maintained at a neg. potential, with respect to a region in which a discharge is maintained, is due to the relative inefficiency of pos. ions in producing new ions on collision and is accompanied by a pos. space charge. The dimensions of this dark space can be calcd., provided certain conditions are fulfilled, by the simple form of the space charge equation. Expts have been carried out in H, He, Ne and A in which the above-mentioned conditions are approx. fulfilled; a fairly satisfactory agreement exists between the observed and calcd. dimensions of the dark space. B. C. A.

Wave length of x-rays. T. H. LABY AND R. BINGHAM. *Nature* **126**, 915–6(1930).—By means of a plane glass grating of 10,800 lines to the inch, a vacuum spectrograph and x-ray tube with graphite target in the same vacuum, it was found that the carbon K line could be photographed from the 18th neg. to the 13th pos. order. With very small dispersion, the carbon K line was compared with Cu L_α and L_l in their 2nd and 4th orders, the wave lengths 44.7 and 44.8 A. U. being obtained for the C line relative to 13.32 for the Cu L_α line. Al $K_{\alpha_1\alpha_2} = 8.315$ A. U. relative to Cu $K_{\alpha_1\alpha_2} = 1.5392$ A. U. C. E. P. JEFFREYS

Electron emission by collision of positive ions at low gas pressures. A. GÜNTHERSCHULZE. *Z. Physik* **62**, 600–6(1930).—The efficiency of pos. ions for the liberation of electrons has been examd. at a Cu surface acting as a subsidiary electrode adjacent to a low-voltage arc in A, Ne and He, the pressure ranges being 0.0017–0.0036, 0.0126–0.0156 and 0.019–0.026 mm., resp. The efficiency is of the same order in all these gases and increases from about 10 to 30% as the potential of the subsidiary electrode is increased sevenfold. B. C. A.

The emission of positive electricity from palladium. FR. GULBIS. *Acta Univ. Latviensis, Mat. un Dabas Zinatnu Fakult.* Serija I, Fasc. 1. Burtnica, (in English 51–66)(in Lettish 67–8)(1931).—G. investigates the pos. (thermionic) emission of Pd in order to det. the decay of emission with time, and the effect of occluded gases and dirty surfaces. The app. used consisted of a loop of pure Pd wire surrounded by a cylinder of Pt foil, electrically connected to an electrometer. The 2 electrodes were enclosed in a pyrex bulb attached to a vacuum pump and an auxiliary spark gap for testing the reduced pressure. The Pd electrode was removable for cleaning. The values detd. for the decay of emission with time were not found to agree with the equation $i - i_0 = Ae^{-kt}$, but they more nearly agreed with the expression $it = K$. Attempts to revive the Pd by admission of dry air or H_2 for several hrs. were unsuccessful, but contact with H_2SO_4, HCl, H_2O, EtOH, Et_2O, grease and dust particles gave various increases in the emission. Immersion of the Pd wire in toluene or xylene caused no increase in emission. The theory is advanced that the pos. emission of metals is due to some "active matter" which is widely distributed and which can be transferred from one body to another. The ions of the "active matter" are thought to be bound in the metal in such a way that a definite energy is required for their liberation. The process of emission is unknown but is maintained by itself and decays with time. Temp. is only a promoter of it. H. W. L.

Oxygen films on tungsten. I. A study of stability by means of electron emission in presence of cesium vapor. I. LANGMUIR AND D. S. VILLARS. *J. Am. Chem. Soc.* 53, 486–97(1931); cf. *C. A.* 19, 931.—W filaments in the presence of Cs vapor emit more electrons than the pure W filament. Up to 640°K. at which emission is many billion-fold that of pure W the Richardson equation, $i = AT^{\frac{1}{2}}\epsilon^{-b/T}$, is valid in the presence of Cs vapor. If O is admitted to activate the filament by forming a W–O–Cs surface the emission is greatly increased and the Richardson equation is valid to much higher temps. A theoretical discussion of results and a description of exptl. methods are given with suggestions for their application to the study of the loss of O from films on W and its detection in a gas. A. LLOYD TAYLOR

γ-Rays in the power field. ROBERT F. MEHL AND CHARLES S. BARRETT. *Power* 73, 340–2(1931).—The penetrative limit of γ-rays through steel is about twice that of x-rays. The expense of radiographs taken with γ-rays may be less than of those taken with x-rays since Ra capsules may be rented and are easily portable. D. B. DILL

An attempt to demonstrate the existence of short-range α-particles from radium C. G. H. HENDERSON AND J. L. NICKERSON. *Proc. Trans. Nova Scotian Inst. Sci.* 17, 256–8(1930).—An attempt was made to detect short-range particles from Ra C by the Wilson chamber method, but no group of particles of definite range could be detected above the general background. RACHEL BROWN

The rate of flow of heat of some radioactive minerals. A. DORABIALSKA. *Bull. intern. acad. Polonaise* 1930A, 42–9(in French).—See *C. A.* 24, 1280. J. W.

Application of an adiabatic microcalorimeter for measurements of rates of flow of heat of uranium, thorium and radioactive minerals. A. DORABIALSKA. *Bull. intern. acad Polonaise* 1929A, 487–96(in French).—See *C. A.* 24, 2042. J. W.

Photographic effects of γ-rays. J. S. ROGERS. *Proc. Phys. Soc. London* 43, Pt. I, 59–67(1931).—γ-Rays from Ra and Rn in equil. with their short-lived products were collimated between Pb blocks and allowed to fall on Agfa duplitized film. Besides the direct beams, rays filtered through lead screens, varying in thickness from 0.19 to 4.03 cm., were used. The densities of the traces on the films were measured with a Moll microphotometer. Results are given for the variations of photographic density both with time and with intensity of radiation. The shape of the characteristic curves was found to be independent of filtering. Similar results were obtained for the Hurter–Driffield curves, except when no lead filter was used. The absorption coeff. of Pb was found to be 0.533 cm.$^{-1}$ for thicknesses from 1 to 7 cm. W. W. STIFLER

Ionium in dispersed masses of Tyuya-Muyun. Description of the method of preparation of a solution for its determination. I. D. KURBATOV, N. A. KARZHAVINA AND N. A. SAMOILO. *Compt. rend. acad. sci. U. R. S. S.* 1930A, 69–74.—In certain ores of Tyuya-Muyun, Ra is shown to be present in excess of the amt. in radioactive equil. with U. It is assumed that this is due to the presence and transformation of Io. As there is no direct method for detn. of Io an indirect method was devised to solve the problem whether Io is in excess of the equil. ratio of Io:U. The sample was fused with Na_2CO_3 and a Ba salt. Ra and Ba were sepd. as sulfates. The initial amt. of Ra and that resulting from transformation of Io were detd. with a Wulf electrometer. The results confirmed the assumption. Still another mineral deposit of Io and Ra probably exists in Tyuya–Muyun. J. G. TOLPIN

Proportions of active elements in dispersed masses of Tyuya-Muyun. I. D. KURBATOV. *Compt. rend. acad. sci. U. R. S. S.* 1930A, 452–8(1930).—Ra ore in Tyuya–Muyun consists of (*a*) active minerals contg. Ra, (*b*) minerals that contain no Ra but exert no influence upon the soly. of *a* in acids and (*c*) minerals contg. no Ra and lowering the soly. of Ra-contg minerals. Only minerals of class *a* are discussed here. Most important of them is tyuya–muyunite, $CaO.2UO_3.V_2O_5.xH_2O$, which is easily sol. in dil. acids. Another Ra-bearing mineral with entirely different chem. properties is brass-yellow radiobarite. From disturbed radioactive equil. it was concluded that other Ra-bearing minerals could be found in Tyuya–Muyun fields. For exptl. work active dispersed masses were chosen. Detn. of U and Ra showed an excess of Ra over the equil. amt. from 0.25×10^{-7} to 0.50×10^{-7} for each g. of U. The excess is explained as being due to sepn. of Ra and Io from the ore in quantities in excess of the equil. amt. or to disturbance of equil. on account of migration of the active element with the sepn. of a new mineral contg. Ra and Io formerly present in U mineral. In the second case the new mineral should be less sol. than tyuya–muyunite. Exptl. evidence tends to show the opposite. At least 3 minerals in which Ra is being concd. are present in Tyuya–Muyun; (1) tyuya–muyunite where Ra is stored (U ⟶ Io ⟶ Ra); (2) radiobarite (Io ⟶ Ra); (3) dispersed Fe_2O_3 in primary ores (Io ⟶ Ra). J. G. TOLPIN

Optics of x-ray reflection from crystals. V. Wide-angle diagrams. H. SEEMANN. *Ann. Physik* [5], 7, 633–49(1930); cf. *C. A.* 25, 870. C. E. P. JEFFREYS

Studies in x-ray diffraction. I. The structure of amorphous carbon. P. KRISHNAMURTI. *Indian J. Physics* 5, 473–86(1930).—X-ray powder diffraction patterns were measured for amorphous carbon prepd. from benzene, sugar, C_2Cl_6 and CCl_4, for active charcoal and for Acheson graphite. A strong scattering extending to an angle of 7° was observed for amorphous C which indicates that the C atoms are joined together in clusters of about 60 atoms of C per unit. **II. Some colloidal solutions and liquid mixtures.** *Ibid* 489–98.—Aq. solns. of starch, tannic acid and gum arabic show a strong scattering at small angles to the primary beams due to dissolved mols. or micelles. The mol. wts. calcd. from the extent of the corona were 6200, 3134 and 2810, resp. The small angle scattering from AcOH disappears immediately on diln. indicating a breaking up of mol. assocn. Mesitylene-cyclohexane, and ethyl phthalate-benzene systems were also investigated. **III. Aromatic hydrocarbons in the solid and liquid states.** *Ibid* 543–58.—Acenaphthene, naphthalene, fluorene and phenanthrene show 2 rings in the liquid state while biphenyl, bibenzyl and stilbene show only one. An explanation for this is given based on the assumption of impedance to free rotation or vibration for compds. having *o*- and *m*-substitution in the aromatic nucleus. The relation of the liquid diffraction patterns to crystal structure data is discussed. MALCOLM DOLE

X-ray diffraction in heated liquids and in solutions. V. I. VAIDYANATHAN. *Indian J. Physics* 5, 501–24(1930).—This work was done to test the applicability of the Einstein-Smoluchowski theory of optical scattering to small angles of scattering with x-rays. Since, according to this theory, the ratio of the intensity of the scattered to the incident beam must increase at high temps., the x-ray scattering of a no. of liquids was examd. at high temps. With benzene the ratio is greater than the ratio of scattering in the optical region. The abs. values of the ratio for water and benzene at room temp. were calcd. theoretically and shown to agree well with the observed values. The origin of the inner and outer rings is considered. Since the inner halo intensity did not diminish with rise of temp. with assocd. liquids like phenol, the conclusion is that the inner ring origin is not due to assocn. The theory of scattering by dissolved mols. is also discussed from a math. standpoint. MALCOLM DOLE

Part-absorption phenomena of x-rays. R. C. MAJUMDAR. *Nature* 127, 92 (1931).—Partly absorbed lines were observed with C, N and Al as the absorbing substances and the incident radiations from Fe $K\alpha_{1,2}$, Fe $K\beta_1$ and Ni $K\alpha_{1,2}$. Cf. Ray, *C. A.* 24, 5608. H. F. JOHNSTONE

Influence of the form and polarity of molecules on the Röntgen spectrum of liquids. III. The appearance of two amorphous rings in substances whose molecules are probably disk-shaped. J. R. KATZ AND J. SELMAN. *Z. Physik* 66, 834–57(1930); cf. *C. A.* 22, 2881.—The Rontgen spectra of many fluid org. compds. have been observed and are found to consist of 2 "amorphous" rings sepd. by a zone of more or less diffuse light. Measurement of the rings gives data from which the structure of the mol. groups is inferred. The mols. are regarded as disks arranged in parallel layers very similar to a stack of coins, the stacks forming a space grating. This arrangement is disturbed by thermal excitation whereby the axes of the groups assume a random distribution and individual mols. may wander from one group to another. This is betrayed by a loss in distinctness of the rings in the Röntgen diagram. C. C. KIESS

The intensity relations in the spectrum of a mixture of alkalies and the possibility of a quantitative spectrum analysis of these elements. HORST LUCAS. *Z. anorg. allgem. Chem.* 195, 321–37(1931); cf. *C. A.* 24, 5663.—The arc and spark spectra of salts of Na and K mixed in various proportions were photographed together with a source of white light of known intensity distribution to study the possibility of making quant. spectrochem. analyses. It was found that the relative intensities of the lines, as detd. from microphotometer measurements, depended on the region of the arc under investigation. In the middle zone of the arc where the temp. and elec. field are lowest the spectrum of K is emitted with greater strength than that of Na. Detns. of the relative concns. of Na and K from the line intensities were made with an accuracy of approx. 20%. As a by-product of the investigation it was found that the relative intensities of the principal and subordinate series are 1:100. C. C. KIESS

The dispersion of internal energy between the quartet and triplet terms $3s$P, $3p$P, and $3p$D of the spectra of carbon, nitrogen, oxygen and fluorine in different stages of ionization. J. GILLES. *Compt. rend.* 192, 350–2(1931).—From a study of the sepns. shown by the triplet and quartet *P* and *D* terms of C, N, O and F, coming from the electron configurations $1s^22s^22p3p$ and $1s^22s^22p^23p$, resp., it was found that (1) in passing from the 4th to the 6th column of the periodic table the triplet sepns. are very

nearly 80 × 2 and 80 × 4 wave no. units; (2) from the 5th to the 7th columns the quartet sepns. are very nearly 80 × 3 and 80 × 5 units. C. C. KIESS

Investigations of the anomalous dispersion of excited gases. V. Negative dispersion in excited neon. H. KOPFERMANN AND R. LADENBURG. *Z. Physik* **65**, 167–88(1930); cf. *C. A.* **22**, 2514.—The neg. dispersions of the Ne lines resulting from the $s_k - p_k$ combinations were measured by the method previously described (*C. A.* **22**, 4364). With increase in strength of the current in the discharge tube the anomalous dispersions of all the lines terminating in the s_k state increase in the same manner; but when the c. d. reaches 0.1 amp./sq. cm. the dispersions begin to decrease by amts. different for each line, depending on the atom density of each of the p_k states. The no. of atoms in each of the p_k states appears to reach a satn. value for a max. current of 0.7 amp., apparently because of the equil. between the atom densities of the various p_k states and the exciting and neutralizing electrons. The sp. temp. for the s and p states derived from the measurements for max. current is approx. 23,000°. **VI. Control experiments for demonstrating negative dispersion: absorption, anomalous dispersion, intensity distribution and intensity of different neon lines.** R. LADENBURG AND S. LEVY. *Ibid* 189–206.—Exptl. tests of the above interpretation of the anomalous dispersion of Ne lines is afforded by: (1) the anomalous dispersion and absorption shown by lines resulting from combination of a p_k state with a higher state; (2) the increase in intensity of the $s_i - p_k$ lines with increase in strength of the exciting current. Measurements of the anomalous dispersion and absorptions of the line at 7059 A. U. ($p_{10} - s_1''$) show that they increase markedly when the crit. current strength is reached; and investigations of the intensity distribution within the red line at 6304 A. U. by means of the Fabry–Perot interferometer show that it is caused solely by a Doppler effect. A formula is derived for the intensity of a spectrum line affected by absorption within a finite gaseous ayer. C. C. KIESS

Two remarks on the dispersion of mercury vapor. R. LADENBURG AND G. WOLFSOHN. *Z. Physik* **65**, 207–8(1930); cf. *C. A.* **24**, 5631.—(1) The new dispersion measurements in Hg vapor give a value of 1.14×10^{-7} sec. for the life of the $^1P_1$ state. (2) The frequency corresponding to the limit at 1190 A. U. of the principal series of Hg has assocd. with it a large f-value (2.59). This is attributed to the first simultaneous jump of both valence electrons. C. C. KIESS

The variations in intensity distribution in a resonance spectrum. LUDWIK NATANSON. *Z. Physik* **65**, 75–83(1930); cf. *C. A.* **24**, 5226.—The resonance spectra of Te and Se, excited by light from a Hg lamp, were observed at different pressures. The spectrograms, exposed also to the light of a W-filament lamp. were microphotometered to study the changes in intensity in the members of the resonance spectrum caused by the change in pressure. For Te intensity changes were noted which could not be attributed to absorption of the resonance rays by the vapor itself. For Se, in which the doublets of the resonance series were resolved by the spectrograph employed, the long wave length component of each doublet was strengthened relative to the short wave component with increase in pressure, the effect of absorption being eliminated. C. C. K.

Quantized rotation of the potassium atom. R. G. LOYARTE AND R. GRINFELD. *Univ. Nacl. La Plata, Estudio Cienc.*, No. 89, 103–8(1929); *Science Abstracts* **33A**, 645; cf. *C. A.* **24**, 2669.—Williamson has published curves which show the stimulation of K atoms by electron shocks. These curves show that it is probable that there is a quantized rotation of these atoms. The crit. potential, which corresponds to the leap from level $n = 0$ to level $n = 1$, must be 3.39 v., which corresponds to a $\Delta\nu = 27{,}441$ cm.$^{-1}$. On spectroscopic testing, 23 lines of the arc and spark spectra of K are found, obtainable by combination of a rotation-quantum leap with the electron leaps. Since the value $\Delta\nu = 27{,}441$ cm.$^{-1}$ is very large, it is not possible to find lines for which to subtract the rotation-quantum leaps from those of the electrons, for such lines would be in the deep infrared, where measurements have not been made. The no. of combination lines within the observed region is, therefore, small. G. G.

Anomalous Zeeman effect. P. DRUMAUX. *Bull. assoc. ing. élec. électrotech. Montefiore* **7**, 101–8, 142–56, 164–72(1929); *Science Abstracts* **33A**, 678.—This paper, in 3 serial portions, gives a summary of the theory of the anomalous Zeeman effect. The 1st portion deals with the classical theory, the 2nd with the classical quantum theory and the description of the effect in different multiplets and the final portion gives the quantum-mechanics treatment, with the use of wave mechanics and the matrix mechanics of Heisenberg and Dirac. G. G.

Elementary theory of the Zeeman effect. J. ZAHRADNÍČEK. *Z. Physik* **62**, 694–5(1930).—The Lorentz equations for the motion of a bound electron in a magnetic

field are best solved by the usual transformation of 2 real equations into one imaginary equation. B. C. A.

The Zeeman effect of quadripole lines. E. SEGRÈ. *Z. Physik* **66**, 827–9(1930).—The narrow doublet of K at 4642.17 and 4641.58 A. U. representing the transition $^2S - {}^2D$ results from quadripole radiation. The Zeeman effects of these lines have been observed in a field of 12,700 gausses and confirm not only the theory of Rubinowicz for the Zeeman effect of quadripole radiation but also the character of these lines as forbidden $S - D$ combinations. C. C. KIESS

The Stark effect of some helium lines in the visible part of the spectrum. KARL SJÖGREN. *Z. Physik* **66**, 377–88(1930).—The canal ray method of Stark was used to observe the displacements of visible He lines produced by elec. fields ranging from 175 to 550 kv./cm. Details of the measurements are given for the lines $2S - 3P$, $2S - 3D$, $2P - 4S$, $2P - 4D$, $2P - 4F$, $2P - 4B$, $2p - 4s$, $2p - 4d$, $2p - 4f$ and $2p - 4p$. C. C. KIESS

Lithium-like spectra of carbon, nitrogen and oxygen, C IV, N V and O VI. B. EDLÉN AND A. ERICSON. *Z. Physik* **64**, 64–74(1930).—The spectra of C, N and O have been examd. in the extreme ultra-violet, the vacuum spark method being used. The series of Li-like doublets was obtained. For the fundamental term $2^2S_{0.5}$, for the different elements, the following values were obtained: C IV, 520, 220; N V, 789, 591; O VI 1,114, 206. These correspond with ionization potentials of 64.19, 97.428 and 137.482 v., resp. The term values for the complete series for Li I, Be II, B III, C IV, N V and O VI are compared. B. C. A.

C IV lines in the visible and near ultra-violet regions of the spectrum. The term system of C IV. BENGT EDLÉN AND JOHN STENMAN. *Z. Physik* **66**, 328–38(1930).—With the terms of C IV previously described (preceding abstract) the lines which should appear in the near ultra-violet and visible regions of the spectrum have been calcd. These lines and others belonging to C IV have actually been observed in the spectrum emitted by a condensed spark discharge between graphite electrodes in vacuum. These new wave length observations together with those in the extreme ultra-violet have permitted a redetn. of all the terms up to those with principal quantum no. 6. The ^2P terms follow Landé's formula for the doublet sepns. very closely, giving a value 1.82 for the screening const. σ. C IV is now the best representative of a Li-like spectrum. C. C. KIESS

The nuclear moments of Li^6 and Li^7. HERMANN SCHÜLER. *Z. Physik* **66**, 431–5 (1930); cf. *C. A.* **25**, 249.—With a Perot–Fabry etalon and a Schüler lamp, the hyperfine structure of the Li-II triplets, $2^2P_{0,1,2} - 2^2S_1$ at 5485 A. U., was photographed. Several discrepancies in the earlier measurements have been removed. The results do not agree with the calcd. nuclear moments, $i = {}^1/_2$ or ${}^3/_2$ but the latter is slightly favored. No splitting of the lines for Li^6 was detected. In case it exists, it cannot be more than ${}^1/_8$ as great as that for Li^7. G. M. MURPHY

The para-ortho splitting and the mean value of the *S*-terms of helium for higher quantum numbers. EGIL A. HYLLERAAS. *Z. Physik* **66**, 453–70(1930); cf. *C. A.* **25**, 1156.—Math. By a perturbation method, the term values for the *S*-states of para- and ortho-He are calcd. for higher quantum nos. A similar calcn. is made including the influence of the polarization of the atom core. The results are $E(n,0) = -Rh/(n - a)^2$, where $a = 0.176 \pm 0.054$, 0.22 ± 0.07, 0.219 ± 0.079 for calcn. without and with polarization effect and exptl., resp. G. M. MURPHY

The calculation of the spectra of ions. ENRICO FERMI. *Mem. accad. Italia, Classe sci. fis. mat. nat.* **1**, No. 2, 10 pp.(1930).—F. first presents his general method of calcg. the statistical distribution of the electrons in an ion. The electrons surrounding the nucleus are treated as a cloud of electronic gas, the d. of which is detd. statistically as a function of the distance from the nucleus. Next is given the calcn. of the elec. potential in the interior of an ion as a function of the distance from the nucleus. This makes possible the numerical calcn. of the energy levels, which procedure is exemplified by the calcg. of the *S*-terms, or rather their Rydberg corrections, of the spectra of triply ionized atoms. Good agreement between calcd. and observed values is shown. R. H. LOMBARD

The magnetic moments of atomic nuclei. ENRICO FERMI. *Mem. accad. Italia, Classe sci. fis. mat. nat.* **1**, No. 1, 12 pp.(1930).—The hyperfine structure of spectra is due to the interaction between the motion of the electrons of the atom and the intrinsic magnetic moment of the nucleus. Methods are derived theoretically for calcg. this hyperfine structure of spectral lines. The magnetic moments of the nuclei of Na, Rb and Cs are deduced by applying these theoretical results to the experimentally detd. hyperfine structure of the spectra of these elements. R. H. LOMBARD

Nuclear spin and the third law of thermodynamics. The entropy of iodine. W. F. GIAUQUE. *J. Am. Chem. Soc.* **53**, 507–14(1931); cf. *C. A.* **25**, 867.—The value of $S_{298.1} = 27.9$ calorie/degree per mole of solid I obtained by extrapolation of existing data represents the abs. entropy less the nuclear spin entropy. For gaseous I the combined translational, rotational and vibrational entropies consists of the abs. entropy less the nuclear spin entropy and has a value as obtained from band spectra, $S_{298.1} = 62.29$ cal./degree/mole. The high temp. entropy effects due to nuclear spin in I are found to persist below 10°K., which is not the case for H. The *vapor pressure of solid I* is given by the equation, $\log_{10}P(\text{atm.}) = -(3512.3/T) - 2.013\log_{10}T + 13.374$.
A. LLOYD TAYLOR

Nuclear spin of nitrogen. W. R. VAN WIJK. *Arch. neerland. sci. IIIA*, **13**, 29–57 (1930).—In certain band spectra of mols in which the atoms are identical, alternate lines are very weak or even missing. This is ascribed to the symmetry of the mol. and to resonance in the at. nuclei. The theory of this method of investigating the nucleus, by photometric measurements of the intensities of the lines in the band spectrum, is outlined, with special reference to the N_2 mol. Exptl. details are given for work carried out on spectra emitted by the N_2^+ and the neutral N_2 mols. The ratio of the alternating intensities of the neg. bands at 3914, 3884, 4278 and 4237 A. U. was found to be 2:1. A Maxwell-Boltzmann distribution among the rotational levels was found. The ratio for the nuclear spin was confirmed by other measurements, including work on the resonance line of Th at 3776 A. U.
W. W. STIFLER

The experimental assignment of the H_2 bands to the singlet and triplet systems. W. FINKELNBURG. *Z. Physik* **66**, 345–9(1930).—A spectrogram of H_2 (obtained by Gehrcke and Lau) excited by streams of electrons of various velocities shows the same effect as that described for the singlet and triplet lines of Hg by Schaffernicht (*C. A.* **24**, 5621). The lines which extend entirely across the spectrogram with undiminished intensity as the excitation energy increases are those belonging to the A, B and analogous bands of the singlet system. Those lines extending only part way across the spectrogram, fading out with increasing energy of the cathode rays, belong to the α,β,γ and δ bands of the triplet system.
C. C. KIESS

Optical dissociation of diatomic molecules in gases and vapors. I. II. III. G. H. VISSER. *Chem. Weekblad* **27**, 237–41, 380–4, 390–3(1930). A survey of recent work.
B. C. A.

Analysis of the S_2 spectrum. R. ROMPE. *Z. Physik* **65**, 404–29(1930).—This analysis of the S_2 spectrum includes: (1) the bands classified by Rosen (*C. A.* **22**, 2717; **23**, 564) which are shown to represent a $^1\Sigma - {}^1\Pi$ transition; (2) the ultra-violet bands described by Gilles (*C. A.* **23**, 4406) which result from the term combinations $^1\Sigma - {}^3\Sigma$ (or $^1\Sigma$) and $^1\Sigma - {}^3\Pi$; (3) the resonance bands excited by the ultra-violet rays of Hg. Five resonance series have been observed. These have been arranged into band schemes for which the corresponding anti-Stokes members have also been observed. The intensity distribution within the resonance series resembles that noted by Rosen for the fluorescence spectrum and deviates markedly from that required by Condon's theory. The effect of the addn. of a foreign gas, N_2 or He, to the S_2 vapor is to bring out more or less completely the band systems assocd. with the resonance series.
C. C. KIESS

The emission bands of sulfur. R. K. ASUNDI. *Nature* **127**, 93–4(1931).—Spectrograms of the emission bands of S were obtained from discharge tubes contg. S vapor in the presence of high-pressure A. New bands toward the red indicate that A helps in some way to prevent the predissocn. of the S mols. A few new bands degraded toward the shorter wave lengths were also obtained in the extreme ultra-violet beginning from about λ2100 A. U.
H. F. JOHNSTONE

Raman spectra of some triatomic molecules. S. BHAGAVANTAM. *Nature* **126**, 995 (1930).—Photographs of the Raman spectrum of SO_2 gas show a line with a wave no. shift of 1154, which differs somewhat from the strong line having the shift 1146 which was previously found in the Raman spectrum of liquid SO_2. The 2 fainter lines found in the spectrum of the liquid do not appear in that of the gas. Photographs of the spectrum of liquid HCN show a triplet with shifts of 2076, 2097.2 and 2122, the middle component being much stronger than the others. The results of Krishnamurti on CS_2 were confirmed and 3 new, very feeble bands at 4438, 4605 and 4680 A. U. were found in the spectrum of CS_2 excited by the Hg line at 4358.3 A. U.
W. W. STIFLER

Raman effect and molecular structure. III. The basic frequencies of molecules of the type XY_4. Mixed halides. B. TRUMPY. *Z. Physik* **66**, 790–806(1930); cf. *C. A.* **25**, 250.—The Raman spectra of CCl_4, $SiCl_4$, $TiCl_4$, $SnCl_4$, $SnBr_4$ and of mixts. of $SnCl_4$ and $SnBr_4$ in the ratios 1:1, 3:1 and 1:3, were observed. The measurements show that the tetrachlorides and also the tetrabromide all exhibit 4 basic frequencies, those of

$SnBr_4$ being displaced to longer wave lengths compared with those of $SnCl_4$. These observed frequencies are in good agreement with those calcd. from a theoretical consideration of a mol. having its outer atoms at the vertices of a tetrahedron. Two of the frequencies represent active oscillations and 2 inactive oscillations of the mol. The infra-red absorption spectra of these compds., so far as known, correspond to the active oscillations and to combinations of them. The Raman spectra of the mixts. show new lines in addn. to those due to the constituent mols. The lines of the original mols. are weak compared to those of the new mols., which are probably of the form $SnCl_2Br_2$, $SnClBr_3$ and $SnCl_3Br$. C. C. KIESS

Apparatus for the demonstration of the Raman effect in liquids. N. B. REYNOLDS AND F. BENFORD. *Rev. Sci. Instruments* 1, 413–6(1930).—A hot-cathode He lamp (of cylindrical shape) is used in conjunction with a Ni oxide glass filter (cf. Wood, *C. A.* 23, 5419). The lamp is surrounded by a reflector of elliptical cross section, the cross section of the lamp being concentric with one of the foci of the ellipse. Concentric with the other focus is placed the tube contg. the liquid to be examd. A hot-cathode Hg lamp has been similarly used. B. C. A.

The Raman effect and the polymerization of water at various temperatures. O. SPECCHIA. *Nuovo cimento* [N. S.], VII, 10, 388–91(1930).—At room temp. the Raman spectrum of water excited by means of a Hg arc over the range 4108 to 5790 A. U. gives 3 bands of greatest intensity at 4176, 4693 and 5158 A. U., and 2 much weaker bands at 4258 and 4480 A. U. The bands at 4176 and 4693 A. U. are composed of 3 components each. The effect of increase of temp. in modifying the band at 4176 A. U. was particularly studied. Measurements were made between 17° and 91°. A marked diminution of intensity of the 3 components of this band was noted with increasing temp., as well as a displacement toward greater wave length. L. T. FAIRHALL

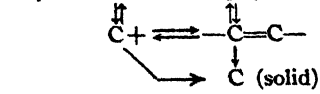
The photochemical union of hydrogen and chlorine. I. The effect of light intensity. ARTHUR J. ALLMAND AND EDWARD BEESLEY. *J. Chem. Soc.* 1930, 2693–708.—An extensive study to det. the relation between the reaction velocity and the intensity of light in the photochem. combination of H_2 and Cl_2. Thus, 405 mμ and 436 mμ monochromatic light over measured intensity ratios of about 180:1 and 440:1 resp., plane-polarized complex light over a measured intensity ratio of 4:1, and intermittent monochromatic light of wave lengths 313 + 303 mμ, 365 mμ, 405 mμ and 436 mμ are used. The light intensities are measured with a thermopile. They are varied in the expts. with the 405 mμ and the 436 mμ monochromatic light by 4 wedges of neutral tint and continuously varying density, with the polarized light by crossed Nicol prisms, and in the expts. using the intermittent monochromatic light by a rotating disk with 2 adjustable open sectors in opposite quadrants. The results show that the reaction velocity is proportional to the intensity of the incident light. The results of Baly and Barker (*C. A.* 24, 2385) are explained. J. BALOZIAN

The photochemical union of hydrogen and chlorine. II. The effect of wave length. Measurements with filtered light. ARTHUR J. ALLMAND AND EDWARD BEESLEY. *J. Chem. Soc.* 1930, 2709–21.—The dependency of the quantum efficiency (γ) on the wave length (260–546 mμ), the relative temp. coeffs. for the lines 436 mμ, 405 mμ, 365 mμ and 313 + 303 mμ (comparative velocity measurements being made at 19.7° and 25.0°), and the simultaneous effect of 2 monochromatic rays are investigated in the photochem. reaction between H and Cl. The app. and methods are similar to those used in expts. of the preceding abstract, extra light filters (260 mμ and 546 mμ) being also used. With decreasing wave length, γ at first increases to a max. and then decreases rapidly in the ultra-violet. The expts. show that between 313 mμ–436 mμ the temp. coeff. of γ increases with increasing wave length. In every case the simultaneous effect of 2 monochromatic rays is equal to the sum of their sep. effects. The threshold wave length for this reaction is found to be 546 mμ. J. BALOZIAN

The photo-reaction of hydrogen and iodine monochloride. D. P. MELLOR AND T. IREDALE. *Nature* 127, 93(1931); cf. Rollefson and Lindquist, *C. A.* 24, 4224.—H and ICl react rapidly in strong light if the H pressure is large compared with the pressure of ICl. This indicates that conditions favor the greater probability of the reaction, $H_2 + Cl \longrightarrow HCl + H$, and that excited Cl atoms may not be necessary for it to take place. In thin glass bulbs the reaction between H and ICl is very slow in artificial light, more rapid in diffuse daylight, and very rapid in direct sunlight, I_2 and HCl being the main products. H. F. JOHNSTONE

Photo-reaction between hydrogen and iodine monochloride. G. K. ROLLEFSON AND F. E. LINDQUIST. *J. Am. Chem. Soc.* 53, 1184–5(1931).—R. and L. point out that the results of Mellor and Iredale (preceding abstract) are not inconsistent with their

previous conclusions (*C. A.* **24**, 4224), since their exptl. conditions were considerably different. C. J. WEST



Photochemical interaction of ethylene and ammonia. HUGH S. TAYLOR AND HARRY J. EMELEUS. *J. Am. Chem. Soc.* **53**, 562–74(1931).—The photochem. decompn. of NH_3 in the presence of C_2H_4 and C_2H_4-H_2 mixts. induces a polymerization of C_2H_4 at room temp. to a liquid product. A formation of satd. hydrocarbons is subordinate to this process. The velocity of the reaction is independent of the C_2H_4 pressure over a wide range, and of NH_3 pressure when absorption is complete. Conclusions are reached as to the efficiency of methods for producing satd. hydrocarbons from C_2H_4 and at. H. C. E. P. JEFFREYS

Photochemical decomposition of hydrogen peroxide in aqeuous solution in presence of sodium nitroprusside. I. M. QURESHI. *J. Phys. Chem.* **35**, 656–8(1931).—An aq. soln. of H_2O_2 to which a few drops of Na nitroprusside soln. are added is sensitive to the visible light, the decompn. of the H_2O_2 continuing after the illumination ceases. It is probable that the illumination produces some colloidal Prussian blue which acts as a catalyst for the dark reaction. The course of the reaction was not followed quantitatively but this will be done later. HARRY B. WEISER

The transfer of energy between atoms at collision. OSCAR KNEFLER RICE. *Proc. Nat. Acad. Sci.* **17**, 34–9(1931).—Kallmann and London have considered the question of energy exchange between atoms and mols. at distances greater than those comparable with the at. or mol. radii. They neglected the relative translational energy of colliding atoms or mols. A modification of Born's method for solving collision problems is outlined which takes into account the mutual kinetic energy of the particles and meets the objection of K. and L. (*C. A.* **24**, 4696) to Frenkel's suggestion (*C. A.* **24**, 2052). V. F. HARRINGTON

The separation of two types of iodine molecule and the photochemical reaction of gaseous iodine with hexene. R. M. BADGER AND J. W. URMSTON. *Proc. Nat. Acad. Sci.* **16**, 808–11(1930).—Since one type of I mol. absorbs the Hg line 5461 and the other does not, an attempt at sepn. has been made by causing the activated type to react with hexene vapor. Indications, which are not conclusive, point to a partial sepn. J. B. AUSTIN

The mechanism of the action of electrical discharge upon methane. KURT PETERS AND O. H. WAGNER. *Brennstoff-Chem.* **12**, 67–8(1931); cf. *C. A.* **23**, 3861, 4326; **24**, 2955, 5715; **25**, 399, 645.—Spectrum analysis of the arc in the discharge tube before the color change observed upon increasing the elec. charge shows the bands of the —CH, N and —CN groups. This is taken to show the progression in radicals from $CH_3 \longrightarrow CH_2 \longrightarrow CH$. Polymerized satd. hydrocarbons are thus formed at low pressures and low charges while C_2H_4 and C_2H_2 are formed at high pressures. Following the change from pale blue to yellow, bands of the Balmer series, the Swann spectrum with exception of group I, and the —C≡C— and C+ groups were observed. Solid hydrocarbons result from the reaction of —C≡C— groups with reactive H. The mechanism is indicated as

The relation between elec. consumption, % in the final gas and the charge is shown graphically for C_2H_2 and C_2H_4. F. W. JUNG

The ammonia discharge tube. G. I. LAVIN AND J. R. BATES. *Proc. Nat. Acad. Sci.* **16**, 804–8(1930); cf. *C. A.* **24**, 3441.—The active gas reacts with ethylene to give cyanides and with O to give nitrides. Solid surfaces show sp. action. Cu and Fe_2O_3 extinguish the glow immediately. Sn, Ni, Fe, Pt, show an induction period. Mo and W produce little effect. J. B. AUSTIN

Disadvantages of the quartz lamp in fluorescence analysis. J. PLOTNIKOV. *Chem.-Ztg.* **54**, 582(1930).—The low light intensity, fragile nature, and monochromatic emission are mentioned; only those substances fluoresce under the lamp which can absorb radiation of wave length 366 mμ. B. C. A.

Transmission changes in ultra-violet glasses during high-temperature exposure to light. C. C. NITCHIE AND F. C. SCHMUTZ. *Science* **71**, 590(1930).—When kept in contact with the hot tube of the Hg-arc lamp (about 450°), certain glasses showed a marked increase in short-wave transmission. B. C. A.

The absorption of ultra-violet rays by liquids transparent to light. J. CLUZET

AND T. KOFMAN. *Compt. rend. soc. biol.* **103**, 783–5(1930).—A Cd photoelec. cell was used to measure the ultra-violet light (3000–2300 A. U.) absorbed by several liquids transparent to visible light. B. C. BRUNSTETTER

Quantitative investigations on the absorption spectra of organic dyes. J. AUŠKĀPS. *Acta Univ. Latviensis Kim. Fakultat. Serija* **1** (in German) 362–8(in Lettish) 279–361.—Absorption spectra of 79 org. dyes were measured with a Koenig-Martens spectrophotometer between 7200 and 4100 A. U. Values of the mol. absorption const. are given for each. The advantages of the quant. method are discussed. The Lambert-Beer law is valid for weak dye solns. in presence of small amt. of colorless inorg. compds. The results are discussed with regard to the relation between spectra and structure of the dye. The advantages of the color-triangle are also discussed. G. M. MURPHY

Effect of impurities on the phosphorescence of calcium sulfide. D. N. GOYLE AND N. SINGH. *J. chim. phys.* **27**, 433–51(1930).—The effect of adding up to 0.1% of eosin, fluorescein, quinine hydrochloride, methyl blue, $PbCl_2$, $Pb(NO_3)_2$, $CuCl_2$, $CuSO_4$, $Cd(NO_3)_2$, $CdSO_4$, $Ba(NO_3)_2$, $BaCl_2$, $Sr(NO_3)_2$ and $SrCl_2$ to CaS on the phosphorescence of the CaS was measured. The first 6 named gave a max. effect in concns. of about 0.003%, the highest value being obtained with quinine hydrochloride. Addns. of the other mineral salts gave minima in small concns., followed by maxima which were usually lower than the initial value. The intensity of the radiation decreased with age. The luminosity of CaS is explained by the equations: (1) $2CaS + 2H_2O \rightleftharpoons Ca(SH)_2 + Ca(OH)_2$; (2) $CO_2 + Ca(OH)_2 \longrightarrow CaCO_3 + H_2O$; (3) $H_2O + CO_2 + Ca(SH)_2 \longrightarrow CaCO_3 + 2H_2S$. H_2S was detected by odor and by test with lead acetate. GERALD M. PETTY

Thermoluminescence in glasses which contain two activators. BYRON E. COHN AND WM. D. HARKINS. *J. Am. Chem. Soc.* **52**, 5146–54(1930).—The thermoluminescence of a zinc borate glass, caused by Ce and Mg, alone and mixed in concns. up to 1% of each element, was measured from 2600 to 3350 A. U. The effect of mixts. was not additive. Intensity measurements of the thermoluminescence indicate that the energy for thermoluminescence is drawn from near the edge of the absorption bands. Relative thermoluminescent intensity varies with the source of excitation. The data are presented graphically. GERALD M. PETTY

Scattering of light by dielectrics of small particle size. G. F. A. STUTZ. *J. Franklin Inst.* **210**, 67–85(1930). The diffusion of light by a dielec. material, Zn oxide, was investigated in the range of particle sizes where, with increasing particle size, Rayleigh scattering rapidly diminishes and reflection and refraction effects increase in importance. The turbidity max. for Zn oxide dispersed in water, detd. for 3 wave lengths of light, occurs at 0.25μ for the wave length 5500 A. U. and at smaller particle sizes for shorter wave lengths; the particle size of max. turbidity was found to be proportional to the wave length of the light in the range 4800–6300 A. U. An app. for detg. the angular distribution of the light scattered by a suspension of fine particles is described. The total observed intensity has not the same distribution as calcd. by Blumer (cf. *Z. Physik* **38**, 304(1926)); the observed depolarization is in fair agreement with theory (cf. Lange, *C. A.* **22**, 2503–4). B. C. A.

The acceleration produced by light of the flocculation of colloidal solutions in fluorescent media. AUGUSTIN BOUTARIC AND JEAN BOUCHARD. *Compt. rend.* **192**, 95–7(1931).—The effect of visible and of ultra-violet light on the rate of flocculation of As_2S_3 and other sols by electrolytes in presence of fluorescein, eosin and erythrosin was studied. In all cases illumination decreased the time required for flocculation, the effect being greater in ultra-violet than in visible light freed from infra-red. K_2SO_4 and H_2SO_4, which inhibit the fluorescence of the dyes, also suppress the effect of light. Light has no effect in the absence of fluorescent compds., and the dyes do not affect the sols in the dark. K. V. THIMANN

Increased bactericidal effect of inorganic compounds in the presence of x-rays. ROBERT J. NORRIS. *Bull. Basic Sci. Research* **3**, 21–36(1931).—When bacteria are irradiated in solns. contg. NaBr, NaCl, NaI, $BaCl_2$, $HgCl_2$, $UO_2(NO_3)_2$, CsI or $Th(NO_3)_4$, the resulting lethal action is very much greater than that obtained by exposing the bacteria successively to x-rays and to the salts previously irradiated with x-rays, and is a true synergistic action. This action has previously been ascribed to ultra-violet fluorescence, or to emission of photoelectrons. Expts. are described which indicate that the synergistic action of the above salts is not due primarily to these factors. The expts. indicate that the synergistic action is independent of permanent chem. decompn. For Th salts, it has been shown that at the crit. voltage for the ejection of the *K* electrons the resulting action is greatest, while theoretically the speed of the emitted *K* electrons is at a min. at this voltage; and that at a higher voltage, at

which K electrons are emitted at much greater speed, the action is much less. A tentative explanation is based upon the theory that the toxicity of the ion is related to its ionic potential or state of ionization. J. A. KENNEDY

Electron-emitting compositions. ANTON LEDERER. Austrian 120,212, Sept. 15, 1929. An electron-emitting compn. comprises more than 2% of Th incorporated into a metallic carrier consisting mainly of Os, with or without difficultly fusible metals or alloys such as W. The compn. may be coated on a wire or the like of W, or a paste contg. ThO_2, Os and a binder may be extruded to form a filament, which is then heated to a temp. above the m. p. of Th, suitably in an atm. of CO. Addnl. details are given.

Ionizing gases. ERIC DUTT. Fr. 695,016, Aug. 5, 1929. Gaseous currents are ionized to bring about chem. reactions at ordinary temps. in an elec. field produced by an alternating or pulsatory source of current the potential of which is not below 1500 v., so that the shocks of the ionized mols. between themselves liberate a sufficient amt. of energy to produce the reaction. The process may be used for the production of NO from N and O.

Photoelectric control for soaking-pit covers. R. M. BOYLE. *Elec. World* **97,** 409(1931).—A Middle West plant has a soaking-pit control which makes use of a light-sensitive relay as the initiating source. The moving crane carries only a foot-operated push-button and a light box mounted on the end of the crane for each soaking pit spanned by the crane. The layout consists of 2 soaking-pit cranes operating on a common runway and each spanning 2 pits. Preparatory to opening a cover or during the operation the crane may be shifted 5 ft. on either side of the center line and the operating lamp-box will still be opposite the light relay for that cover. To open the cover a single short flash of the lamps in the box is all that is necessary. The circuit is self-maintaining. A simple transfer circuit permits the light ray to be alternately effective to open or close the pit cover. The light-sensitive cells respond only to concd. light above the room illumination, leaving no danger of false operation. W. H. BOYNTON

Temperature compensation in electrolytes. E. BLAMBERG AND K. MÜLLER. *Arch. Elektrotech.* **23,** 435–40(1930); *Science Abstracts* **33B,** 411.—The fact that the cond. of an electrolytic cell varies rapidly with temp. as well as with concn. may be a disadvantage in some processes of deposition. The authors show how to proportion a

combined shunt *manganin* resistance and a series Cu resistance to compensate substantially for the effect of temp. G. G.

Electrolytic cells for chlorine and caustic soda. C. L. MANTELL. *Chem. Met. Eng.* 38, 88–90(1931).—Ten electrolytic cells for Cl—the Castner, Sorensen, Townsend, Hargreaves–Bird, Nelson, Allen–Moore, Buck–McRae, Gibbs, Wheeler, Vorce—are briefly described as to their constructional details, and compared. A table of operating data on the various cells has been tabulated from information furnished by users of the equipment. Yields of from 0.62 to 0.76 lb. Cl and 0.69 to 0.86 lb. NaOH per kw. hr. are in the range of com. practice. C. L. MANTELL

A note on the preparation of silver-free copper. BART PARK. *J. Am. Chem. Soc.* 52, 3165–6(1930).—The last spectrographic traces of Ag were removed from Cu by electrolyzing a soln. of 400 g. $CuSO_4$ made up to 2 l. with 5% HNO_3 between Pt electrodes with 0.05 amp. at 7 v. The Ag in the 7 fractions of deposits removed at intervals of 1–24 hrs. was estd. by Nitchie's spectrographic method (*C. A.* 23, 1587). J. D. S.

Electrolytic gold plating with high current densities. H. PAWECK AND R. WEINER. *Z. Elektrochem.* 36, 972–80(1930).—The compn. of the bath recommended for Au plating with high c. d. is 200 g. $K_4Fe(CN)_6$, 50 g. $HAuCl_4$, 50 g. anhyd. Na_2CO_3 and 1 l. of H_2O. The ppt. of basic Fe carbonate is filtered from the warm soln. and the clear filtrate serves as the electrolyte. The bath is used at 70° with rapid stirring. Gold anodes are used with the surface equal to or > that of the cathode. The cathodic c. d. is maintained at 4–6 amp./sq. dm., which corresponds to an e. m. f. of 1.2–1.5 v. when the electrodes are 4–6 cm. apart. A smooth Au plate is produced which does not require burnishing. At higher c. d. the plate is darkened. With the recommended conditions the cathodic current efficiency is equiv. to 150–190% and the anodic efficiency to 115–180%. A further study was made of the effect of varying the concn. of each of the components of the bath on the c. d.-anode potential curves. H. F. JOHNSTONE

Electrogalvanizing wires and strips at high current densities. A preliminary communication. D. V. STEPANOV, B. N. KABANOV AND N. T. KUDRYAVTZEV. *Tsvetnuie Met.* 1930, 1151–8.—Cold Zn plating has many advantages over the hot dip process, such as greater uniformity of the coating, steadiness of the bath, economy of Zn and easier control of the bath. The proposed methods of increasing the c. d. to hasten the process have serious drawbacks. The authors made about 300 expts. to find conditions essential for good results with high c. ds. Circulation of the bath permits higher c. ds. (200 to 400 amp./sq. dm.) than those used before. Different concns. of $ZnSO_4$, H_2SO_4, H_3BO_3 making up the bath were also studied, as well as the changes in the bath during the process and the suitable indicators. At 50 amp./sq. dm. it is necessary to add to a bath of 1000 l. 30 l. water, 1 kg. H_2SO_4 and 10 g. boric acid per hr. At 50 amp./sq. dm. the best temp. is 45°. At higher c. ds. the temp. should be higher. The problem of cooling the electrolyte which is heated by the current is solved by the application of air stirring; a formula is developed by which the equilibrium temp. suitable for the process can be calcd. Tables show the change of voltage with temp. and with the distance between the electrodes and a set of optimum conditions at c. ds. 50, 100 and 200 amp./sq. dm. J. G. TOLPIN

Electrodeposition of lead-thallium alloys. C. G. FINK AND C. K. CONARD, JR. *Metal Ind.* (N. Y.) 29, 116–7(1931).—See *C. A.* 24, 4989. G. G.

Polarographic studies with the dropping-mercury cathode. XVI. Electroreduction of acetaldehyde. I. SMOLEŘ. *Collection Czechoslov. Chem. Comm.* 2, 699–71 (1930); cf. *C. A.* 24, 5579.—The detection and estn. of aldehydes occurring in certain alc. beverages by their electroreduction potentials, with the dropping Hg cathode, have been previously described (Shikata and Tachi, *C. A.* 21, 1917; Shikata and Shoji, *C. A.* 22, 2895). The aim of the present work was the investigation of the mode of reduction of AcH in its pure solns., and its detn. in fermentation products. The reduction of the AcH was studied in solns. of Li salts or LiOH, since Li has the most neg. deposition potential of all cations at the dropping Hg cathode. AcH was found to be reduced at a cathode potential 0.50 v. more pos. than that at which Li is deposited from solns. of equal concn. as the AcH solns. Thus the reduction potential of AcH in a 1 M soln. is —1.60 v. The value of the reduction potential was uninfluenced by changes from a neutral to a weakly acid, or to a strongly alk., soln. Increasing acidity of the soln. hindered the electroreduction. A change in concn., c, of AcH produced a shift of the reduction potential, π, according to the formula $\pi = 0.060 \log c$ v. Math. analysis of the bend of the current-voltage curve showed that $\pi = -0.060 \log i$ (i = current), *i. e.*, $= -(RT/F)\log i$. The value of the diffusion current in 0.001 M AcH solns. was

the same as those given by 0.001 M solns. of Ba or Sr chlorides; it is, therefore, concluded that the electroreduction of 1 g. mol. of AcH requires the same amt. of electricity as is required to deposit 1 g. equiv. of Ba, *i. e.*, 1 Faraday. The probable reduction product is stated to be dimethylglycol. With this method it was found possible to est. the presence of 1 part AcH in 2 million to an accuracy of 10%. The results obtained were applied to the estn. of AcH in EtOH samples and in various vinegars. In fermented vinegars 0.001–0.002% AcH were estd. polarographically, while in synthetic or pyrolignic vinegars no traces of AcH were found. E. B. SANIGAR

Anodic oxidation of acetic acid in sulfuric acid solution. RUDOLPH SCHREINER. *Z. Elektrochem.* **36**, 953–63(1930).—In order to study the mechanism of the anodic oxidation of AcOH, solns. of oxalic, glyoxylic, glycolic, acetic and formic acids, HCHO and MeOH were electrolyzed, with a diaphragm, in 2 *N* H_2SO_4 at const. c. d. Oxidation potentials were detd., and the gaseous products were analyzed. The electrodes were Pt foil. In the AcOH series the main reactions are: $CH_3COOH \xrightarrow{+O} H_2COH{\cdot}COOH \xrightarrow{+O} HC(OH)_2{\cdot}COOH \xrightarrow{-2H} (COOH)_2 \xrightarrow{-2H} 2CO_2$, and the side reactions: $H_2COH{\cdot}COOH \xrightarrow{-2H} H_2CO + CO_2$ and $HC(OH)_2{\cdot}COOH \xrightarrow{-2H} HCOOH + CO_2$. In the MeOH series, the main reactions are: $CH_3OH \xrightarrow{-2H} H_2CO \xrightarrow{+O} HCOOH \xrightarrow{-2H} CO_2$, with $H_2CO \xrightarrow{-2H} CO$.

The data are interpreted as suggesting the following general rules for anodic oxidation of *org. compds.*: (*a*) an increase in potential favors addn. of O over the removal of 2H; (*b*) in general, the removal of 2 H atoms from the same C is easier than the addn. of O; (*c*) the difficulty of H removal increases in the order —OH,—CH,—COOH; (*d*) the simultaneous removal of 2 H mols. attached to different C atoms (in the present case 1 H was always a member of —COOH) is possible only when the H atoms are at the end of a 6-membered chain. H. F. JOHNSTONE

Electrodeposition of chromium. B. RASSOW AND L. WOLF. *Chem.-Ztg.* **55**, 73–6(1931).—An investigation of the com. prepn. "Chromprotekt," used as a protecting layer to prevent formation of chrome mists, is reported. Cf. *C. A.* **24**, 4993. C. L. W.

The acute effects of chromic acid mists. L. SCHWARTZ AND F. SEIKE. *Zentr. Gewerbehyg. Unfallverhütung* **17**, 232–4(1930).—Mists given off by Cr plating baths are the cause of ulcerations and other skin diseases among the employees. Of 233 persons examd., 42.6% had determititis, ulcers or scars and 52% showed nasal changes; of these 37 had perforation of the septum, and 79 showed ulceration or devitalization of the mucous membrane. Ulcerations of the mucous membrane were seen after 2 weeks, and perforation of the nasal septum from 6 months to 4 yrs. The authors recommend exhaust ventilation or covering the surface with petroleum or some of the less dangerous homologs of C_6H_6. Objections to these methods are liability to fire hazard and C_6H_6 poisoning. GEORGE R. GREENBANK

Modern metal cleaning. LESLIE WRIGHT AND F. TAYLOR. *J. Electroplaters' and Depositors' Tech. Soc.* **6**, 71-90(1931).—This paper is a survey of work which has been done by various experimenters upon the nature of soap solns. and the mechanism by which such solns. remove dirt. Various types of soaps, their alky., phys. properties and cleansing properties are reviewed. The evaluation of the alky. and of the detergent action of soaps is explained. The application of detergent materials to modern metal-cleaning practice is discussed. The authors are of the opinion that no one chem. cleaner is yet available which will satisfy all plating-shop requirements, so that scouring and mopping and subsequent acid dips to remove tarnish are likely to remain in general use. However, with large batches of material, which have passed through similar shop processes, a study of the grease and dirt accumulated during these processes makes it possible to devise a cleaning soln. best suited to the particular foreign materials to be removed. E. B. SANIGAR

High-voltage surge testing. F. D. FIELDER. *Elec. J.* **28**, 161–4(1931).—The cathode-ray oscillograph operation is outlined—the importance of the timing systems being emphasized. The 3-electrode gaps permit the operation of the Dufour type oscillograph for the cathode voltage within the one microsecond. The operation is simple and consistent when care is used in the circuit design and adjustment. In synchronizing circuits, the most complex system is the combination of the Dufour type oscillograph and single-sweep timing. The essential parts of the system are shown in a fig. W. H. BOYNTON

Developments in hydrogen-cooled condensers. C. J. FECHHEIMER. *Elec. J.*

28, 165–9(1931).—Success of the H_2-cooled condenser is largely due to the development of many devices for making the machine safe. Features of the machine include: (1) it has been made explosion-proof; (2) an inert gas is used for scavenging when changing from air to H_2, or the reverse; (3) the internal pressure is automatically maintained above atm. pressure to prevent air entering; (4) various alarm signals are provided to inform the operator that the internal pressure or % of H_2 is low, or that any part of the machine or auxiliaries is not performing properly; (5) suitable indicating devices are provided for the gas, water, bearings, etc., in addn. to the usual elec. instruments. Brief descriptions of these devices are given. Several illustrations and a good bibliography are included. W. H. BOYNTON

Some comments on the use of "getters." GEORGE D. O'NEILL. *Electronics* **2**, 510–11, 528(1931).—The application of the following materials as "getters" or "clean-up" agents in various types of radio tubes is considered: P, Mg, Al, Misch metal, Ba, Ca, Li, active charcoal and cerium. M. MCMAHON

Sensitizing the photoelectric cell. RICHARD FLEISCHER. *Electronics* **2**, 518–9, 530(1931).—Four requirements of photoelectric cells are instantaneous response, linear relation between light intensity and resulting electronic current, sensitivity in the visible spectrum, and constancy. Data are given showing that to increase the sensitivity of the K layer in the photoelectric cell, the K in vapor form must be brought into contact with the gas (H_2 or inert gas) present in the tube. The K is vaporized by ionic bombardment. M. MCMAHON

The cleaning of blast-furnace gas by electric precipitation; the Siemens-Schuckert system at the Falva Works of the Bismarckhütte. HERMANN BOSSE. *Stahl u. Eisen* **49**, 1153–61(1929).—By elec. pptn. in 5 filter units, the suspended matter is sepd. from 14,000 cu. m. of blast-furnace (cu. m. at 0°, 760 mm.) gas at a flow of 3.5 m./sec. The cleaned gas has a solid content of 0.01 to 0.02 g./cu. m. The d. c. at 65,000 v. is obtained by means of a transformer from an a. c. at 500 v. The moisture content of the gas is very important; if it is too low, the particles are not charged properly. The required moisture content of the gas depends also on the compn. of the gas; a high Zn and Pb content requires a higher moisture content. The gas temp. must be kept above the dew point, in order to prevent clogging of the equipment. There is a pre-cooler installed before the pptg. filters, where the gas is cooled by injection of water, followed by heating of the gas attained through combustion of part of the gas. The cost of the elec. pptn. is $^1/_6$ of that of the wet mech. pptn. at the Falva Works. J. A. SZILARD

Electro-melted cement as a new building material in the chemical industry (REDZICH) **20**. The mechanism of the action of electrical discharge upon CH_4 (PETERS, WAGNER) **3**. The hardness testing of electrodeposits (O'NEILL) **9**. Electric-furnace production of high-heat-duty refractories (SCHROEDER) **19**. MARTI, OTHMAR K., AND WINOGRAD, HAROLD: **Mercury Arc Power Rectifiers** New York: McGraw-Hill Book Co. 473 pp. $6. Reviewed in *J. Western Soc. Eng.* **36**, 63(1931).

Gas-exit for electric batteries. PRITCHETT & GOLD & E. P. S. CO., LTD., and H. M GENESE. Brit. 336,041, Aug. 9, 1929.

Manufacture of dollies for dry cell electric batteries. H. A. BUMKE GES. Brit. 337,001, April 8, 1929. Mech. features.

Manufacture of dollies for dry cell electric batteries. H. BLACHE. Brit. 337,164, April 2, 1929. Mech. features.

Batteries. OTTO BÖHM. Ger. 513,805, Jan. 17, 1930. Details are given of fastening the electric storage cells together.

Storage batteries. FRITZ HENTSCHEL. Ger. 513,807, Feb. 23, 1930. A continuous-process app. for filling dry battery cells with alk. electrolyte, comprising recessed wheels between which curved electrode strips and electrolyte are rolled, is described.

Storage batteries. Società Italiana Batterie Elettriche Cellino. Fr. 694,745, Apr. 29, 1930. Neg. electrodes are formed of sheets covered with a layer of Zn deposited electrolytically by means of an anode of Zn and in an electrolyte contg. alkali silicate.

Storage battery with sulfuric acid electrolyte. T. Standley. Brit. 336,113, Oct. 23, 1929. A H_2SO_4 electrolyte is gellified by adding 2 parts Na silicate to 5 parts of water, heating the mixt. and then adding it to 2 parts H_2SO_4 dild. with 5 parts of water.

Storage battery separators. W. R. Edwards and R. Edwards & Co., Ltd. Brit. 336,448, Oct. 30, 1929. Structural features.

Electrodes for accumulators. Fritz Hentschel. Ger. 513,806, Feb. 14, 1930. Details are given of forming electrodes for storage batteries, contg. alk. electrolytes, from blocked perforated sheets.

Metallic oxide electric rectifiers. Siemens-Schuckertwerke A.-G. Brit. 336,926, Feb. 27, 1929. The oxide layer is coated with graphite, and the latter and a lead to be attached are both smeared with a pasty soft solder compn. contg. an acid-free deoxidizing agent such as colophony to which NH_4Cl may be added; Zn is then sprayed onto the oxide layer to form a coating, melt the solder and unite the oxide layer and the lead.

Electric condensers. Hermsdorf-Schomburg-Isolatoren Ges. Brit. 336,990, July 18, 1929. Multi-part insulator-condensers are made so that the outer part forming the insulator is of a material of high mech. and thermal strength such as porcelain, steatite, stoneware or quartz glass, while the material such as glass of the inner condenser part has a high breakdown strength and the highest possible dielectric const. (even if this involves a lessened mech. or thermal strength).

Electrodeposition of copper. A. Mozer. Brit. 336,109, Oct. 29, 1928. In operations such as plating, manuf. of electrotypes and refining of black copper, an electrolyte contg. Cu_2I_2 is employed; *e. g.*, Cu_2I_2 60, KI 600 and water 1000 parts may be used with an addn. of 5–10 parts of a colloid such as glue or gelatin or of a substance having capillary activity such as phenol or tannin. A c. d. of 400 amps. per sq. meter at 0.3 v. is suitable.

Electroplating materials such as feed-mill screens with metals such as chromium. Richard Stresau (to Swifton Mfg. Co.). U. S. 1,792,197, Feb. 10. The electrolyte in which an anode is immersed is caused to circulate through the interstices of the material, which is connected as cathode, and at the same time elec. current is passed through the electrolyte to effect plating of the interstices of the material as well as of its exterior surface. App. is described.

Coating objects with chromium. Metals Protection Corporation. Ger. 513,742, July 3, 1927. See Fr. 640,913 (*C. A.* **23**, 1065) and Brit. 277,295 (*C. A.* **22**, 2331).

Nickel and chromium coatings on foundation metals such as iron or steel. Colin G. Fink and Li Chi Pan (to Chemical Treatment Co.). U. S. 1,792,082, Feb. 10. A heat-treated plate of Ni on the foundation metal is provided with an overlying plate of Cr.

Stripping off chromium plating. J. F. McCullough (to Ternstedt Mfg. Co.). Brit. 336,532, March 6, 1929. See Ger. 511,416 (*C. A.* **25**, 1167).

Plating aluminum. Louis Schulte. U. S. 1,791,642, Feb. 10. The surface of an Al article is "passivified" (suitably by treatment with HNO_3), and the prepd. surface is plated with an alloy of Ni and Fe by electrodeposition in a bath contg. sulfates of Ni and Fe and a cond. salt such as Na_2SO_4, and the coating thus formed is then further plated with a finishing metal such as Ag, Au, brass, Cu, bronze or Ni.

Electrolysis. Otto Lefnaer. Austrian 120,400, July 15, 1930. In pptg. metals from soln. by electrolysis, the cathodes used are made of Fe (or an Fe alloy) that has been converted superficially into the nitride. A nitrided Fe-Cr alloy is instanced. The electrolyte must not be too acid. The pptd. metals are readily removed.

Electrolytic cells. Joseph L. Woodbridge. Ger. 513,941, Nov. 29, 1927. An arrangement for insulating the electrodes is described.

Electrolytic cells such as those for producing oxygen and hydrogen. A. E. Knowles. Brit. 335,987, July 6, 1929. Liquid level in an electrolytic gas generator is maintained by flow from a tank, which is fed with electrolyte from gas-washing chambers, and delivery of fresh liquid to the washing chambers is controlled by a float in the tank. Various details of app. are described. Cf. *C. A.* **25**, 1167.

Electrolytic production of hydrogen peroxide or other compounds containing active oxygen. Erich Noack, Oswin Nitzschke and Georg Pfleiderer (to I. G. Farbenind. A.-G.). U. S. 1,792,389, Feb. 10. See Brit. 316,648 (*C. A.* **24**, 1805).

Acetylene. CONSORTIUM FÜR ELECTROCHEMISCHE INDUSTRIE G. M. B. H. Fr. 694,109, Apr. 17, 1930. C_2H_2 is made by submitting a current of CO or CO_2 or both mixed with H or hydrogenated compds. to the action of high tension elec. discharges, preferably under reduced pressure.

Formaldehyde. GUTEHOFFNUNGSHÜTTE OBERHAUSEN A.-G. Fr. 694,330, April 23, 1930. CH_2O is made by passing a mixt. of CH_4 and CO_2 or gases contg. these through an elec. field produced by an elec. current of high tension and frequency. Cf. *C. A.* **24**, 5241.

Decomposition of water. YUJI MORISHIMA. Fr. 694,346, April 23, 1930. An app. is described for decomposing water into H and O, in which water from a chamber can flow into a very narrow space between 2 of 3 coaxial tubes forming a chamber in which the water is vaporized by heat from an elec. heating element disposed in the central tube. The vapor thus produced is introduced into a decompn. chamber in which it is decomposed into its constituents by another heating element.

Electrolytic manufacture of salts. JEAN ALAS. Fr. 694,918, Jan. 15, 1930. Sol. salts of metals placed at the anode are made with the acid salt of alkali metals as electrolyte. The process may be used for making sol. sulfates of Cu, Fe, Al, Ni and Zn and also phosphates, chlorates, perchlorates and persulfates.

Alumina. GINO GALLO. Fr. 694,885, May 2, 1930. Leucite or other silicates contg Al and K or Na or natural or artificial salts of Al are treated to obtain SiO_2, Al_2O_3 and salts of K or Na in a very pure state, by making a soln. of a K- or Na-alum and submitting the soln. to electrolysis to obtain H_2SO_4 at the anode and $NaAlO_2$ or $KAlO_2$ at the cathode. An excess of alkali sulfate is used to facilitate the formation of the corresponding aluminate. The anode may be of Pb and the cathode of Fe.

Zinc. I. G. FARBENIND. A.-G. Fr. 694,234, April 19, 1930. Max. yields are obtained in the electrolysis of $ZnSO_4$ solns. by maintaining the circulating electrolyte at the most favorable compn. for the working conditions, each individual vat of the app. being charged directly from the circulating vessel.

Electric furnace. EMIL F. RUSS. Ger. 513,762, Aug. 5, 1927.

Electric furnaces. AKT.-GES. BROWN, BOVERI & CIE. Ger. 516,397, June 8, 1926. Means is described for insulating the electrodes against the electrode-moving device.

Electric furnaces. SIEMENS-PLANIAWERKE A.-G. FÜR KOHLEFABRIKATE. Fr. 694,428, April 25, 1930. Mounting of electrodes is described.

Electric induction furnaces. I. G. FARBENIND. A.-G. (Emil Fendt and Carl Schörg, inventors). Ger. 513,689, Dec. 29, 1928. The spools and rolls, etc., carrying the heating filaments are rendered sufficiently resistant to heat by making them of asbestos-insulated wire impregnated with a cement mass of fluosilicate.

Electric induction heating of apparatus such as that for treating oils or further oxidation of litharge. EDWIN F. NORTHRUP (to Ajax Electrothermic Corp.). U. S. 1,791,934, Feb. 10. Coils and elec. connections are arranged so as to provide sections for regulated differential heating.

Electric resistance furnace. W. J. MILLAR and ELECTRIC FURNACE CO., LTD. Brit. 336,097, Oct. 8, 1929.

Electric resistance furnace for carrying out exothermic reactions. ALLGEMEINE ELEKTRIZITÄTS-GES. (Viktor Paschkis, inventor). Ger. 513,542, Sept. 27, 1927.

Electric resistance furnace for annealing or other heat treatments. P. CARLBERG. Brit. 336,078, Sept. 23, 1929. Structural features. A cooling medium may be circulated through the resistance, tubular in form, when the heating is completed.

Electric resistance furnace for firing enameled gooda. C. L. IPSEN and J. L. MCFARLAND (to British Thomson-Houston Co., Ltd.). Brit. 336,168, Dec. 18, 1929. Structural features.

Electric furnace with resistance heaters under the hearth. ALLGEMEINE ELEKTRIZITÄTS-GES. Ger. 516,396, Mar. 1, 1929.

Apparatus for regulating the position of electrodes of tilting electric furnaces. HENNING G. FLODIN. U. S. 1,792,293, Feb. 10. Structural features.

Electric heating elements. C. B. BACKER. Brit. 336,949, June 22, 1929. Mg is applied to a wire in the form of 2 or more longitudinal strips bent in arcuate form so that the strips form a tube about the wire, and the Mg is converted into MgO by the action of steam, a resistance element embedded in the MgO and provided with an outer casing being formed.

Electric smelting oven. EMIL F. RUSS. Ger. 516,190, Mar. 5, 1929. Addn. to 504,419 (*C. A.* **24**, 5241).

Acetylene and hydrogen by electric arc treatment of saturated hydrocarbons.

I. G. FARBENIND. A.-G. Brit. 337,088, Aug. 7, 1929. See Fr. 674,459 (*C. A.* **24**, 2385). Gases such as CH_4, C_2H_6, natural gas, distn. gases from coal, shale or peat, cracking gases, oil or tar vapors, or gases contg. nebulized carbonaceous materials such as tar oils or coal dust (which may be assocd. with H or with small quantities of N, CO or CO_2) are passed through a series of arcs, the lengths of which are adapted to the changing compn. of the gas so that longer arcs are used as the concn. of hydrocarbons decreases. Various details and examples are given.

Thermal decomposition of methane, etc. I. G. FARBENIND. A.-G. Brit. 336,261, July 10, 1929. Gases such as CH_4 or natural gas are decompd. (for production of C_2H_2, carbon black and H) by passage through an elec. arc at a temp. of about 2500° or higher, so that the ratio of the quantity of gas (measured in cu. meters per hr.) to the power of the arc, in kilowatts, lies below 0.6.

Iron cores for electrical purposes. WEITVERKEHRSKABEL G. M. B. H. (Walther Ehlers, inventor). Ger. 513,761, Dec. 24, 1927. Fe powder, *e. g.*, obtained by electrolysis, is pressed at 20,000 to 30,000 atm.

Electrical gas purifiers. METALLGES. A.-G. Fr. 694,603 and 694,604, April 28, 1930. Electrodes and means for suspending them are described.

The purification of gases and the manufacture of fertilizers. SOCIÉTÉ BELGE D'ELECTRO-SYNTHÈSE "SOBELSYN." Belg. 371,622, Aug. 31, 1930. Solid fertilizer is obtained electrolytically. The electrolyte consists of a soln. of some basic salt, preferably liquors contg. CO_2 in some form and org. matter such as ammoniacal liquors from the gasification of coal, liquid manure, etc. A graphite or retort C anode is used. Cf. *C. A.* **25**, 1062.

Electrical purification of blast-furnace gas. SIEMENS-SCHUCKERTWERKE A.-G. Fr. 694,219, April 19, 1929.

Alloy armoring for electric cables. W. T. HENLEY'S TELEGRAPH WORKS CO., LTD., and P. ROSLING. Brit. 336,408, Oct. 3, 1929. For reducing armoring losses in single-core a. c. cables, the armoring is formed of an alloy of Al contg. also Mg 0.4–0.5, Si 0.5–0.6 and Fe about 0.3%.

Loading material for electric cables. STANDARD TELEPHONES & CABLES, LTD., and T. N. RILEY. Brit. 336,626, July 17, 1929. Dissimilar loading materials are used on different portions of a cable, the sections (such as the end sections) to be used at greater energy level being loaded with material of constant permeability over the normal working range (such as Ni 45, Fe 30 and Co 25%) and the intermediate portion being loaded with material of high resistivity (such as Ni 78.5, Mo 3% and the remainder Fe).

Temperature-indicating device for oil-immersed electrical apparatus such as transformers. GENERAL ELEC. CO. and BRITISH THOMSON-HOUSTON CO., LTD. Brit. 336,431, Oct. 14, 1929. Structural features.

Metallic-vapor lamps. N.-V. PHILIPS' GLOEILAMPEN FABRIEKEN. Brit. 336,208, July 5, 1929. Various structural details are described of elec. discharge tubes contg. an alloy or mixt. of metals such as a Cd amalgam, which preferably constitutes an electrode of the tube.

Electric neon lamps. CLAUDE NEON LIGHTS, INC. Brit. 336,956–7, July 18, 1929. Structural and elec. features.

Electric incandescent lamps. N.-V. PHILIPS' GLOEILAMPEN FABRIEKEN. Brit. 335,903, July 1, 1929. Various structural details are given of a lamp having a "concentrated" W filament assocd. with Hg or like material inert to W in a bulb allowing the Hg to circulate and which also may contain gases such as N or A. Cf. *C. A.* **25**, 1449.

5—PHOTOGRAPHY

E. P. WIGHTMAN

New processes of color photography. G. GROTE. *Phot. Korr.* **66**, 177–81(1930).—A review is given of the subject matter of all the patents issued in 1929 for additive (screen), subtractive or direct color processes. E. R. BULLOCK

Photography in the infra-red. W. DIETERLE. *Phot. Korr.* **66**, 309–15(1930).—After an historical account of progress in infra-red photography by means of filters and suitably sensitizing dyes, from the discovery of dicyanine to the present time, D. describes its applications to distance photography, to night-effect exposures (with Kodak or Agfa film), to spectrophotography and photomicrography in the infra-red and to the photography of substances at temps. below a visible red heat. Working prescriptions are given for the infra-red sensitizing of ordinary high-speed plates and films and for the

hypersensitizing of the purchaseable Kodak or Agfa infra-red sensitive plates. A suitable light filter, especially suitable for the purpose of the exposure, must be used, and development may be carried out by a feeble green light. E. R. BULLOCK

Filter solutions for fluorescence photography. K. WEBER. *Phot. Korr.* **66**, 317–9 (1930).—A 2% aq. soln. of $NaNO_2$ in a thickness of 1 cm. in a glass cell absorbs ultraviolet radiations of 366 mμ almost completely. W. gives comparative illustrations of fluorescence photography with a $NaNO_2$ filter and with "G. G." (Schott & Gen.) solid glass filters; the latter, though the most suitable of that kind available, do not absorb ultra-violet nearly as satisfactorily as does the former. E. R. BULLOCK

Photographic hardness and absorption measurements of x-rays. L. GREBE AND W. SCHMITZ. *Z. wiss. Phot.* (*Schaum Festschrift*) **29**, 129–33(1930).—By comparing x-ray exposures made through an Al step tablet with those made sensitometrically one may compute from the absorption law the effective wave length of a heterogeneous beam. The method is the same in principle as the ionization method. H. E. S.

The concentration speck or centripetal theory of light action. A. STEIGMANN. *Kolloid-Z.* **53**, 318–22(1930); cf. *C. A.* **24**, 30; **25**, 44.—The theory is applied to the mechanism of the action of light on photographic plates. ARTHUR FLEISCHER

Sensitiveness of photographic dry plates. M. MIYATA. *Mem. Coll. Eng., Kyoto Imp. Univ.* **6**, No. 2, 113–78(1930).—A possible addnl. cause of the sensitivity of the dry plate is presented. It is found that AgCl is always present with AgBr at its pptn. and it is presumed that the AgCl grains are the sensitive centers in the AgBr crystals. Further expts. show that AgBr and AgI in photographic emulsions act as both chem. acceptors and optical sensitizers for AgCl nuclei. Ripening of an emulsion is the result of the adhesion of AgCl and AgBr crystals sepd. at pptn. by gelatin. L. A. STAIF, JR.

The accumulation effect of photographic plates and its influence on the accuracy of photographic photometry. N. BARABASCHEFF AND B. SEMEJKIN. *Z. wiss. Phot.* **28**, 333–40(1930).—The accumulation of photographic density (growth of the latent image) is real and must be taken into account in photometry. It is advisable to develop plates at least 2 days after exposure; otherwise systematic errors which influence the results are introduced. Old plates show this accumulation effect to less extent than new plates. A P. H. TRIVELLI

Reproduction of negatives. P. HANNEKE. *Camera* (Luzern) **9**, 155–7(1930).—A AgBr plate or film is bathed in 4% $K_2Cr_2O_7$ soln., dried and exposed under the negative to be copied until a faint brown image is visible. The duplicate is then washed and finally developed by ordinary light, in a regular photographic developer. The unexposed portions develop, giving a duplicate negative. The contrast can be controlled by the length of exposure or by a subsequent flash exposure. M. W. SEYMOUR

Dyes unstable to light are sought. H. HERMSDORF. *Camera* (Luzern) **9**, 160–4 (1930).—The theory and history of color printing processes by means of bleach-out dyes are briefly described. The problems to be solved in the improvement of the bleach-out process are said to be increasing the sensitivity and working out a good means of fixation. A process useful practically requires plates or papers that will keep for at least 6 months to a year. M. W. SEYMOUR

Role of dyes in the progress of photography. A. SEYEWETZ. *Photo-Revue* **42**, 353(1930).—In the application of dyes to photography the following uses have been found: (1) chromatic sensitizing of photographic negative materials; (2) photographic reproduction of colors; (3) lighting of the darkrooms and the chromatic desensitizing of plates; (4) prepn. of antihalo plates; (5) tinting of plates and films for transparencies; (6) prepn. of colored motion pictures; and (7) production of photographic images with diazo compds. Most of the dyes which are used for the chromatic sensitizing of photographic materials belong to the following types: (1) diphenylmethane, (2) triphenylmethane, (3) acridine, (4) phenylacridine and (5) quinoline. A description including the spectral region which they sensitize is given for several dyes. *Ibid* 375(1930).—The cyanine dyes used as sensitizers for photographic materials are classified into 4 groups: (1) the cyanines, (2) the isocyanines, (3) the pinacyanols and (4) the dicyanines. A brief description is given for several dyes belonging to each class. The use of desensitizing dyes after exposure in order to permit inspection with a bright light during development was introduced by Lüppo-Cramer with the discovery of phenosafranine and has led to a study of the desensitizing properties of other dyes. Certain dyes which sensitize Ag chloride and bromide emulsions were found to desensitize Ag iodide emulsions. *Ibid* **43**, 5–7, 23–4(1931).—No direct relation exists between the constitution of a dye and its desensitizing properties. All of the safranines, however, which contain amino groups have desensitizing properties. The expts. of Lumière and Seyewetz have indicated that the desensitizing action of phenosafranine is

due to the formation of an adsorption complex between the AgBr and the dye which is not sensitive to light and is slowly destroyed by washing. Lüppo-Cramer considers that the desensitizing action is due to the oxidation by the dye. Dyes are used in the prepn. of films and plates for the suppression of photographic halation due to reflection. In this case the dye is incorporated in the subcoating between the sensitive emulsion and its support or is applied as a dyed gelatin backing. One of the most important uses of dyes has been in the photographic reproduction of color by the indirect method. A practical discussion with formulas is given for this process on the selection of the dye and the dyeing of the monochromes. H. D. RUSSELL

Acceleration of development by neutral salts and dyes. LÜPPO-CRAMER. *Phot. Korr.* 66, 253–6(1930).—L.-C. for the first time gives density curves to illustrate the phenomenon of acceleration of development by the addn. to the hydroquinone or other developer of large amts. of neutral salts or relatively very small quantities of certain basic dyes. Plates of very contrasty emulsion (not further described) were used, and the standard developer was hydroquinone with sulfite, K_2CO_3 and KBr. With these the effect of KNO_3 (10%) or of pinakryptol green (0.005%) is very conspicuous. As regards theory, L.-C. remarks that the action of the neutral salts and also, though there are some exceptions and contradictions in this case, that of basic dyes, recalls their coagulating action on such suspensions as colloid Ag. The exceptional difference between the action of pinakryptol green and pinachrome, the latter producing fog and a relatively flat gradation, is illustrated. E. R. BULLOCK

Fine grain developers and their application to spectrography. EMILIO VITERBI. *Nuovo cimento* [N. S.], 6, 36–9(1929); *Proc. 7th Intern. Congr. Phot.* 1928, 365–7. E. J. C.

The role of sulfite in photographic developers. J. RZYMKOWSKI. *Camera* (Luzern) 9, 128–32, 164–7(1930).—Evidence is adduced from the literature and from original exptl. work to show that the protective action of sulfite against the aerial oxidation of hydroquinone developers can be explained by the following series of reactions: (1) $C_6H_4(OH)_2 + O \longrightarrow O{:}C_6H_4{:}O[+ H_2O]$; (2) $3Na_2SO_3 + H_2O \longrightarrow 2Na_2SO_4 + S + 2NaOH$; (3) $S + Na_2SO_3 \rightleftharpoons Na_2S_2O_3$; (4) $O{:}C_6H_4{:}O + Na_2S_2O_3 + H_2O \longrightarrow (HO)_2C_6H_3SSO_3Na + NaOH$; (5) $(HO)_2C_6H_3SSO_3Na + NaOH \longrightarrow Na_2SO_3 + (HO)_2C_6H_3SOH$; (6) $(HO)_2C_6H_3SOH + O_2 + NaOH \longrightarrow (HO)_2C_6H_3SO_3H + H_2O$. The hydroquinone-sulfite complex previously assumed by Mees and Piper (*Brit. J. Phot.* 1912, 441–3) to explain the fogging action and minimal cond. of hydroquinone developers with a deficiency of sulfite is believed to be the hydroquinone monothiosulfonic acid formed in equation 4. The occurrence of hydroquinone disulfonic acid in oxidized hydroquinone developers is explained by assuming that the monosulfonic acid, formed in equation 6, undergoes the same series of reactions as the hydroquinone itself. M. W. SEYMOUR

A critical examination of the Hübl system of color sensitometry. E. HEISENBERG AND M. BILTZ. *Phot. Korr.* 66, 169–76, 198–203(1930).—H. and B. find that the color reproduction of materials calcd. according to the Hübl system agrees with the true color reproduction within an error of at most 20%. The variation of emulsion gradation (gamma) with the filter (wave-length range) needs to be taken into consideration; the unsharpness of cut of the filters, and the variation in color sensitivity of the emulsion within the limits of transmission of any one of the filters are, on the other hand, generally practically negligible. E. R. BULLOCK

Solarization. IV. Dependence of solarization upon the preparation of emulsions. H. ARENS. *Z. wiss. Phot.* 28, 341–7(1930); cf. *C. A.* 25, 651.—An emulsion freshly prepd. from a peptized Ag compd. solarizes a little or not at all. After some time the power to solarize increases. This increase is greater the less the concn. of Ag ions. If they are removed as far as possible by KBr, in a few seconds the emulsion acquires the power to solarize very strongly. This process is irreversible. A. P. H. TRIVELLI

Constancy of the amount of light in magnesium foil sensitometry. G. SCHWARZ AND F. URBACH. *Phot. Korr.* 66, 261–4(1930).—Using a micro-burner for igniting the Mg and a Rb and a K photoelectric cell for measuring the light, S. and U. conclude from the results of their expts. that Mg foil as prescribed by Eder (cf. *C. A.* 23, 4153) gives a practically const. source of light sufficient for this kind of sensitometry. It is necessary, however, by const. manipulation to diminish fluctuations in the light and also to take the mean of several measurements to bring the residual accidental error below that of the Eder-Hecht sensitometer. E. R. BULLOCK

Physics of the washing-out of hypo from prints. R. E. LIESEGANG. *Phot. Korr.* 66, 324–6(1930).—Expts. with ferrous NH_4 sulfate and with $CuCl_2$ suggest that, in consequence of the high osmotic pressure, hypo is removed in the washing process

from fixed prints more quickly than would be expected on the basis of simple diffusion.
E. R. BULLOCK

Displacement of silver in partly swollen gelatin layers. E. WAGNER AND K. SCHAUM. *Z. wiss. Phot.* 28, 325–7(1930).—A drop of water on a photographic plate or film causes a spot after development, in which the edges have higher densities than the center. This is due to a displacement of the gelatin contg. Ag halide grains to the edge of the wetted spot. The extent to which the real Ag density or addnl. light reflections cause the dark edge can be investigated by detg. the edge density after immersing the surface of the film or plate in glycerol. It is shown that even in that case the edges have a higher density, because of migration of Ag halide to the edge of the spot.
A. P. H. TRIVELLI

Hydrolyses occurring in washing of the gelatin-silver nitrate system. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* 28, 328–32(1930).—Lüppo-Cramer had observed that in the gelatin system plus $AgNO_3$, hydrolysis takes place. The authors made a quant. investigation of this phenomenon as a support for their theory that during pptn. of Ag halides in gelatin, some Ag is formed by the action of $AgNO_3$ on gelatin. The hydrolysis of $AgNO_3$ in the presence of gelatin gives Ag_2O and HNO_3, which Ag_2O is retained by gelatin.
A. P. H. TRIVELLI

Stability of the latent image of a silver iodide emulsion toward dichromate-sulfuric acid. H. H. SCHMIDT. *Phot. Korr.* 66, 315–7(1930).—S. distinguishes 2 latent light images; one occurs in AgI-gelatin emulsion formed with excess of sol. iodide, the other in emulsions formed with excess of Ag salt. The former latent image is found to be very unstable and readily destroyed by solns. of oxidizing agents, while the latter is stable even toward dichromate-sulfuric acid. The latter is, moreover, not susceptible of intensification by nucleus denudation, but is, on the contrary, apparently somewhat diminished for phys. development, by the action of an intermediate bath of KI.
E. R. BULLOCK

Photographic effects of γ-rays (ROGERS) 3. Manufacture of photographic lenses (GUILFORD) 19. Photographic sound records (Brit. pat. 336,559) 18.

Color photographs. LOUIS DUFAY (to Old Jewry Trust, Ltd.). U. S. 1,792,418, Feb. 10. In a process for the reproduction of color photographs on a transparent film bearing only one sensitive layer on each of its faces, the sensitive layers are impregnated with tartrazine, corresponding neg. plates are simultaneously applied on each of the sensitive layers, and the film and neg. plates are exposed to light, and the film is subsequently washed to eliminate the tartrazine and the layers are differently colored.

Color photography. J. N. GOLDSMITH, T. T. BAKER and SPICERS, LTD. Brit. 337,073, July 30, 1929. A film of material such as celluloid, viscose or the like, to which a multicolor screen is to be applied by dyeing, applying a resist pattern, bleaching and redyeing the parts unprotected by the resist, is preliminarily coated with an isolating layer of substantially waterpoof character, such as a synthetic resin or cellulose acetate varnish, and a surface layer of material such as collodion or cellulose prepd. from viscose which is receptive to dyes.

Color photography. T. T. BAKER, A. B. KLEIN and COLOUR SNAPSHOTS (1928), LTD. Brit. 337,057, July 27, 1929. A "tripack" is formed with a green-sensitive front layer, a blue-violet-sensitive intermediate layer, a red-sensitive rear layer and (in order to protect the rear layer from green and blue-violet light) filters preferably comprising a green-absorbing filter between the front and intermediate layers and a blue-violet-absorbing filter between the intermediate and rear layers. Various details of manuf. are described.

Color photography. T. T. BAKER. Brit. 337,040, July 25, 1929. In a process of obtaining prints in natural colors in which a light-sensitive layer coated over a multicolor screen on a transparent support is printed through the support from a negative assocd. with a multicolor screen (the image and screen being subsequently transferred to an opaque support with the screen uppermost), the screen is printed on a celluloid, cellulose acetate, regenerated cellulose, collodion or gelatin layer attached by an adhesive such as gum dammar to a translucent stripping support such as celluloid or parchmentized paper. The final support may be paper, a cellulose acetate film contg. baryta or material such as is described in Brit. 282,980 (*C. A.* 22, 3848) which is coated with an adhesive such as gum arabic. Brit. 337,041 describes a process in which, to avoid the moiré effect in copying by projection from a master cinematograph film, a sheet of plane glass scored or indented with lines is placed in front of, or behind, the

projection lens. The lines may be formed as concentric circles about 0.125 in. apart. Cf. *C. A.* **24**, 5245.

Color photography. I. G. FARBENIND. A.-G. Fr. 694,031, April 16, 1930. Color images are obtained on films with microscopic lenticular gratings by producing, during the taking of the view, all the images of the colored screen in the layer of emulsion so that they coincide with the central axis of the corresponding lenticular elements.

Photographic layers. PHILIPPE FRANGIALLI and GEORGES H. A. FREYSS. Fr. 695,006, Aug. 2, 1929. Layers sensitive to light are made on suitable supports by using as sensitive material diazonium salts of aromatic amines which contain the imidazole group, simple or substituted, mixed with an azo compd. of phenolic or aminophenolic properties and adding, according to the case, an acid which does not deteriorate the support. Thus, Schaeffer acid and oxalic acid are added to a soln. of diazotized *N*-methyl-*C*-methylaminobenzimidazole and the mixt. is used for coating supports which are then dried. Other examples are given.

Photographic surfaces. JOS-PB FARBENPHOTO G. M. B. H. (Gustav Koppmann, inventor). Ger. 513,277, Feb. 17, 1929. See Brit. 327,283 (*C. A.* **24**, 4996).

Photographic films from mixed cellulose esters. C. S. WEBBER and C. J. STAUD (to Kodak, Ltd.). Brit. 336,353. Mixed esters are employed which contain an acyl radical and a radical of an acid contg. a hydroxy group in the α-position or a ketonic group in the α- or γ-position and which are sol. in acetone or its homologs or in 50–75% aq. alc. soln. and these esters are dissolved in a mixt. of ethylene chloride and a monohydroxy aliphatic alc. contg. 5 C atoms or less.

Combined cinematograph and sound record films. T. T. BAKER. Brit. 335,899, July 1, 1929. Before application of the resean to the surface of the film, the narrow marginal strip which is to serve as the sound track is protected from the dyes in the resean by application of a layer of protecting varnish such as a soln. of bitumen in C_6H_6. The resean is then applied to the whole surface of the film, followed by treatment with a varnish-removing solvent, so that a strip of clear uncolored film is provided to receive the sensitive emulsion upon which the sound record can be photographed in black and white.

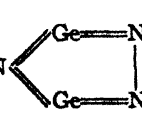
Fire-resistant motion picture films. ARTHUR ARENT (to Arthur Arent Laboratories, Inc.). U. S. 1,792,457, Feb. 10. Films are treated with a soln. prepd. from urea and $SbCl_3$ or from other suitable acid-binding org. compd. which does not promote inflammability and a suitable acid-yielding fire-retardant metal salt, applied in a substantially non-aq. solvent such as EtOAc.

Photographic developers. I. G. FARBENIND. A.-G. (Gustav Reddelien and Werner Müller, inventors). Ger. 516,030, Jan. 8, 1930. Addn. to 454,839. *N*-Monohydroxypropyl and *N*-monohydroxybutyl derivs. of *o*- and *p*-aminophenol and their nuclear substitution products not contg. NO_2 groups are used as the active constituents of developing solns. for Ag halide layers. A suitable soln. comprises *p*-(hydroxypropylamino)phenol-HCl 1, Na_2SO_3 9 and K_2CO_3 8 g. in H_2O 200 cc. Cf. Ger. 467,818 (*C. A.* **23**, 572).

Transforming photographic silver images. F. LIERG. Brit. 335,930, July 2, 1929. The opaque substances such as AgBr or Ag are converted into transparent complex compds. having strong mordanting properties by treatment with a reagent such as an iodide, urea, thiocyanate or thiocarbamide and other substances such as bisulfites may also be added which react with the complex-forming reagent. Various details and examples are given.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON



The isomerism of radicals. CLEMENT DUVAL AND MME. CLEMENT DUVAL *Compt. rend.* **191**, 843–5(1930); cf. *C. A.* **24**, 563.—A special study was made of the isomeric ions $[CoSO_4(NH_3)_5]^-$ and $[CoSO_4(NH_3)_5]^{--}$. Persulfatepentammine sulfate has a d. of 2.1 and a mol. susceptibility of -588×10^{-6}. Sulfatepentammine sulfate is red, has a d. of 1.7 and a mol. susceptibility of -212×10^{-6}, measured at 15°. Both give the same product on hydrolysis in dil. soln. GERALD M. PETTY

The coördination value of multivalent negative radicals. PAUL PFEIFFER. *Z. anorg. allgem. Chem.* **192**, 366–8(1930).—If it is assumed that Co has a const. coördination no. of 6, certain bivalent radicals sometimes have a coördination value of 1 and sometimes of 2, as follows: $[(H_3N)_5Co(CO_3)]X$ and $[(H_3N)_4Co(CO_3)]X$. These can be satisfactorily explained by the following distribution of charges on dissocn.: $^{++}[(H_3$-

N)$_5$Co—O—CO—O$^-$] + X$^-$, $\left[(H_3N)_4Co\begin{smallmatrix}O\\O\end{smallmatrix}>CO\right]^+$ + X$^-$. The following general statement can be made: bivalent acid radicals take 2 coördination positions in the uncharged condition and only 1 coördination position when carrying a single neg. charge. If 2 neg. charges are carried, then the coördination no. of the radical is zero. H. STOERTZ

The mechanism of precipitation changes. I. The reaction between lead chloride and ammonium chromate. Z. KARAOGLANOV AND B. SAGORTSCHEV. *Z. anorg. allgem. Chem.* **194**, 151–8(1931).—$PbCrO_4$ pptd. in the presence of HCl contains Cl, whose quantity varies with the concn. of Cl^-, the time required for complete pptn. and the temp. The Cl held by the ppt. does not appear to be volatile at high temps. When HNO_3 is present no nitrate could be detected in the ppt. No dichromate was found in either case. The Cl is believed to be held as $Pb_2Cl_2CrO_4$ (cf. *C. A.* **24**, 4690). The results are reproducible only with carefully controlled conditions. **II. The reaction between sulfuric acid and lead bromide.** *Ibid* **195**, 105–12.—Pptn. of $PbCrO_4$ with $PbBr_2$ gives the same results as with $PbCl_2$. The reproducibility of the results depends on the length of time the ppt. stands in the soln. The longer the time the less the Br in the ppt. **III. Further investigations of the reaction between sulfuric acid and lead bromide.** *Ibid* 113–20.—The decrease in Br content of the ppt. which occurs when the ppt. is not immediately filtered has been studied. There appears to be a metastable Br-contg. product which is not a mixed crystal, solid soln. or abs. compd. but rather a complex of the type $(PbBr)_2SO_4$ which decomposes on standing in soln. to give $PbSO_4$ and $PbBr_2$. J. B. AUSTIN

Investigations on cerium. LEON LORTIE. *Ann. chim.* [10], **14**, 407–60(1930).—Ceric salts (valence 4) dissolve in alkali carbonates to form complex salts. The ceric carbonate of Na, $[Ce(CO_3)_5.(H_2O)_2]Na_6.10H_2O$, has been sepd. as yellow crystals and analyzed. It decomposes in H_2O to cerihydroxy carbonate, $CeCO_3(OH)_2$. Although K, NH_4, Li and Tl form similar compds., they could not be crystd The Na salt is isomorphous with the Na thoricarbonate, $[Th(CO_3)_5(H_2O)_2]Na_6.10H_2O$. Tl, Zr and Ti salts show similar reactions. Cerous tartrate (valence 3), $Ce_2(C_4H_4O_6)_3$ 6-H_2O or $Ce_2(C_4H_4O_6)_3.4^1/_2H_2O$, dissolves in halogen acids to form complex acids as cerous chlorotartrate, $Ce_2(C_4H_4O_6)_3.3HCl.14H_2O$, and cerous bromotartrate, $Ce_2(C_4H_4O_6)_3.3HBr.14H_2O$. With tartaric acid it forms cerotartaric acid, $Ce(C_4H_4O_6)_2H.2H_2O$, which is able to form the Na cerotartrate, $Ce(C_4H_4O_6)_2Na.8H_2O$. In alk. tartrates it forms ceric compds., which are subsequently reduced by the tartrate to cerous compds. With excess O unstable perceric compds. (valence 6) form. Cerous tartrate dissolves in alkalies to form salts as K ceritartrate, $2CeO(C_4H_2O_6)K_2.C_4H_4O_6K_2.11H_2O$. These are red crystals sol. in water, bases and acids. With Na salicylate cerous salts give perceric salicylate, $Ce_2O_3(C_6H_4.CO_2.O)_3.6H_2O$. A. LE V.

Germanium. VIII. The action of ammonia on germanium tetrachloride: germanium imide. JOHN S. THOMAS AND WM. PUGH. *J. Chem. Soc.* **1931**, 60–71; cf. *C. A.* **24**, 2391.—The principal object of this investigation is to det. whether $GeCl_4$ 6-NH_3 is a pure compd. or whether it is a mixt. of $Ge(NH)_2$ and NH_4Cl. Since $Ge(NH)_2$ is readily hydrolyzed when exposed to traces of H_2O vapor, an all-glass app. is described in which $GeCl_4.6NH_3$ can be prepd., washed with liquid NH_3, dried and weighed, without opening at any stage. Thus, $Ge(NH)_2$ of 97.2% purity was prepd. By means of liquid NH_3, $GeCl_4.6NH_3$ was broken up into 1 mol. $Ge(NH)_2$ and 4 mols. NH_4Cl; thus it is a mixt. rather than a mol. compd. of $GeCl_4$ and NH_3. The existence of $Ge(NH)_2$ as an intermediate product of the action of NH_3 on $GeCl_4$ above −20° could not be confirmed. When HCl is passed over $Ge(NH)_2$ the addn. compd. $Ge(NH)_2$ 2-HCl is first formed; this then combines with 4 mols. of HCl to form $GeCl_4$ and NH_4Cl The action of heat (up to 300°) on mixts. of $GeCl_4$ and NH_4Cl was studied. The results are explained on the assumption that HN  is formed. J. BALOZIAN

The chemistry of germanium. ROBERT SCHWARZ, P. W. SCHENK AND H. GIESE. *Ber.* **64B**, 362–8(1931); cf. *C. A.* **24**, 3189.—From vapor pressure and x-ray measurements hydrated GeO_2 is found not to exist. GeO_2 m. 1115 ± 3°. The prepn. of GeO_2 from $Ge(OEt)_2$, of Ge_2OCl_6 and of $Ge(SO_4)_2GeO_2$ is described. V. F. H.

Nitrogen compounds of germanium. I. The preparation and properties of ger-

manic nitride. WARREN C. JOHNSON. *J. Am. Chem. Soc.* **52**, 5160–5(1930).—Ge was heated in NH_3 at 650° to 700°, yielding Ge_3N_4, a light brown powder. The Ge_3N_4 is reduced by H_2 at 700°, reacts with O_2 at 850° and with Cl_2 at 600° to 700°; decomposes at 900° to 1000° and resembles the corresponding compd. of Si in its high stability. GERALD M. PETTY

Studies on heteropoly acids of germanium. I. Germanomolybdic acid. CHARLES G. GROSSCUP. *J. Am. Chem. Soc.* **52**, 5154–60(1930).—A heteropoly acid of Ge and Mo having the formula $H_8[Ge(Mo_7O_7)_6]aq.$ was prepd. The coeff. for "aq." has an apparent max. of 26. The use of MoO_3 for the colorimetric detn. of Ge is suggested. GERALD M. PETTY

Chlorogermanites of alkaloids and chlorogermanites of cesium. ARAKEL TCHAKIRIAN. *Compt. rend.* **192**, 233–4(1931).—$GeCl_2$ forms with alkaloids, as quinine and pilocarpine, salts of 2 types: $GeCl_2$, A.2HCl (dibasic alkaloid) and $GeCl_2$, A.HCl (monobasic alkaloid) in which A represents the mol. of the alkaloid. The method for the prepn. of the salts and their properties are described. If to a soln. of $GeCl_2$ strongly acidified with HCl, a soln. of CsCl is added, a sparsely sol. white microcryst. ppt. is obtained. Its formula is $GeCl_2$ CsCl. An analog is obtained with RbCl, but not with LiCl, NaCl or KCl. At 100° in an atm. of dry HCl the Cs salt liberates the $GeCl_2$. The stability of the new compd. is such that at the temp. of fusion in an atm. of dry HCl $GeCl_2$ is not liberated, but $GeHCl_3$ is formed instead. It is possible, therefore, that the Ge exerts its tri-coördinated valence and that the formula of the compd. is $[GeCl_3]Cs$ B. S. LEVINE

Sulfides of the rare earths. W. KLEMM, K. MEISEL AND H. U. v. VOGEL. *Z. anorg. allgem. Chem.* **190**, 123–44(1930).—The disulfides of La and Ce, and the sesquisulfides of Sc, Yt, La, Ce, Pr, Nd, Sm, Gd, Dy, Er and Yb were prepd. by treating the anhyd. sulfates or chlorides in a stream of dry H_2S at elevated temps. The ds., colors, magnetic susceptibilities and x-ray cryst. structures were studied. On the basis of the color and x-ray detns. the sesquisulfides may be divided into 2 series, the first of which (La-Dy) shows a regular variation in the mol. vol., while the second (Dy-Yb, Yt, Sc) has an irregular variation. The magnetic properties indicate that the sesquisulfides are salts. The disulfides were proved to be of a polysulfide nature. L. L. QUILL

The sulfates of zirconium and hafnium. GEORG v. HEVESY AND ERIKA CREMER. *Z. anorg. allgem. Chem.* **195**, 339–44(1931).—$Zr(SO_4)_2$ and $Hf(SO_4)_2$, prepd. from the tetrahalides or the oxides, always contain an excess of H_2SO_4. This is the reason why the at. wts. of Zr and Hf, as detd. by the sulfate method, are too small. The last traces of H_2SO_4 are removed only at temps. at which the sulfates decomp. noticeably. The relation between the decompn. pressure of the sulfates and the temp. was detd. between 550° and 650°. $Zr(SO_4)_2$ has the higher decompn. pressure. L. K.

Properties of cuprous oxide. O. v. AUWERS. *Naturwissenschaften* **19**, 133–4(1931).—The sp. resistance of artificial Cu_2O depends on various factors, such as the pressure of the surrounding gas: a decrease in air or H_2 pressure gives a decreasing resistance, a decrease in O_2 pressure causes an increase in resistance, while N_2 or Ne has no effect. The resistance is increased several hundred % by increased gas removal from the substance in high vacuum. Cu_2O has a reversible transition point at 56°, above which the previously transparent substance becomes opaque. This transition point is less distinct after removal of gas; O_2 addn. causes a reappearance of it. The thermal expansion coeff. of Cu_2O depends likewise on the condition of the Cu_2O lattice. Fresh Cu_2O has practically no expansion up to 56° (α = 0.00000005), while above 56° it contracts. On cooling it contracts more until 56° is reached, the length changing irreversibly. If previously the gas has been extd. *in vacuo* the coeff. is 0.000001, changing little at 56°. It is concluded that the phys. properties of Cu_2O depend largely on substances dissolved in (O_2) or adsorbed on (H_2) the lattice. For the change in transparency, formation of CuO + Cu is believed to be responsible, although the reversibility remains unexplained. The photo effect of Cu_2O can also be related to the gases moving about in the lattice by the theory of phosphoric centers. Other oxides, as those of Ni, Sn and Zn (Skaupy, *C. A.* **14**, 2111), seem to have similar qualities. B. J. C. VAN DER HOEVEN

Structure of silicates. W. L. BRAGG. *J. Soc. Glass Tech.* **14**, 295–305(1930).—See *C. A.* **24**, 5553. H. F. KRIEGE

Structural principles of compounds of boron and hydrogen. E. WIBERG. *Z. anorg. allgem. Chem.* **187**, 362–8(1930); cf. *C. A.* **23**, 2897.—Polemical against Hellriegel (*C. A.* **24**, 2649). The conception of a special "B linking" to explain the existence of the different B hydrides is unnecessary. From its position in the periodic table it is reasonable to regard B as quinquevalent toward H. As proof that Grimm's hydride

law may be applied to B the similarity between the properties of diborane, B_2H_6, and C_2H_4 is pointed out. This indicates that B is quinquevalent in this compd., the 2 B atoms being joined by a double linking. B. C. A.

Preparation of anhydrous stannous chloride. HENRY STEPHEN. *J. Chem. Soc.* 1930, 2786–7. $SnCl_2$ (long needles) may be more simply prepd. than as previously described (*C. A.* 19, 3261) by treating $SnCl_2.2H_2O$ (1 mol.) with Ac_2O (2 mols.), washing the anhyd. salt, sepg. with dry Et_2O until free from AcOH, and crystg. from AcOH contg. a little Ac_2O. J. BALOZIAN

Preparation and purification of the triiodides of antimony and arsenic for use in immersion media of high refractive index. H. G. FISK. *Am. Mineral.* 15, 263–66 (1930). SbI_3 and AsI_3 were synthesized by gently heating a mixt. of the metals with I in a large test tube. The crude iodides were purified by recrystn. from CS_2. In this step a small excess of the metals was necessary for combination with free I in the soln. A second recrystn. was made further to purify the compds. In prepg. melts from the iodides and piperine it was found essential to avoid heating the mixts. above 135° to prevent decompn. A. M. BRANT

Nitrogen triiodide. HERBERT W. CREMER AND DONALD R. DUNCAN. *J. Chem. Soc.* 1930, 2750–4.—It has been found that NI_3 is formed by the action of NH_3 on the less stable alkali dibromoiodides (*i. e.*, those with high dissocn. pressures). With the K salt as typical, the reaction is: $3KIBr_2 + 4NH_3 = 3KBr + 3NH_4Br + NI_3$, the mechanism of which most probably is: $3KIBr_2 \rightleftharpoons 3KBr + 3IBr$; $3IBr + NH_3 = 3HBr + NI_3$; $3HBr + 3NH_3 = 3NH_4Br$. As found by Dobbin and Masson (*Ibid* 49, 848(1886); *J. prakt. Chem.* 31, 37(1885)), the more stable dibromoiodides such as the tetramethylammonium and trimethylsulfonium salts (having very low dissocn. pressures) do not react with NH_3 to form NI_3, but form additive compds. with 2 mols. of NH_3. J. BALOZIAN

A comparison of the action of halogen salts of iron on phenyl magnesium bromide and phenyl zinc chloride. G. CHAMPETIER. *Bull. soc. chim.* [4], 47, 1131–7(1930).—Anhyd. halogen salts of Fe did not give stable organometallic compds. on reacting with PhMgBr. The 3 reactions obtained were: (1) $6C_6H_5MgBr + 2FeCl_3 \longrightarrow 3(C_6H_5)_2 + 2Fe + 3MgBr_2 + 3MgCl_2$. (2) $2C_6H_5MgBr + 2FeCl_3 \longrightarrow (C_6H_5)_2 + 2FeCl_2 + MgBr_2 + MgCl_2$. (3) $2C_6H_5MgBr + FeCl_3 \longrightarrow (C_6H_5)_2 + Fe + MgBr_2 + MgCl_2$. *PhFeI*, a new organometallic compd., was prepd. according to the reaction $2C_6H_5ZnCl + 2FeI_2 \longrightarrow 2C_6H_5FeI + ZnCl_2 + ZnI_2$. On hydrolysis, the reaction was $2C_6H_5FeI + 2H_2O \longrightarrow 2C_6H_6 + Fe(OH)_2 + FeI_2$. GERALD M. PETTY

The action of halogens on ethyldiiodostibine. Antimony bromodiiodide. ROBERT E. D. CLARK. *J. Chem. Soc.* 1930, 2737–9.—The action of I, Br and Cl on ethyliodostibine (I) is studied. SbI_3 (1.2 g., red needles, m. 168–170.5°) may be prepd. by adding a soln. of I (1.2 g.) in $CHCl_3$ (10 cc.) by drops to I (0.75 g.) in a min. of $CHCl_3$, refluxing for a few min. and cooling, the SbI_3 sepg. out. *Antimony bromodiiodide*, $SbBrI_2$ (long yellow needles (2.9 g.), m. 88°) is formed when Br (1.6 cc. dissolved in $CHCl_3$ (5 cc.)) is added in drops to a soln. of I (12.0 g.) in a min. of $CHCl_3$ (about 15 cc.), cooled in a freezing mixt., refluxed for a few min., cooled to 0°, the $CHCl_3$ decanted off, the mixt. treated with xylene until free from I, and the residue recrystd from $CHCl_3$ or light petroleum (b. p. 80–100°). As typical of the reaction between Cl and I, into a soln. of I (10.0 g.) in warm $CHCl_3$ (10–15 cc.), Cl_2 (530 cc. in all; calcd. 600 cc.) is passed at the max. rate (in this case 35 cc. per min.), at which absorption is complete for the temp. employed (25–30°); the mixt. is boiled, filtered and cooled. red SbI_3 and its yellow metastable modification alone being produced. J. BALOZIAN

Chloramine, its preparations, properties and uses. W. HIRSCHKIND. *Western Construction News* 5, 531–2(1930); *U. S. Pub. Health Eng. Abstracts* 11, W, 21(Feb. 21, 1931).—The chemistry, properties and application to water sterilization of the chloramines (NH_2Cl, $NHCl_2$ and NCl_3) are discussed. C. R. FELLERS

A note on the preparation of hydriodic acid. T. H. WHITEHEAD. *J. Chem. Education* 8, 541–2(1931).—In the prepn. of HI from H_2S and I_2 it has been found that the formation of I_2 on distg. the HI soln. can be prevented if the mixt. is dialyzed through a collodion membrane for 48 hrs. This removes the colloidal S which seems to cause oxidation of the HI. R. H. CARTER

The action of bases on non-metals. A. LAURENCE CURL. *J. Chem. Education* 8, 490–7(1931).—Most of the non-metallic elements with the exception of N and the rare gases react with the alkali hydroxides. In general the reactions take place in accordance with the type $Cl_2 + 2NaOH \longrightarrow NaCl + NaClO + H_2O$. The exact mechanism of this type of reaction is not known or discussed. Similar reactions are obtained with the alkali amides which are analogous to the hydroxides in the NH_3

system of compds. In NH_3 the polysulfides, polyphosphides, etc., are more stable than in water, but the ammono salts are less stable than the corresponding aquo salts.
R. H. CARTER

Course of the reactions between graphite and oxides as well as between heavy metal carbides and oxides. OSKAR MEYER. *Arch. Eisenhüttenw.* **4**, 193–8(1930).—These reactions were studied by detg. the course of vapor pressure-temp. curves. In the case of SiO_2 and graphite, the partial pressure of CO (p_{CO}) reaches 20 mm. at 1400°. MnO is reduced by graphite at lower temps., p_{CO} having attained about 130 mm. at 1200°. Curves and similar data are given for argillaceous earth and graphite and reactions between the carbides of Si, Mo, W and Cr and the oxides of Mn, Fe, Cr and Si.
H. STOERTZ

The interaction between iodine pentoxide and nitric oxide. MADHAVLAL SUKHLAL SHAH AND TRAMBAKLAL MOHANLAL OZA. *J. Chem. Soc.* 1931, 32–6.—The course of the reaction at 120° between I_2O_5 and NO was followed by measuring (*a*) the vol. of NO used, (*b*) the amt. of I_2 produced, and (*c*) the amt. of nitrate formed. The reaction may take place according to either (I) $10NO + 2I_2O_5 = 2I_2 + 5N_2O_4$, and subsequently $5N_2O_4 + I_2O_5 = I_2 + 5N_2O_5$, or (II) $10NO + 3I_2O_5 = 3I_2 + 5N_2O_5$. No decisive evidence could be obtained to indicate that it occurred according to I. The assumption that first II takes place with the formation of N_2O_5, and subsequently N_2O_4 is formed according to $5N_2O_5 + 5NO = 7.5N_2O_4$ is equally possible. J. B.

Action of mercuric oxide on solutions of cupric chloride. H. PÉLABON AND MLLE. DELWAULLE. *Bull. soc. chim.* [4], **47**, 556–9(1930); cf. *C. A.* **19**, 1105; **24**, 3454.—The reaction between HgO and $CuCl_2$ is shown to take place according to $3HgO + 4CuCl_2 = 3HgCl_2 + 3CuO.CuCl_2$. The action of CuO on, as well as the soly. of $HgCl_2$ in, solns. of $CuCl_2$ was studied separately.
G. TOENNIES

Formation of a ferromagnetic iron sesquioxide by decomposition of the hydrate of van Bemmelen's sesquioxide. G. CHAUDRON AND A. GIRARD. *Compt. rend.* **192**, 97–9(1931).—The cryst. Fe_2O_3 H_2O prepd. from $Fe_2O_3.Na_2O$ by the method of van Bemmelen (*J. prakt Chem.* **46**, 520(1892)) loses water slowly at 100° and rapidly at 140° to form a strongly magnetic sesquioxide which at 675° is converted into the ordinary sesquioxide. Both the monohydrate and the oxide are hexagonal, while the magnetic oxide obtained by slow oxidation of magnetite (Malaguti's oxide) is cubical (cf. Welo and Baudisch, *C. A.* **19**, 3182).
K. V. THIMANN

Decomposition of magnesium salts by calcium carbonate at elevated temperatures. E. SAUER AND J. HUTER. *Z. anorg. allgem. Chem.* **195**, 241–6(1931).—$MgCl_2$, $MgSO_4$ and $Ca(HCO_3)_2$ in aq. soln. were autoclaved for long periods (as high as 9 hrs.); the courses of the decompns. were followed. Mixts. of the Mg salts with $Ca(HCO_3)_2$ were also studied; pptn. of $Mg(OH)_2$ occurs. Solid $CaCO_3$ was also present in some expts. Data and curves are given.
WILLIAM E. VAUGHAN

The double decomposition between aqueous sodium formate and ammonium sulfate. G. BREDIG AND F. LOTZ. *Chem.-Ztg.* **55**, 4(1931).—Isotherms are given for the reciprocal salt pair at 13.5°, 24.6° and 60°. There are several difficulties in the way of prepg. HCO_2NH_4 by double decompn.
T. H. CHILTON

Thoryl nitrate. ED. CHAUVENET AND MME. SOUTEYRAND-FRANCK. *Bull. soc. chim.* [4], **47**, 1128–31(1930).—$Th(NO_3)_4.5H_2O$ was obtained by slow evapn. of a soln. in air at 15°. Above 80° the trihydrate was obtained; above 110° the dihydrate; from 125° to 150° decompn. of the salt yielded $ThO(NO_3)_2.1/2H_2O$; from 150° to 360° decompn. was continuous, yielding pure ThO_2. The dihydrate was not affected by reduced pressure. Anhyd. $Th(NO_3)_4$ could not be obtained. $Th(NO_3)_4.5H_2O$ reacted in soln. with 2 mols. NaOH, yielding $ThO(NO_3)_2.H_2O$. No other product of hydrolysis was obtained. The hydrolysis is similar to that of $ZrCl_4$ (cf. *C. A.* **24**, 5654).
GERALD M. PETTY

The complex cuprothiosulfates of ammonium, potassium and sodium. III. G. SPACU AND I. G. MURGULESCU. *Bul. soc. stiinte Cluj* **5**, 344–70(1930); cf. *C. A.* **24**, 4230.—Potentiometric titrations of $Cu(NO_3)_2$ by $Na_2S_2O_3$ in the presence of regulated amts. of EtOH show flexures corresponding to the following Na cuprothiosulfates: $Na_3Cu_7(S_2O_3)_6.8H_2O$, $NaCuS_2O_3.1\,1/2H_2O$, $Na_4Cu_2(S_2O_3)_3.xH_2O$, $Na_5Cu(S_2O_3)_3.xH_2O$, $Na_3Cu(S_2O_3)_2.2NaNO_3$. $Na_3Cu_7(S_2O_3)_6.8H_2O$ is formed as a yellow cryst. ppt. when 7 vols. of 0.5 *M* $Cu(NO_3)_2$ and 13 vols. of 0.5 *M* $Na_2S_2O_3$ are mixed in the presence of 3 1/2 vols. of EtOH. $NaCuS_2O_3.1\,1/2H_2O$ is obtained as a white amorphous ppt. when 5 vols. of 0.2 *M* $Cu(NO_3)_2$ are mixed with 4 vols. of 0.5 *M* $Na_2S_2O_3$ in the presence of 16–20 vols. of EtOH. When 2 moles of $NaCuS_2O_3.1\,1/2H_2O$ are titrated with 1 mole of $Na_2S_2O_3$, $Na_4Cu_2(S_2O_3)_3$ seems to be produced in the form of a brown oily soln. This salt could not be further isolated, for upon evapn. the soln. changed to a glassy homo-

geneous mass. It was attempted to prep. $Na_3Cu(S_2O_3)_2$ from a soln. contg. theoretical amts. of $Na_2S_2O_3$ and $NaCuS_2O_3$. A mass of iridescent crystals was obtained, too hygroscopic for further purification. The double salt $Na_3Cu(S_2O_3)_2.2NaNO_3$ is prepd. by treating a mixt. of $NaCuS_2O_3$ and $NaNO_3$ with 3 *M* $Na_2S_2O_3$. Upon recrystn. it appeared as colorless needles. The following table contrasts the hydration of the cuprothiosulfates of NH_4, K and Na:

		$Na_6Cu_7(S_2O_3)_6.8H_2O$
$NH_4CuS_2O_3.{}^1/_2H_2O$	$KCuS_2O_3.H_2O$	$NaCuS_2O_3.1{}^1/_2H_2O$
$(NH_4)_4Cu_2(S_2O_3)_3.2H_2O$	$K_4Cu_2(S_2O_3)_3.2H_2O$	$Na_4Cu_2(S_2O_3)_3.xH_2O$
	$K_4Cu_2(S_2O_3)_3.H_2O$	?
$(NH_4)_6Cu(S_2O_3)_3.4H_2O$	$K_6Cu(S_2O_3)_3.3H_2O$	$Na_6Cu(S_2O_3)_3.xH_2O$

J. H. REEDY

A series of new tetrammine-cobaltic complexes. PULIN BIHARI SARKAR AND TUHINANGSU DAS-GUPTA. *J. Indian Chem. Soc.* 7, 835–7(1930).—$\left[Co^{Cl}_{(NH_3)_5}\right]S_2O_3$ at 35–40° for 4 weeks changes completely to the more stable $\left[Co^{S_2O_3}_{(NH_3)_5}\right]Cl$ without appreciable change in wt. Thiosulfato-pentammine compds. possess a characteristic ultra-violet absorption spectrum by which they can be easily distinguished from their ionic isomers. Their conductivities are half that of the corresponding chloro compd. $\left[Co^{(1,6)Cl_2}_{(NH_3)_4}\right]Cl$ or $\left[\begin{matrix}(1)Cl\\ Co(2)H_2O\\ (NH_3)_4\end{matrix}\right]Cl_2$ in aq. soln. with $Na_2S_2O_3$ below 0° gives *trans-thiosulfato-aquo-tetrammine-cobaltic thiosulfate* $\left[\begin{matrix}(1)S_2O_3Co(NH_3)_4\\ (6)H_2O\end{matrix}\right]_2S_2O_3$ (I) by double decompn. The free S_2O_3 group of I is replaced to give the corresponding Cl, Br, NO_3, SCN, CrO_4, SO_4 and S_2O_6 compds. Their ultra-violet absorption spectra in aq. solns. are identical. At higher temps. the soln. by hydrolysis gives, $\left[\begin{matrix}(1)S_2O_3Co(NH_3)_4\\ (6)OH\end{matrix}\right]$. Further hydrolysis permits the formation of H_2SO_3, which partially reduces the Co^{+++} compds. to the Co^{++} - Co^{+++} complex, $\left[\begin{matrix}(H_2O)_2\\ Co''(OH)_2[Co'''(NH_3)_4]_2\end{matrix}\right](S_2O_3)_2$, isolated by alc. FOSTER DEE SNELL

A new class of ammines. The double selenocyanammines. G. SPACU AND V ARMEANU. *Bul. soc. stiinte Cluj* 5, 294–318(1930).—Solns. of $K_2Hg(SeCN)_4$ and $KAg(SeCN)_2$ were formed by the action of KSeCN on $HgCl_2$ and AgCl, resp. By causing these solns. to react with various metallic salts of ethylenediammine, the following double selenocyanammines were pptd.: $Cu(en)_2[Hg(SeCN)_4]$, $Ni(en)_2[Hg(SeCN)_4]$, $Cd(en)_2[Hg(SeCN)_4]$, $Zn(en)_2[Hg(SeCN)_4]$, $Co(en)_2[Hg(SeCN)_3]_2(SeCN)$, $Cu(en)_2[Ag(SeCN)_2]_2$, $Ni(en)_2[Ag(SeCN)_2]_2$, $Cd(en)_2[Ag(SeCN)_2]_2$, $Zn(en)_2[Ag(SeCN)_2]_2$, $Co(en)_3[Ag(SeCN)_2]_3$. These double selenocyanammines, as a class, are cryst. solids, stable toward light and dry air. They are insol. in EtOH, Et_2O, C_6H_6, $CHCl_3$, etc., and slightly sol. in H_2O, Me_2CO, etc. They are decompd. by the feeblest acids and bases. J. H. REEDY

The salts of hexafluophosphoric acid. WILLI LANGE AND EMIL MÜLLER. *Ber.* 63B, 1058–70(1930).—The reaction of dil. HF with P_2O_5 gives three types of acids H_2PO_2F, HPO_2F_2 and HPF_6. HPO_2F_2 and HPF_6 ppt. with nitron. Keeping the soln overnight results in complete hydrolysis of HPO_2F_2 and the soln. yields with nitron a ppt. of pure nitron-HPF_6. This ppt. shaken with chloroform and ammonia gives the well-crystallizing NH_4PF_6 in the water soln. The hexafluophosphates strikingly resemble the perchlorates in soly. They differ completely, however, in crystal form All the inorg., especially the complex, PF_6 compds. have refractive indexes similar to that of water, which gives them a gel-like appearance in water suspension. Aryl diazonium-PF_6 compds. are less sol. than the perchlorates; they do not decompose when dry, and are not sensitive to shock or blows. Heating results in decompn. according to: $ArN_2PF_6 = ArF + PF_5 + N_2$. HPF_6 is stable in cold soln. but is hydrolyzed in hot soln. PF_6 compds. on boiling with strong acids are hydrolyzed. Mol vols. of PF_6 and ClO_4 compds. are compared. Prepn. and properties are described for KPF_6, NH_4PF_6, $NaPF_6.H_2O$, $RbPF_6$, $CsPF_6$, $Cu(PF_6)_2.5NH_3.H_2O$, $Cu(PF_6)_2.4NH_3$, $Cu(PF_6)_2$ $2C_2H_4(NH_2)_2.2H_2O$, $Cu(PF_6)_2$ $5C_5H_5N.NH_3.H_2O$, $Co(PF_6)_2.6NH_3$, $Ni(PF_6)_2$ $6NH_3$, Me_4NPF_6, Et_4NPF_6, PhN_2PF_6, *o*-$MeC_6H_4N_2PF_6$, *p,p'*-$F_6PN:NC_6H_4C_6H_4N:NPF_6$, $C_5H_5N.HPF_6$, strychnine-HPF_6, brucine-HPF_6, morphine-HPF_6, cocaine-HPF_6, nitron-HPF_6, nitron-$HAsF_6.H_2O$, nitron-$HSbF_6.2H_2O$ and nitron-$HSbF_6$. R. W. S.

Bis-*p*-phenetyl telluride and its derivatives. GILBERT T. MORGAN AND FRANCIS H. BURSTALL. *J. Chem. Soc.* **1930**, 2599–601.—Bis-*p*-phenetyl telluride and some of its derivs. are prepd., the view of Burstall and Sugden (*C. A.* **24**, 2652) that bis-*p*-phenetyl telluridichloride is a nuclear-substituted telluride being confirmed. *Bis-p-phenetyl telluride*, $(EtO.C_6H_4)_2Te$, (white plates, m. 64°) is prepd. by adding 63 g. *p*-bromophenetole (by the Sandmeyer reaction from *p*-phenetidine) to Mg (7.2 g.) suspended in dry Et_2O, warming until nearly all the Mg is in soln., decanting, adding the soln. slowly to a $TeBr_2$ (43 g.) suspension in dry Et_2O, refluxing for several hrs., cooling, treating with ice, adding HBr, filtering, drying the Et_2O layer over $CaCl_2$, evapg. to dryness, extg. the residue of gum with petroleum ether (b. 40–60°), evapg. and repeatedly recrystg. the solid sepg. out from alc. *Bis-p-phenetyl telluridichloride*, $(EtO.C_6H_3Cl)_2Te$, m. 108°, is prepd. (1) by adding Cl_2 to a soln. of the preceding telluride in CCl_4, (2) by heating *p*-phenetyl telluritrichloride with an excess of phenetole at 180–190° and (3) by heating $TeCl_4$ (1 mol.) with phenetole (4 mols.) at 180–190°.

Bis-p-phentyl tellurioxychloride, $(EtO.C_6H_4)_2Te\langle{}^{O}_{Cl\ Cl}\rangle Te(C_6H_4\ OEt)_2$ (fluffy white crystals, decompg. at 193°) is prepd. by boiling an aq. suspension of the dichloride. *Bis-p-phenetyl telluridibromide*, $(EtO.C_6H_3Br)_2Te$, (lemon-yellow crystals, m. 127°) and *bis-p-phenetyl telluridiiodide*, $(EtO.C_6H_3I)_2Te$, (orange-red needles, m. 144°) are prepd. from mixts. of their generators in soln. *Bis-p-phenetyl telluroxide*, $(EtO.C_6H_4)_2TeO$, (white microcrystals, decompg. at 181°) is prepd. by boiling the dichloride or the dibromide with aq. 2 *N* NaOH soln. *p-Anisyl-p-phenetyl telluridichloride* (white needles, m. 165–6°) is prepd. by heating the trichloride (1 mol.) at 160° with anisole (4 mols.) for 6 hrs., cooling, treating with petroleum ether (b. 40–60°) and recrystg. the residue repeatedly from alc. *p-Anisyl p-phenetyl telluride* (white needles, melting to a clear liquid at 45°) is prepd. by heating the dichloride for an hr. in glacial AcOH with Zn dust in excess, filtering, pouring the filtrate into H_2O and crystg. the ppt. from alc.

J. BALOZIAN

Researches on residual affinity and coördination. XXXII. Complex salts of bivalent silver. GILBERT T. MORGAN AND FRANCIS H. BURSTALL. *J. Chem. Soc.* **1930**, 2594–8; cf. *C. A.* **23**, 1877.—As with Cu salts and a diamine (*C. A.* **20**, 3400, 3401; **21**, 3166), it has been found that the chelate group in α,α'-dipyridyl is sufficiently powerful to stabilize a bivalent argentic complex. Thus, by starting with α,α'-dipyridyl (as prepd. by Hein and Retter (*C. A.* **23**, 143)), a series of Ag salts is prepd. in which the bivalent Ag has coördination nos. of both 4 and 6. *Bis-α,α'-dipyridylargentous nitrate* $[Ag2dipy]NO_3$, (felted masses of yellow needles, decompg. at 155°) is prepd. from hot alc. solns. of $AgNO_3$ (16.9 g.) and α,α'-dipyridyl (31.2 g.), and recrystd. from hot dil. alc. *Bis-α,α'-dipyridylargentic persulfate*, $[Ag2dipy]^{II}S_2O_8$, (deep reddish brown microcrystals, decompg. rapidly at 137°) is prepd. by stirring the preceding nitrate into a cold satd. soln. contg. an excess of $K_2S_2O_8$. *Pentakis-α,α'-dipyridyldiargentic persulfate*, $[Ag_25dipy](S_2O_8)_2$, (small reddish purple needles, decompg. rapidly at 159°) is prepd. by triturating the preceding persulfate with cold dil. HNO_3 (60% HNO_3 (d = 1.4) and 40% H_2O) and pptg. with H_2O (4 vols.). *Tris-α,α'-dipyridylargentic nitrate*, $[Ag3dipy]^{II}(NO_3)_2$, (small dark brown needles, decompg. at 176°) is obtained by draining the residue from the persulfate trituration, extg. with warm H_2O, adding an excess of aq. NH_4NO_3 and cooling in ice. *Tris-α,α'-dipyridylargentic chlorate*, $[Ag3dipy]^{II}(ClO_3)_2$, (dark purple plates or needles, decompg. quietly at 171°) is prepd. by adding aq. $NaClO_3$ to the preceding nitrate and recrystg. the product from H_2O by the addn. of $NaClO_3$. *Tris-α,α'-dipyridylargentic perchlorate*, $[Ag3dipy]^{II}(ClO_4)_2$, (orange-brown microcrystals, detonating violently on heating) is prepd. by adding $NaClO_4$ to a soln. of either the preceding chlorate or nitrate. *Bis-α,α'-dipyridylargentic hydrogen sulfate*, $[Ag2dipy]^{II}(HSO_4)_2$, (brown cryst. powder, decompg. at 157°) is prepd. by treating the persulfate with cold 40% H_2SO_4 or by adding Na_2SO_4 and H_2SO_4 to solns. of the preceding chlorate or nitrate.

J. BALOZIAN

7—ANALYTICAL CHEMISTRY

W. T. HALL

Reply to the remarks of L. Moser and L. v. Zombory concerning my paper on "New ways in analytical chemistry." J. DICK. *Z. anal. Chem.* **83**, 105–7(1931); cf. *C. A.* **25**, 891; M. and Z., *C. A.* **24**, 4725.—The method of washing the ppt. with alc. and ether with vacuum drying at room temp. is defended. W. T. H.

Collecting average samples from storage tanks. H. O. BERNSTROM. *Chemist Analyst* **20**, No. 2, 10–1(1931).—The taking of a sample from tank cars by means of a circular "thief" is described. W. T. H.

Standardizing silver nitrate solutions. ALVIN MAYHAN. *Chemist Analyst* **20**, No. 2, 14 5(1931).—One soln. of $AgNO_3$ can be standardized against another of the same kind by making an approx. 0.24 *N* HCl soln. and titrating one portion with the old and another portion with the new soln. by Mohr's method. W. T. H.

Sodium sulfite for analysis. HOLZVERKOHLUNGS-IND. A.-G. *Chem.-Ztg.* **54**, 502(1930).—Contrary to earlier statements, pure Na_2SO_3 does not yield alk. solns., and the faint blue color with thymolphthalein is destroyed by one drop of 0.1 *N* HCl. In the use of Na_2SO_3 for the detn. of CH_2O, the grade "pro analysi" is not essential, because reasonable proportions of neutral saline impurities, such as Na_2SO_4, do not affect the titration; Na_2CO_3 must, however, be absent. B. C. A.

"Direct green B." A new reagent very sensitive to copper. P. SISLEY AND DAVID. *Bull. soc. chim.* [4], **47**, 1188-92(1930).—When Cu salts are added at 90° to a soln. of "direct green B," the color changes from blue-green to violet-pink. soln. should have a p_H value between 6 and 9. The ratio dye/Cu should be 10, but results are satisfactory between 6 and 50. The reaction is sensitive to 0.1 mg. Cu per l. Anions had no effect on the color. No other metal gave a violet-pink col Neutral salts retarded the reaction and reduced the intensity of the color, K_2SO_4 having the greatest effect. Colloids masked the reaction. Cu was found in distd. water used for diluting serums and medicines. GERALD M. PETTY

Correct methods of analyzing for carbon in rustless steels. C. M. JOHNSON. *Iron Age* **127**, 549–51(1931).—In some cases it is necessary to have the results on C detns. accurate to 0.01% of the wt. of the sample. Low results may be caused by incomplete combustion because of failure to cover the sample with Pb_3O_4, and high results may be caused by the S content. Directions are given for carrying out the combustion in an elec. furnace, and an absorption train is shown in which danger due to SO_2 or SO_3 fumes is overcome by passing the gas through 50 ml. of 5% $KMnO_4$ soln., through the usual Zn tower, through P_2O_5 and finally into the Stetser and Norton ascarite bulb. W. T. H.

Determination of total sulfur by the sodium peroxide method. M. R. BERCOVITCH. *Chemist Analyst* **20**, No. 2, 8(1931).—In neutralizing the aq. ext. of the melt, loss by effervescence can be avoided by introducing the acid at the bottom of the soln. by means of a pipet or funnel drawn out to a fine point. W. T. H.

Wet oxidation method for the determination of total sulfur in slags, ores, cinders, etc. FRANK W. SCOTT. *Chemist Analyst* **20**, No. 2, 8(1931).—The sample is dissolved in concd. HNO_3 which has been satd. with $KClO_3$, and the resulting SO_4^{--} is detd. as in the well-known Lunge method. W. T. H.

Detection of minute quantities of phosphorus in oil. CONRAD STICH. *Pharm. Ztg.* **76**, 112(1931).—A commentary on S.'s previously published method (*C. A.* **21**, 3856) with suggestions for its more precise application. W. O. E.

Spectrophotometric determination of phosphorus. TORSTEN TEORELL. *Biochem. Z.* **230**, 1-9(1931).—Fiske-Subbarow's procedure for the colorimetric detn. of P is modified to be used for a photospectrometric analysis of quantities ranging from 0.01 to 0.05 mg. P. The method dispenses entirely with the standard soln., and detns. can be made with an accuracy of ±2%. S. MORGULIS

Colorimetric estimation of nitrogen by direct nesslerization, with a note on a modified Nessler-Folin reagent. LANCE S. WALTERS. *Australian J. Exptl. Biol. Med. Sci.* **7**, 113–6(1931).—By using a gum ghatti soln. for protective colloid and replacing NaOH by LiOH in the Nessler-Folin soln., it was possible to nesslerize 100 cc. of soln. contg. 2 cc. concd. H_2SO_4 and up to 1 mg. N. The nesslerized soln. remained clear for weeks. The usual Kjeldahl digest contg. 20 cc. of H_2SO_4 is diluted to 100 cc. and an aliquot taken which contains 0.5 to 1.0 mg. N. This is diluted to about 60 cc., 3 cc. colloid soln. is added, followed by nesslerization and making up to 100 cc. for matching a standard. The protective colloid soln. contains 2% of alc.-pptd. and dried gum in thymol-satd. water. C. G. KING

Determination of nitrogen by a "micro-Kjeldahl" method. A. C. ANDERSEN AND B. NORMAN JENSEN. *Z. anal. Chem.* **83**, 114–20(1931).—The method previously described by A. and J. (*C. A.* **19**, 1461) can be used equally well for 0.5–1 mg. of N if the app. is built on a smaller scale. Such a modification is shown and exact dimensions are given. The app. was tested with 5 org. nitrogenous compds. and excellent results were obtained. W. T. H.

Determination of some gases by means of the spectrograph. BOUCHETAL DE LA

ROCHE. *Bull. soc. chim.* [4], **47**, 1326–31(1930); cf. *C. A.* **24**, 1252, 1580, 5667.—Further description of the method is given. Spectrographic analyses of mixts. of Si and B fluorides and Cl with dry air are in close agreement with the results by the chem. method. Br and I are less sensitive and therefore difficult to det. by this method. O gives certain lines by which it can be detd., but the intensity is independent of the quantity of O introduced; this is probably due to the oxidation of the electrodes. N diluted with H or CO_2 is detd. by the line 5008 or 3437, resp., and the results agree well with those of volumetric analysis. H. W. WALKER

Bromoiodometric investigations. V. Determination of bromine in bromides. J. H. VAN DER MEULEN. *Chem. Weekblad* **28**, 82-6(1931); cf. *C. A.* **25**, 1182.—To 20 cc. KBr soln. (contg. about 0.1 g.) add 10 cc. *N* KOCl in 0.1 *N* KOH and 25 cc. satd. NaCl soln. Heat the mixt. on the water bath to about 85° and add 10 cc. of a satd. H_3BO_3 soln. Continue the heating for about 5 min. after discoloration takes place. Decompose the excess KOCl with 10 cc. *N* H_2O_2 and boil off the excess H_2O_2. After cooling add KI and HCl and titrate the mixt. A blank titration is necessary. E. SCHOTTE

Spectroscopic detection of fluorine. JACOB PAPISH, L. E. HOAG AND W. E. SNEE. *Ind. Eng. Chem., Anal. Ed.* **2**, 263–4(1930).—A mixt. of a substance contg. F with a salt of Ca is placed on a graphite electrode and the arc or spark spectrum photographed. A band at 5291 A. U. is intense enough to detect 0.02 mg. F. The method is applied to complex F compds., F minerals, bones and teeth of animals. In the latter case and when the quantity of F is very small, the sample is concd. by distg. with H_2SO_4 and the HF is collected in $Ca(OH)_2$ soln. The dried CaF_2 is then applied to the electrodes. G. M. MURPHY

Qualitative microanalysis. Detection of traces of copper by capillary separation. F. FEIGL AND H. J. KAPULITZAS. *Mikrochemie* [N. S.], **2**, 239–44(1930).—Traces of Cu may be detected in the presence of large amts. of Ni by placing one drop of the AcOH soln. of the elements on a filter paper which has been dipped into an alc. soln. of dithioöxamide and dried. If Cu is present, the middle of the drop immediately develops an olive-green to black ring; the Ni diffuses further before it reacts with the amide, so that a white ring surrounds the Cu ring and is itself surrounded by a dirty violet to violet-blue ring. The reaction will detect 0.05γ of Cu in the presence of 20,000 times as much Ni or 2000 times as much Co, which forms a yellowish brown ring outside the Cu ring. B. C. A.

Effect of the presence of other elements on some microscopical tests for the metals. W. F. WHITMORE AND F. SCHNEIDER. *Mikrochemie* [N. S.], **2**, 293–304(1930).—The formation of triple nitrates with K and Pb is a test for Cu or Ni in the absence of the other, the former giving black or dark brown cubes and the latter light yellow cubes; when both elements are present the color may vary from light yellow to black. The oxalate test for Mn, Cd, Pb and bivalent Sn is sp. only when each element is present alone; when 2 or more are present in the test soln the crystals formed usually have a different habit from the normal, or the crystals due to one element may fail to appear. Similarly, the $Hg(CNS)_2$ test for Cu, Co, Zn and Cd does not distinguish the elements from one another when in admixt., the crystal habit and color varying considerably with the nature and relative proportions of the metals present. Fe cannot be detected by the ferrocyanide test when more than 10 times as much Cu is present, and Pb and Hg cannot be detected by the iodide test when 50 times as much Hg or Pb is present in the same soln. (cf. *C. A.* **24**, 2964). B. C. A.

Analysis of white metals and solder. H. L. MATTHIJSEN. *Chem. Weekblad* **27**, 284–7(1930).—Slight modifications in standard methods, and particularly in simultaneous electrolytic detn. of Pb and Cu, are described. B. C. A.

Spot tests for the detection of the precious metals. H. HOLZER. *Mikrochemie* [N. S.], **2**, 271–6(1930).—For the detection of Au in a soln. contg. Pt a drop of the liquid is placed on a filter paper and allowed to dry; on addn. of a min. drop of acid $SnCl_2$ soln. to the middle of the spot it becomes yellowish brown, and a purple ring gradually forms around the outside if Au is present. Feigl's test for Ag with *p*-dimethylaminobenzylidenerhodanine (*C. A.* **22**, 4080) is interfered with by Au, Pt and Pd, which produce colored flocculent ppts. with the reagent. The Pd ppt. is dark violet in color and its formation serves as a sp. test for Pd. B. C. A.

Inorganic gravimetric microanalysis. I. Determination of minute amounts of gold in the presence of much iron, lead and copper. J. DONAU. *Mikrochemie* [N. S.], **2**, 257–63(1930).—To the boiling, slightly acid soln. (0.2–0.3 cc.) of the Au is added a small piece of Japanese silk previously washed in HCl, then in water and dried. The Au deposits rapidly on the silk, coloring it dark purple; a 2nd piece of silk may be added

to make sure that pptn. is complete. The silk is collected on a glass microfilter, washed with hot water, dried in a small Pt-foil dish and ignited over a small flame. Further heating causes the Au residue to alloy with the Pt, which is then weighed on the microbalance. Fe, Cu and Pb do not interfere in the test. B. C. A.

Determination of cadmium with potassium ferrocyanide. ALFRED KUNDERT. *Chemist Analyst* **20**, No. 2, 5–6(1931).—It is shown that the $K_4Fe(CN)_6$ titration gives results that are comparable to those obtained gravimetrically. W. T. H.

Specific reaction for the detection of cadmium. F. PAVELKA AND E. KOLMER. *Mikrochemie* [N. S.], **2**, 277–80(1930).—Cd salts in AcOH soln. yield a characteristic yellowish white cryst. ppt. with nitrophenolarsinic acid; under the microscope the crystals appear as long narrow rectangular prisms often clustered in prickly spherical aggregates. The reaction will detect 1 part of Cd in 200,000 parts of soln. and is not affected by the presence of any metal which forms a sol. acetate. B. C. A.

Detection of zinc by means of resorcinol. K. FABICH. *Verhandl. Geol. Bundesanst. Wien* **1929**.—The addn. of a 10% soln. of resorcinol in alc. to a dil. soln. of a Zn salt gives on shaking in the cold a yellow color, which on heating changes to olive-green or blue, the color depending on the concn. Other metals, such as Cd, Ni, Co, Cu and Mn, give similar colors with resorcinol. B. C. A.

Analysis of the coating of galvanized sheet steel. FRANK W. SCOTT. *Chemist Analyst* **20**, No. 2, 4–5(1931).—Cut 3 test pieces, 2.25 in. sq., of the metal, clean with gasoline or benzene, dry, mark one of them and weigh. Place the 3 pieces in a 400-cc. beaker with their bottom edges resting on pieces of pure Zn and with the sheets sepd. by glass rods. Cover the squares of metal with 3.3 *N* H_2SO_4 and put a watch glass over the beaker. Move the pieces from time to time but keep them in close contact with the pure Zn. When the evolution of gas is very slow, showing that the coating has been dissolved, transfer the acid to another beaker and at once cover the undissolved metal with water. Using a policeman and a jet from the washer bottle, scrub off the sheets and pieces of pure Zn, adding the black residue and water to the acid soln. Dry the marked sheet and again weigh; the loss in wt. in g. is equal to the wt. of coating in oz. on a piece a foot sq. This wt. multiplied by 3 gives the wt. of sample analyzed. Titrate the Fe^{++} in the soln. with $KMnO_4$. Add HNO_3, evap. with concd. H_2SO_4 and det. the Pb as $PbSO_4$. Dil. the filtrate from the $PbSO_4$ to 450 cc. and, while introducing H_2S, reduce the acidity so that some Zn together with all the Cd is pptd. as sulfide. Filter, dissolve in acid and repeat this pptn. twice more until finally pure CdS is obtained and weighed. To det. Sn, treat 3 more pieces in the same way, from the resulting soln. ppt. sulfides of Sn and Pb with H_2S, dissolve the ppt. in aqua regia, boil off Cl_2, dil., nearly neutralize with NH_4OH, add an excess of NH_4OAc, make neutral to methyl orange and allow to stand in a warm place to ppt. $Sn(OH)_2$. Filter, ignite and weigh as SnO_2. Call the remainder of the coating Zn. W. T. H.

Determination of the iron contained in the coating of galvanized steel. BENJAMIN E. COHN. *Chemist Analyst* **20**, No. 2, 4(1931).—The method of obtaining the sample is similar to that described by Scott (see preceding abstr.) but $HgCl_2$ is added to the soln. before titrating with $KMnO_4$. W. T. H.

The determination of iron in aluminum. GIULIO AGAMENNONE. *Giorn. chim. ind. applicata* **12**, 486–7(1930).—Fe occuring in Al is usually detd. volumetrically as Fe^{II}, leading to some losses due to carbides not completely decompd. because of the danger of oxidizing to Fe^{III} again, and to some Fe remaining as Fe^{III}. To avoid these losses, Fe is detd. as Fe^{III} by dissolving the Al in dil. HCl, boiling the soln., adding H_2O_2 and again boiling. The soln. is then cooled and the Fe^{+++} detd. iodometrically. A. W. CONTIERI

New test for tin. IRWIN STONE. *Chemist Analyst* **20**, No. 2, 6–7(1931).—Meissner's Bunsen flame test is described in which a blue coloration is obtained. W. T. H.

Lead-antimony-tin alloys. MAX HALE. *Chemist-Analyst* **20**, No. 2, 10(1931).—The sp. gr. of the sample gives a fair idea of the Sb content of Pb-Sb alloys. The treatment of the alloy with acid, sepn. of Sb and Sn from Pb by NaSH soln., detn. of Pb as $PbSO_4$ in the ppt., electrodeposition of the Sb from the alk. soln. to which KCN is added and the pptn. of Sn in the electrolyzed soln. are described. W. T. H.

Electrolytic determination of copper in steel. LAWRENCE ANDERSON. *Chemist Analyst* **20**, No. 2, 7–8(1931).—Dissolve 5 g. of metal in 100 ml. of 3 *N* H_2SO_4, filter off the Cu and any insol. carbide, treat the residue with hot dil. HNO_3, filter and electrolyze. W. T. H.

Analytical applications of a reaction of copper salts. MANUEL LORA Y TAMAYO. *Rev. acad. ciencias Madrid* [2], **25**, 267–98(1930).—The reaction between Cu^{++} and

tartrate in alk. soln. serves to indicate 15.9–16.7 mg. of Cu^{++} per 100 cc. of aq. soln. or 6.4 mg. of Cu^{++} if sufficient alc. is added. By measuring the vol. of KCN used to decolorize the soln. a fairly satisfactory detn. of Cu^{++} can be made. A bibliography of methods for detg. Cu and of studies of the action of various cations on alk. tartrate is given. JOHN B. ENTRIKIN

Study of Spacu's reaction. Methods for the volumetric determination of copper based on this test. J. GOLSE. *Bull. soc. chim.* **49**, 84–100(1931).—Salts of Cu give ppts. of $[Cu(C_5H_5N)_2](SCN)_2$ when placed in contact with pyridine and an alk. thiocyanate. The ppt. is easily dissolved by $CHCl_3$ giving an emerald-green soln., and by evapn. of this soln. a residue is obtained which can be weighed as such or ignited to CuO. Quantities of Cu varying from 5 to 60 mg. can be detd. volumetrically by using 1 cc. of pyridine and 25 cc. of 0.1 *N* KCNS in a total vol. of 100 cc., filtering off the ppt., adding a known quantity of $AgNO_3$ and titrating the excess Ag^+ with 0.05 *N* NH_4CNS, using ferric alum as indicator. Cl^-, Br^-, Zn, Cd, Ni and Co must be absent and proper allowance must be made for a blank run in the absence of Cu. Another method, suitable for even smaller quantities of Cu, consists in pptg. the Cu similarly, filtering the soln. and detg. the excess CNS by the following method: Take 20 cc. of filtrate, add 0.5 cc. of NaOH (d. 1.32–1.36) and expel excess pyridine by a current of steam, using glass connections without any contact with rubber and keeping the vol. at 20 cc. Cool and dil. to 30 cc. Add 20 cc. NaBrO soln. (5 cc. Br_2, 50 cc of NaOH (d. 1.32–1.36) and water to make 500 cc.) to oxidize the excess CNS^- to SO_4^{--} and CNO^- with reduction of BrO^- to Br^-. After 15 min. add 10 cc. of 20% KI and 20 cc. of 2 *N* HCl. Titrate the liberated I_2 with 0.1 *N* $Na_2S_2O_3$. Run a blank without any Cu soln. W. T. H.

Separation of nickel from cobalt metal or ferro-cobalt. H. A. KAR. *Chemist Analyst* **20**, No 2, 15(1931). Treat the HNO_3 soln. with NH_4OH and $(NH_4)_2S_2O_8$, filter, add considerable NH_4Cl and treat with dimethylglyoxime. Dissolve the ppt. in acid and repeat the above treatment; the final Ni ppt. will be free from Co. W. T. H.

Estimation of copper and nickel in steel. W. L. KNOYLE. *Paper before Swansea Tech Coll. Met. Soc.*, 18 pp.(Feb. 22, 1930); *Metals & Alloys* **1**, 738.—If small amts. of Cu are assocd. with large amts of Fe, the sepn. is best effected by the pptn. of the Cu as a sulfide by means of ZnS in place of the usual NH_4 sulfocarbonate. No new method is offered for the estn. of the Ni. G. G.

New volumetric method for the estimation of sodium. A. BLENKINSOP. *J. Agr. Sci.* **20**, 511–6(1930). Certain disadvantages of the gravimetric $NaZn(UO_2)_3Ac_9$ method (*C. A.* **22**, 2898; **23**, 462; **24**, 5912), due to manipulative details, are overcome by a proposed method in which the U is detd. by reduction to U^{++++} by means of standard $TiCl_3$ soln. Ppt the Na as $(UO_2)_3ZnNaAc_9\ 6H_2O$, as in the gravimetric method, filter through a Jena glass filtering funnel (porosity G4), remove as much of the reagent as possible by suction and wash 2 or 3 times with 2-cc. portions of a satd. soln. of the ppt. in 95% alc. Dissolve the ppt in dil. HCl, transfer to a 500-cc. conical flask, add about 10 cc of strong HCl and displace the air in the flask by a stream of CO_2. Reduce the U to the uranous state by addn. of an excess of 0.02 *N* $TiCl_3$ soln. Maintaining the CO_2 atm., shake the mixt and allow to stand for 2 or 3 min. or heat to 40–50° to insure complete reduction. Add 20–25 cc. of 2% HF to stabilize, or even ppt., the U. After addn. of about 10 cc. of 10% KSCN, est. the excess of $TiCl_3$ by back titration with 0.02 *N* Fe alum soln. to a permanent red color. P. R. DAWSON

Determination of water in glycerols. L. F. HOYT AND P. C. CLARK. *Soap* **7**, No. 2, 25–27; *Oil & Fat Ind.* **8**, No. 2, 59–61(1931).—Water in concd. glycerols may be detd. directly by the Bidwell-Sterling distn. method using toluene as the boiling liquid. A variable but small amt. of glycerol (never exceeding 0.1 mg.) is carried over with the water, and the correction of the apparent percentage did not exceed 0.15% in any of the glycerols contg. up to 10% of water. The use of xylene b. above 100° is not advisable, as more glycerol is carried over and the time of distn. is not markedly shortened. An analysis of a 25 g. sample of dynamite glycerol to which 2.8 g. of water was added giving 10.37% water, gave a recovery, corrected for 0.036 g. of glycerol carried over, of 10.39% water. E. SCHERUBEL

Determination of phosphoric acid as ammonium phosphomolybdate or as phosphomolybdic anhydride. A. VON ENDRÉDY. *Z. anorg. allgem. Chem.* **194**, 239–57(1930).—For pptg. 0.0003–0.035 P_2O_5, it is recommended to add 8 g. NH_4NO_3, 20 cc. 4 *N* HNO_3 and 20 cc. of reagent (100 g. tartaric acid, 150 g. $(NH_4)_6Mo_7O_{24}\ 4H_2O$, 10–12 drops HNO_3 per l.). Dil. to 100 cc., shake vigorously and filter after the ppt. has settled. Wash the ppt. with 5% NH_4NO_3 which is 0.6 *N* in HNO_3, dry with acetone and weigh

or ignite. The dried ppt. contains 3.55% P_2O_5; after ignition it contains 3.92% P_2O_5. The tartaric acid is added to stabilize the soln. B. A. SOULE

Analysis of gases and vapors which affect oxidation of phosphorus. J. TAUSZ AND H. GÖRLACHER. *Z. anal. Chem.* **83**, 81–92(1931).—A method is given for the analysis of substances like hydrocarbons and $Fe(CO)_5$ which tend to prevent oxidation of P in mixts. with O_2 and air. As indication of the beginning of its oxidation, the luminescence shown by the P can be taken. The pressure of the gas at which this takes place is sharply defined and reproducible so that it can be called the "luminescence pressure." It serves to detect low concns. of impurities which would be difficult to detect in other ways. The literature on this subject of oxidation hindrance from 1797 to the present time is reviewed. The luminescence pressures of mixts. of O_2 and air with the following substances were detd.: benzene, cyclohexane, acetylene, methylcyclohexane, ethylene, propylene, cyclohexene, isoprene and $Fe(CO)_5$. On the basis of these data it is possible to analyze binary gas mixts. of these substances with either O_2 or air. The results quoted were accurate within about 0.05%. W. T. H.

Absorption spectrum of sulfohemoglobin. JEAN PRÉVOT. *J. usines gaz.* 576–80(1930).—H_2S leaves the 2 characteristic bands of hemoglobin unchanged, but adds a new one at 0.610–20μ, the red blood color being changed to olive-green. In analyzing suspected gas mixts. for H_2S the gas was washed with 200 cc. blood soln. in a gas-absorption app. A paraffin oil was used as the replacement fluid, instead of water. A min. of 30 cc. H_2S (room temp. and pressure) produced the characteristic band. CO_2 and O_2 did not interfere. K. H. ENGEL

Notes on the detection of carbon disulfide. F. FEIGL AND K. WEISSELBERG. *Z. anal. Chem.* **83**, 93–104(1931).—The sensitiveness of tests for CS_2 was studied and of 12 methods, the formation of a difficultly sol. Ni salt with "Hector's base," $C_{14}H_{12}N_4S$, proved the most sensitive test. In a small test tube of Jena glass, which is provided with a well-fitting rubber stopper, put a little of the soln. to be tested, a few crystals of $Ni(OAc)_2$ and some of the org. reagent. If the $Ni(OAc)_2$ is insol. in the liquid, add 5–10 drops of water. Stopper the tube, heat a few min. in a water bath, then remove and allow to cool. A pink color will appear if 0.0005 mg. of CS_2 is present in 1 cc. of soln. tested and a red ppt. if much more is present. The ppt. can be weighed and used as the basis of a gravimetric detn. Of the other methods tested, the next-best results were obtained by the reactions with NaN_3 and I_2, in which the CS_2 acts as catalyzer, and with HCHO and Na_2PbO_2; these reactions served to detect 0.002 mg. of CS_2 in 1 cc. of liquid. W. T. H.

A new reaction to differentiate between kaolin and talcum. E. TSCHIRCH. *Seifensieder Ztg.* **57**, 909–10(1930).—Boil about 1 g. of the substance with 10 cc. of 2 *N* HCl, filter, neutralize with AcOH and add 1 cc. of a freshly prepd. 1% alc. soln. of hematoxylin (ext. of "Blue-Wood"); a rose-violet color turning blue-violet (test for Al) indicates kaolin; a yellowish color indicates talcum. P. ESCHER

The chemical analysis of bastnasite. I. P. ALIMARIN. *Trans. Inst. Econ. Mineral.* (Moscow) No **44**, 55–6(1930).—F is sepd. from the decompd. mineral according to Berzelius and detd. by the Merwin colorimetric method. Rare earths and sesquioxides are pptd. with NH_4OH and then sepd. by Peter's oxalate method. Th is sepd. from the Ce and Y groups with H_2O_2 and Ce from the remaining rare earths by Br. Water is detd. by an improved Penfield method. Other common elements are detd. by the usual methods. H. C. PARISH

The determination of sulfate ions in chrome-plating baths. O. MACCHIA. *Industria chimica* **5**, 1346–51(1930).—After a lengthy review of the numerous methods which have been proposed for the detn. of SO_4 ions in chrome-plating solns., including an extensive bibliography, the following method is developed. To 20 cc. of soln. add 20 cc. of glacial AcOH and reduce Cr(6) with NH_2OH or C_6H_5NHOH, adding the reagent until there is no further evolution of gas. Add 150 cc. of water, boil and ppt. with 8 cc. of 10% $BaCl_2$. It is claimed that this method will give results within 5% of the truth. A. W. CONTIERI

Analysis by distillation. HANS WOLFF AND J. RABINOWICZ. *Chem. Fabrik* **1931**, 37–8.—Directions are given for constructing the simple app. and performing distns. by which the characteristics and boiling relations of solvents, single or mixed, may be detd. when only 2–4 cc. of substance is available. Charts show comparative results by this method and the Engler method for benzine, a mixt. of benzine and acetone, and for a mixt. b. 60–200°, but the nature of this mixt. is not stated. J. H. M.

Determination of the constituents of a mixture of volatile liquids. M. LEMARCHANDS. *Bull. soc. chim.* **49**, 80–4(1931).—The method, which can be used for the detn. of alc. and ether in pastes of Poudre B, depends upon the complete vaporiza-

tion of the alc. and ether in a vacuum, the detn. of the quantity of heat absorbed by this vaporization and the wt. of the substances vaporized. The app. consists of a silvered Dewar tube fitted with a stopper carrying a thermometer graduated in tenths of a degree and an Al tube which is provided with an exit tube to be connected with the vacuum pump. The sample is weighed in the Al tube which is placed in the heated Dewar tube which is filled with hot water. The tube is evacuated and the rate of cooling observed. The results obtained were better than those obtained by the usual methods. W. T. H.

Effect of light on the determination of ethylene. J. Louis Oberseider and J. H. Boyd, Jr. *Ind. Eng. Chem., Anal. Ed.* **3**, 123(1931).—By painting the Williams pipet black, except for a narrow vertical strip, the detn. can be made more accurate when made in sunlight, which probably increases the activity of Br upon heavy hydrocarbons so that the C_2H_4 results obtained by absorption in Br aq. are otherwise high when made in sunlight. W. T. H.

Volumetric determination of citric acid in calcium citrate. G. Romeo. *Rivista ital. essenze profumi* **11**, xxiii-xxvi(1929); cf. *C. A* **24**, 2963.—The Ca citrate is converted into the K salt and treated with an excess of standard $AgNO_3$ soln., the excess being titrated with thiocyanate. Oxalic acid, tartaric acid, HCl and H_3PO_4, but not $CaSO_4$ nor pectic substances, interfere. B. C. A.

Color reaction of glycerol with alkali thiosulfates. D. Ganassini. *Arch. ist. biochim. ital.* **2**, 239–42(1930).—Most of the color reactions of glycerol are due to its products of oxidation or dehydration. Of these, acraldehyde, which is formed by heating with $KHSO_4$ (or B_2O_3 or P_2O_5) either glycerol or its derivs., may be identified by spontaneous conversion of its phenylhydrazone into phenylpyrazoline, this giving an intense violet coloration in the presence of oxidizing agents in acid soln. Powd. $Na_2S_2O_8$ dissolves in very concd. glycerol soln., with slight heating, to a colorless soln., which becomes sky-blue and then deep indigo when heated to boiling. This reaction is not given by carbohydrates in general, but a much less intense coloration is obtained with the polyhydric alcs. To sep. glycerol from org. liquids and tissues, the material is mixed with water and filtered, the filtrate being treated with a slight excess of basic Pb acetate and filtered. After removal of the Pb as sulfide, the liquid is evapd. to dryness with milk of lime, the residue being extd. with a mixt. of 95% alc. (2 parts) and Et_2O (1 part) and the soln. evapd. to a sirup, to which the above test is applied. To ext. glycerol present as glycerides, glycerophosphate or lecithin, the material must first be hydrolyzed with NaOH. The coloration given with thiosulfate appears to be due to the transitory formation of the unstable blue modification of S. The test may be used also for the detection of thiosulfate. B. C. A.

New analytical applications of the reaction of ammonia on resorcinol in the presence of cations. Ligor Bey. *Bull. soc. chim.* [4], **47**, 1192–3(1930); cf. *C. A.* **23**, 4909, **24**, 2397.—NH_3 was added to a 5% soln. of resorcinol in ether, just to the point of re-solution. A soln. contg. 0.0011% $CdCl_2$ $2H_2O$, added carefully, gave a blue ring at the junction of the 2 layers in 26 min. It persisted 5–10 min. Lower concns. gave a noncharacteristic violet. In the analysis for Sn, stannic Sn gave the best results. The Sn was oxidized with Br until the soln. was a light yellow. Two or 3 cc. was shaken with 5 cc. NH_3 (d. = 0.925) for several min.; 2 or 3 cc. of 5% aq. resorcinol was added, giving a white ppt. of $Sn(OH)_4$, which turns blue in 2–20 min. This test is sensitive to 0.0015% $SnCl_2$ $2H_2O$. Lower concns. gave a noncharacteristic gray. The result is not affected by less than 400 times as much Sb as Sn. G. M. P.

Detection and estimation of hydroxyl groups in organic compounds. Huppmann. *Pharm. Ztg.* **76**, 113–4(1931).—This is a commentary on the usual methods (by the aid of AcCl, Ac_2O and BzCl) in connection with expts. on resorcinol, orcinol, Me salicylate and 2,7-hydroxytetralol, in which the procedure of Verley and Bölsing was used. W. O. E.

Iodoxybenzoate as a test reagent for free phenolic hydroxyl groups in organic compounds. Chauncey D. Leake. *Proc. Soc. Exptl. Biol. Med.* **28**, 148–50(1930).—Morphine salts treated with an aq. soln. of NH_4 iodoxybenzoate give a straw to garnet color reaction. No other opium alkaloid, except apomorphine, gives a color with this reagent. The reagent does not decompose the compds. with which it comes in contact; it reveals by an oxidizing color reaction the presence of a "free" phenolic hydroxyl group. The test should be useful in detecting and differentiating morphine and apomorphine from other opium alkaloids, adrenaline from ephedrine, acetarsone from other quinquevalent arsenicals. It detects phenol and cresol as preservatives in org. fluids. The test substance need not be miscible with the reagent; thorough shaking is sufficient. The pharmacol. effect of substances treated with this reagent does not

seem to be altered. Substances such as codeine, in which the H of the phenolic hydroxyl group is replaced, have much less toxicity and general pharmacol. action than the parent substances. C. B. BAILEY

Detection of hydrogen in volatile organic compounds. IRWIN STONE. *Chemist Analyst* **20**, No. 2, 7(1931).—By passing the vapors through a small opening so that they strike against hot CuO in a test tube, water is formed and condenses on the upper walls of the tube. W. T. H.

Note on the Ter Meulen-Heslinga methods for the estimation of nitrogen, carbon and hydrogen in organic material. E. P. GRIFFING AND C. L. ALSBERG. *J. Am. Chem. Soc.* **53**, 1037–9(1931).—This is a discussion and suggestion of modifications of the methods for N, C and H developed by Meulen and Heslinga (cf. *C. A.* **19**, 226, 2465). C. J. WEST

A method for the (mercurometric) determination of formaldehyde and hexamethylenetetramine. ENRIQUE E. REBAGLIATI. *Ann. Farm. Bioquim.* **1**, 150–8(1930).—The substances are reduced with the aid of Knapp's reagent, modified, and the final detn is accomplished by titration with 0.1 *N* $AgNO_3$ according to the method of Denigès. R. claims that the method is rapid and exact. B. S. LEVINE

New method for the estimation of halogens in organic substances. JUAN A. SANCHEZ. *Ann. farm. bioquim.* **1**, 121–34(1930).—Heat the org. substance in a closed tube together with solid K_2MnO_4, ext with water and destroy the excess of the reagent with H_2O_2. Det. the halogen titrimetrically. The method can be applied to quantities of org. matter as low as 0.02 g. It is applicable with a high degree of precision to aliphatic and cyclic derivs. and to substances rich in C and poor in halogen, and *vice versa* The detn. of halogens in substances such as C_6Cl_6 and the halogen derivs. of phenyl is accomplished with greater ease than by the method of Carius. B. S. LEVINE

The activity of Professor F. Wald in analytical chemistry (QUADRÁT) **2.** Conductivity measurements and titrations (HAHN) **2.** Oxidation of heterocyclic As compounds by I (RAZUVAEV, MALINOVSKII) **10.**

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Gallium. IV. Occurrences of gallium in zinc minerals. JACOB PAPISH AND CHESTER B. STILSON. *Am. Mineral.* **15**, 521–7(1930).—The arc spectrographic method, with graphite and also Ag electrodes, was used in a study of a no. of Zn minerals for the detection of Ga. The relative intensity of the Ga lines is listed. Sphalerite, gahnite, hopeite, parahopeite and adamite were found to be galliferous. Ga was not detected in calamine, smithsonite, zincite, hydrozincite, goslarite, hodgkinsonite, hardystonite and clinohedrite. A. M. BRANT

Tellurium and tellurium minerals of Hungary. S. KOCH. *Bányás. Kohás Lapok* **62**, 425–9, 449–52(1929).—Te is the one element discovered by a Hungarian scientist, Pál Kitaibel. Eleven Te minerals are found in Hungary, ten of which were first described there. The genetic relations of these are summarized. Native Te of Facebánya contained 0.15–2.78% Au. Tetradymite, hessite, wehrlite, petzite, muthmannite, krennerite, sylvanite, nagyágite, tellurite and stützite are described. The mines which once yielded such Au-contg. tellurides belong now to Roumania, and most of them are not being worked. S. S. DE FINÁLY

Notes on rickardite, a new occurrence. WM. P. CRAWFORD. *Am. Mineral.* **15**, 272–3(1930).—Rickardite, Cu_4Te_3, has been found in the sulfide ores of the Brigg's mine, Warren, Ariz. A. M. BRANT

Crystallography of stibnite and orpiment from Manhattan, Nevada. CHARLES PALACHE AND DAVID MODELL. *Am. Mineral.* **15**, 365–74(1930).—The crystallographic features are given in detail. The data on orpiment give addnl. proof that the mineral is monoclinic. A. M. BRANT

Crystal habit of zinc blende. G. KALB AND L. KOCH. *Centr. Mineral. Geol* **1929A**, 353–7.—Zn blende is referred to the octahedral isoharmonic crystal type; 2 forms, resp., black and reddish brown to reddish yellow, are distinguished. B. C. A.

Arsenoferrite from Jachymov, Czechoslovakia. Wm. F. Foshag and M. N. Short. *Am. Mineral.* 15, 428–9(1930).—This mineral, $FeAs_2$, is the arsenide member of the pyrite group. It is isotropic in character, differing from löllingite which is anisotropic. It can be distinguished from smaltite only by chem. tests. The color is dull medium gray. The phys. properties are: metallic luster, no cleavage, hardness 5.5, sp. gr. 6.42. Jachymov arsenoferrite occurs as fine-grained irregular masses in a carbonate gang. Chem. analysis of material contg. some gang gave: Fe 24.88, Cu 1.34, Pb 0.05, $CaCO_3$ 34.00, $MgCO_3$ 1.57, As 66.84, S 1.08, sum 99.76%; Co and Ni were not detected. The blowpipe characteristics are the same as those for löllingite. A. M. Brant

The crystal structure of cryolithionite. G. Menzer. *Z. Krist.* 75, 265–87(1930).—A detailed report of the structure of $Li_3Na_2Al_2F_{12}$ (cf. *C. A.* 22, 2340). The side of the unit cube is 12.097 ± 0.004 A. U. and the calcd. d. is 2.791. Coördinates for the F atoms are 0.035, 0.04 and 0.64 (all ±0.01). Although the structure is analogous to that of garnet, the diffraction effects are quite different, for in garnet the O atoms are almost negligible, while in cryolithionite the corresponding F atoms are the most important. L. S. Ramsdell

Boleite, pseudoboleite and cumengeite. B. Gossner. *Z. Krist.* 75, 365–7 (1930).—A criticism of the structure detn. of Friedel and Hocart (*C. A.* 24, 4734). G. maintains that the x-ray data show boleite to be cubic and not tetragonal. L. S. Ramsdell

Origin, weathering and artificial coloring of agate. H. Heinz. *Chem. Erde* 4, 501–25(1930).—The different layers in agates were examd. chemically, optically and by x-rays. Analyses are given of the white weathered crust and of the fresh agates; *e. g.*, flint from the English chalk gave I for the inner black portion and II for the white chalk-like crust.

	SiO_2	$(Fe,Al)_2O_3$	(Mg,Mn)O	CaO	Ign.	D.
I	97.93	0.27	0.20	0.59	1.25	2.596
II	96.72	0.28	0.09	1.71	1.68	2.501

The portion sol. in 10% KOH soln., taken to represent admixed opal, varies in different bands from 5.02 to 30.69%, with a corresponding range in d. from 2.620 to 2.601. Artificial coloring, by soaking in sugar soln. for 14 days and then in concd. H_2SO_4, was effected in the finer-grained layers contg. more opal, rather than in porous weathered layers. Banded and tubular structures, similar to those seen in agates, were obtained experimentally by the interaction of silicic acid sols and salt solns. B. C. A.

Agate. G. Linck and H. Heinz. *Chem. Erde* 4, 526–8(1930).—A discussion of the preceding abstr. The banding of agate is attributed to the alternating action of solns. of silicic acid and of salts, the former during the dry season and the latter during the wet season of the year. B. C. A.

The relations of magnetite and ilmenite in the magnetite deposits of the Duluth gabbro. G. M. Schwartz. *Am. Mineral.* 15, 243–52(1930).—Polished surfaces of the titaniferous magnetite ores and gabbro were examd. in reflected light. The Ti was found to occur only in the form of ilmenite, as grains and as intergrowths along the parting planes of magnetite. The intergrowths are estd. to amount to 15% of the ore. Their texture is attributed to the breaking down of a solid soln. A. M. Brant

Four stages in the alteration of the Villeneuve uraninite. H. V. Ellsworth. *Am. Mineral.* 15, 455–60(1930).—The specimen, found in 1886, shows well-marked zones of material due to progressive alteration. The central zone A has a steely blue-black color, hardness 6, sp. gr. 9.144; zone B has a pitch-black color, hardness 4.5, sp gr. 7.779; zone C has a bright "flame-scarlet" color, hardness 3.5, sp. gr. 5.273, waxy luster; zone D is a very thin irregular layer with hardness 3 and has a buff to apricot-yellow color and waxy luster. The chem. analysis of the first 3 are tabulated. The results indicate that when analyzing altered uraninites for age detns., all red and yellow alteration products should be excluded. This is due to the abnormal increase in the Pb-Ur ratio in these products. A. M. Brant

Uraninite from Placer de Guadalupe, Chihuahua. Roger C. Wells. *Am. Mineral.* 15, 470–3(1930).—The mineral occurs in a calcite vein about 2 ft. thick between porphyry and shale. It is intimately assocd. with Au. The nodules range from small specks to the size of a walnut. Above the water level the pitchblende is leached out leaving wires of Au and small quantities of uranophane and a dark green U mineral. The mean of 2 analyses is: UO_3 70.09, UO_2 22.69, ThO_2 0.20, CeO_2 0.71, La_2O_3 etc., 1.02, Y_2O_3 etc., 3.41, Fe_2O_3 0.10, As_2O_3 0.06, PbO 0.40, CaO 0.30, TiO_2 0.06, Al_2O_3 0.25, H_2O (0.41), sum 99.70%. The age of the veins calcd. from the Pb-Ur ratio

is 36 million years. The sp. gr., 10.63, detd. by pycnometer, is the highest so far reported for uraninite. A. M. BRANT

Euhedral magnesite crystals from Winkler County, Texas. JOHN T. LONSDALE. *Am. Mineral.* 15, 238–9(1930).—Magnesite crystals 1–5 mm. long were obtained from drill cores at 2690 feet. The matrix is dolomite limestone contg. flint nodules. Many of the crystals are stained with petroleum or asphalt. A. M. BRANT

The occurrence of magnesite and of iron ores at Tarrekaisse, Sweden. ALVAR HÖGBOM. *Geol. Fören. Förh.* 52, 417–30(1930).—The magnesite is usually accompanied by chlorite, asbestos and magnetite. The probable formation of the ores is discussed. WILHELM SEGERBLOM

Feldspars in the Adirondack anorthosite. HAROLD L. ALLING. *Am. Mineral.* 15, 267–71(1930).—A discussion of an article by Barth (*C. A.* 24, 5258). A. concludes that (1) the plagioclase of the Adirondack anorthosites consists of labradorite grading into andesine with an appreciable though small percentage of K-feldspar in solid soln., and (2) late-stage interstitial feldspars are Na-rich anorthoclases and K-bearing oligoclases. The latter may be untwinned. A. M. BRANT

A chromium-bearing pyroxene from Jagersfontein, S. Africa. H. O'DANIEL. *Z. Krist.* 75, 575(1930).— This dark-green mineral occurred as a nodule in the blue-ground. The angle between the 110 and $1\bar{1}0$ cleavages was 92°49′; between 110 and 001, 79°7′. Analysis gave: SiO_2 53.53, Al_2O_3 1.30, Cr_2O_3 1.96, FeO 2.10, CaO 22.96 and MgO 17.88, sum 99.73%; n_D: α 1.6722, β 1.6847, γ 1.7015. L. S. RAMSDELL

A titaniferous augite from Chaudrawati, Sirohi State, Rajputana. A. L. COULSON. *Records Geol. Survey India* 63, 448–50(1930).—The mineral occurs in a contact metamorphic product at the junction of olivine gabbro with calcic rock. Its assocd. minerals are calcite, wollastonite, pectolite, quartz, microcline, orthoclase, plagioclase and magnetite. Optical data are given. ALDEN H. EMERY

Iron-rhodonite from Tuna Hästberg. N. SUNDIUS. *Geol. Foren. Forh.* 52, 401–6 (1930).—An ore found at Tuna Hastberg was a very Mg-poor olivine holding 27.9% MnO and 40% FeO, small grains of garnet and a pyroxene-like mineral which made up 4 to 5% by vol. of the ore. The last-named mineral was found to be an Fe-rich rhodonite with the compn.: SiO_2 47.78, Al_2O_3 0.08, Fe_2O_3 0.11, FeO 14.51, MnO 29.20, MgO 1.93, CaO 6.55, H_2O 0.09, sum 100.25%. The mineral is colorless or slightly pink and has 2 excellent cleavages nearly at right angles to each other. Discussion of the work of Weibull and of Palmgren and Sobral on similar minerals leads S. to conclude that the name iron-rhodonite should be reserved for members of the series which contain considerable amts. of FeO. WILHELM SEGERBLOM

The structure of anthophyllite, $H_2Mg_7(SiO_3)_8$. B. E. WARREN AND D. I. MODELL. *Z. Krist.* 75, 161–78(1930)(in English).—Anthophyllite is the simplest orthorhombic amphibole. X-ray data lead to the formula $H_2Mg_7(SiO_3)_8$ rather than $MgSiO_3$. Rotation photographs give a = 18.5, b = 17.9 and c = 5.27 A. U. The unit contains 4 mols. and the space group is V_h^{61}. Compared with enstatite (*C. A.* 25, 1420) the values for a and c are identical, but b for anthophyllite is twice that for enstatite. A block of enstatite is multiplied by the action of symmetry planes to form the anthophyllite cell, except for $^1/_8$ of the Mg atoms, which fall in unlikely positions and drop out. Each Si is surrounded by 4O atoms tetrahedrally arranged. Sharing of tetrahedra corners gives rise to the characteristic amphibole double Si-O chains. One-twelfth of the (O, OH) positions are not bound to Si, but to only 3Mg. These are only singly charged and must be OH. The general relations between amphiboles and pyroxenes are discussed. L. S. RAMSDELL

Soda-rich anthophyllite asbestos from Trinity County, California. J. D. LAUDERMILK AND A. O. WOODFORD. *Am. Mineral.* 15, 259–62(1930).—The country rock is serpentine contg. minute branching veins of chrysotile and much thicker veins (up to 5 cm.) of amphibole asbestos. They are short branching and lie in the crushed slickensided rock in roughly parallel positions. The fibers are usually perpendicular to the walls. The material was found to be anthophyllite with α = 1.606, β = 1.613, γ = 1.623. Z, parallel to elongation, was pale yellow green, in the other directions colorless. Analysis gave: SiO_2 57.70, Al_2O_3 2.00, Fe_2O_3 trace, FeO 5.32, MgO 21.12, CaO 5.10, Na_2O 7.40, K_2O absent, MnO trace, H_2O^+ 1.80, H_2O^- 0.30, sum 100.74%. A. M. B.

An association of anthophyllite and enstatite. F. COLES PHILLIPS. *Geol. Mag.* 67, 513–6(1930).—These minerals were observed in thin-sections of rocks from the Shetland Islands. The anthophyllite shows a variable degree of alteration to talc. The enstatite is of later formation than the anthophyllite, but there is little evidence that the pyroxene formed at the expense of the amphibole. A. M. BRANT

Hypersthenization and its explanation. D. GUIMARAES. *Ann. acad. brasil. sci.* **2**, 1–11(1930).—The formation of hypersthene from diopside by way of clinoenstatite is discussed from the crystallographic point of view, and a general theory is put forward to account for the chem. transformations which have occurred for silicate minerals. It is supposed that at high temps. and pressures the small quantity of water present acts as an electrolyte, and interaction of silicates, or of silicates and SiO_2, and the transformation of one mineral into another is possible in directions controlled by the H-ion concn. B. C. A.

Tremolite from near Jasidih, Bihar. A. L. COULSON. *Records Geol. Survey India* **63**, 444–6(1930). ALDEN H. EMERY

Changes in hornblende at about 800°. VIRGIL E. BARNES. *Am. Mineral.* **15**, 393–417(1930).—A set of 14 samples of hornblende including edenite and pargasite and 6 of the tremolite-actinolite series were studied optically before and after heating in air. The samples were later heated to 850° in a stream of H and the optical properties again studied The results are given in tabular and graph form. It was found that green hornblende when heated in air changes to brown hornblende, with the optical properties of basaltic hornblende. The Fe-poor hornblendes do not change on heating. Tremolite behaves like the Fe-poor hornblendes and actinolite like the iron-rich ones. The changes observed in heating the latter are: an increase in d., *ns*, birefringence and dispersion; a decrease in extinction angle; a change in optic angle to about 65°; a change in pleochroism from greens to browns. The birefringence of brown hornblende in violet is greater than that for red, and the opposite is in general true for common hornblende. The wt.-% loss on heating is only a fraction of the H_2O obtained by analysis; there is marked conversion of Fe^{++} to Fe^{+++}. Heated hornblendes in general show a more complete change in Fe^{++} than basaltic hornblendes. Dehydration has little effect on the optical properties, but they change almost in proportion to the change in the total Fe oxides, with Fe^{+++} being especially influential. Brown hornblende when heated in H changes back to green hornblende. Inversion does not take place. In dehydration, H and not H_2O (except that which is not a constituent part of the space lattice) is given off. The O remains in the mineral, either oxidizing Fe^{++} to Fe^{+++}, or in the absence of Fe^{++} remaining free because of its size. A. M. BRANT

Notes on some Franklin minerals. L. H. BAUER AND HARRY BERMAN. *Am. Mineral.* **15**, 340–8(1930).—*Cummingtonite* (Zn, Mn-bearing) was found embedded in rhodonite or garnet. The green prismatic crystals have a cleavage angle of 54°28′. The chem. compn. is: SiO_2 49.74, Al_2O_3 1.72, FeO 12.80, MgO 8.31, ZnO 10.46, MnO 13.79, CaO 0.49, Na_2O 0.22, H_2O^+ 2.16; sum 99.69%. The optical properties are: biaxial −, 2V = 75°, ZAc = 15°, Y = b, α = 1.657, β = 1.674, γ = 1.685. *Apophyllite* found as pale-pink radiating crystals in limestone has the compn. SiO_2 50.90, CaO 24.74, K_2O 3.70, Na_2O 0.42, MnO 0.47, ZnO 1.79, H_2O 17.71%. The derived formula is (Ca, K, Na, Mn, Zn)$_2$ $Si_8O_8.3^1/_2H_2O$. *Barysilite* occurs as thin films and veinlets assocd. with garnet, axinite, hardystonite. The chem. compn. is: SiO_2 16.84, PbO 77.35, MnO 3.33, FeO 0.23, Al_2O_3 0.59, CaO 0.21, MgO 0.78, ZnO 0.30, H_2O 0.07, sum 99.70%; the formula is $3PbO.2SiO_2$. The optical properties are: uniaxial−; ω = 2.033, ϵ = 2.015. *Celestite* is reported from Sterling Hill. It occurs in cavities in franklinite ore as good crystals tabular parallel to *a*(100). *Chlorophoenicite* (previously described as clinozoisite) is compared with that mineral. *Datolite* has been found in crystals tabular to *b*(010). *Ferroschallerite*, in which the Mn of schallerite is partially replaced by Fe, has the compn.: SiO_2 31.12, MnO 29.22, FeO 17.12, MgO 0.12, ZnO 3.63, As_2O_3 12.46, H_2O 6.42, sum 100.09%. A single specimen of *manganbrucite* was found. This had a Mg to Mn ratio of 5:1. The chem. analysis of *svabite* is: insol. 0.29, H_2O 1.32, F 1.41, CO_2 trace, CaO 45.89, ZnO 1.54, MnO 1.23, MgO 0.84, PbO 0.51, As_2O_5 35.24, P_2O_5 12.54, sum, corrected for O = F_2, 100.22%; sp. gr. is 3.542 and ω = 1.684. The relations of the members of the apatite-svabite series are discussed. A. M. BRANT

The structure of hardystonite, $Ca_2ZnSi_2O_7$. B. E. WARREN AND O. R. TRAUTZ. *Z. Krist.* **75**, 525–8(1930)(in English).—From rotation and oscillation photographs it is shown that the unit cell and space group of hardystonite are the same as those found for melilite (*C. A.* **24**, 4736). The dimensions are a = 7.83, c = 4.99 A. U., c/a = 0.637. The at. arrangement is the same as in melilite, except that the (Mg, Al) is replaced by Zn. L. S. RAMSDELL

Crystal lattice of eulytite, $Bi_4Si_3O_{12}$. G. MENZER. *Centr. Mineral. Geol.* **1928A**, 420–1.—Powder photographs show a cubic, space-centered lattice, a_0 10.25 ± 0.02 A. U.; d. 6.32 ± 0.21. If a mol. wt. of 1109 is assumed, there are 3.7 mols. in the unit cell. B. C. A.

The structure of danburite, $CaB_2Si_2O_8$. C. DUNBAR AND F. MACHATSCHKI. *Z. Krist.* **76**, 133–46(1930)(in English).—The orthorhombic unit cell has the dimensions $a = 8.75$, $b = 8.01$ and $c = 7.72$ A. U. If the symmetry is holohedral, the space group is V_h^{16}. There are 4 mols. in the cell. The unit of structure is not an SiO_4 group, but rather Si_2O_7, 2 tetrahedral groups being linked by a common O atom. The eighth O atom forms a tetrahedron with O atoms from $3Si_2O_7$ groups. The B atoms are at the centers of these tetrahedra. Although the presence of B makes the detn. of structure difficult, parameters are derived for all positions. L. S. RAMSDELL

Zoisite and its native rock from the high mountains of Västerbotten. ERLAND GRIP. *Bull. Geol. Inst. Univ. Upsala* **22**, 289–98(1930).—Three samples of amphibolite from different localities were examd. The rock is dark grayish green, somewhat slate-like, with porphyritic injections of zoisite in a granular base of hornblende, plagioclase and quartz. The long, flat, striated zoisite needles are white with a tinge of green, and are, in general, oriented with respect to the cleavage plane (100). The optical orientation is $\alpha = c$, $\beta = b$, $\gamma = a$. The sp. gr. is 3.368, it is optically + and $2V = 30–56°$; $\alpha = 1.7011$, $\beta = 1.7020$, $\gamma = 1.7073$. Analysis gave: SiO_2 39.37, Al_2O_3 32.06, Fe_2O_3 1.47, FeO 0.15, MnO 0.02, CaO 24.32, MgO none, TiO_2 0.36 and H_2O 1.89%. Descriptions and analyses of the other mineral constituents are included. The composite material from Spängfjället, sp. gr. 3.090, contained hornblende 70.7, zoisite 10.3, quartz 7.7, plagioclase 3.5, garnet 5.7 and titanite 2.1% by wt. W. L. HILL

Sapphirine in the Vizagapatam district. H. CROOKSHANK. *Records Geol. Survey India* **63**, 446–8(1930)—The material occurs as a thin rim around grains of hercynite Optical data are given. ALDEN H. EMERY

Formulization of silicates. W. KUNITZ. *Chem. Erde* **4**, 549–50(1930).—A further discussion of the chem. formula of tourmaline, with comparison of the views of K. (*C. A.* **25**, 1461) and of Machatschki (*C. A.* **23**, 5132 and *C. A.* **25**, 1461). To conform with the detn. that the unit cell contains 3 mols., the empirical formula may be multiplied by 3/2 or 9/4. B. C. A.

The space lattice of natrolite. FRANZ HALLA AND ERNST MEHL. *Z. Krist.* **75**, 421–9(1930).—The orthorhombic unit cell of natrolite has the dimensions $a = 18.384 \pm 0.004$, $b = 18.715 \pm 0.027$ and $c = 6.632 \pm 0.008$ A. U. It contains 8 mols. of $Na_2Al_2Si_3O_{10}.2H_2O$. If holohedral symmetry is assumed, the space group is V_h^{23}; otherwise it is C_{2v}^{18} or V^7. L. S. RAMSDELL

The crystal structure of muscovite. W. W. JACKSON AND J. WEST. *Z. Krist.* **76**, 211–27(1930)(in English).—The structure for muscovite proposed by Pauling (*C. A.* **24**, 2694) has been confirmed, and the details of the structure are discussed. Four mols. of $KAl_2(AlSi_3)O_{10}(OH)_2$ are in the monoclinic unit, with $a = 19.96$, $b = 9.02$, $c = 5.18$ A. U. and $\beta = 95°30'$. The close relations between diopside, tremolite and muscovite are discussed. L. S. RAMSDELL

The structure of chrysotile, $H_4Mg_3Si_2O_9$. B. E. WARREN AND W. L. BRAGG. *Z. Krist.* **76**, 201–10(1930)(in English).—Chrysotile (variety of serpentine) occurs only in bundles of parallel fibers, with random orientation about the fiber axis (= c axis) It is not possible to obtain rotation photographs about any other axes, and exptl. data are consequently meager. This proposed structure is believed, however, to be correct in its main features. The unit cell is monoclinic, with $a = 14.66$, $b = 18.5$, $c = 5.33$ A. U. and $\beta = 93°16'$. The space group is probably C_{2h}^3. The unit contains 4 mols. of $(OH)_6Mg_6Si_4O_{11}.H_2O$. Each Si atom is surrounded by a tetrahedron of O atoms. Sharing of O atoms by adjacent tetrahedra gives rise to double Si-O chains, just as in the amphiboles. These have the compn. Si_4O_{11}, and between them lie sections of Mg and OH arranged as in brucite ($Mg(OH)_2$). Although the formula calls for $4H_2O$, these are not H_2O mols, as each H is shared by 2O atoms. The lateral binding between the chains is very weak, the perfect fibrous character of chrysotile being thus accounted for. L. S. RAMSDELL

Aluminum silicate from Allchar, S. Serbia. F. TUCAN. *Bull. soc. franç. minéral.* **52**, 42–7(1929).—The product, having a compn. corresponding with the formula $Al_2O_3.3SiO_2.7H_2O$, has d_{22} 1.9818; when heated it evolves water (completely at 650°) having an acid reaction. The dehydration curve ($CaCl_2$, H_2SO_4 or P_2O_5 being used) is continuous. B. C. A.

The chemical composition of lessingite and cerite from the Kyshtym district. YU. N. KNIPOVICH. *Trans. Inst. Econ. Mineral. and Met.* (Moscow) No. **44**, 46(1930).—The formula for the new mineral lessingite may closely approach $H_3Ca_2Ce_4Si_3O_{16}$. On the assumption of the presence of an admixt. of bastnäsite, the compn. of the cerite is

$4Ce_2O_3.6SiO_2.H_2O$ which closely approaches Swedish cerite but contains less H_2O.
H. C. PARISH

Cenosite from North Burgess Township, Lanark County, Ontario. R. P. D. GRAHAM AND H. V. ELLSWORTH. *Am. Mineral.* **15**, 205–19(1930).—The mineral occurs as minute pink or pale rose colored crystals on calcite and quartz in soln. cavities in a coarse granular limestone. Chalcopyrite and celestite are also present. It is orthorhombic in crystn., prismatic in habit. The mineral is optically −, with 2 V about 39°45′, $\alpha = 1.644$, $\beta = 1.689$, $\gamma = 1.691$. Orientation $a = \alpha$, $b = \beta$, $c = \gamma$. Other phys. properties are: hardness 5–6, sp. gr. 3.612, vitreous to pearly luster, no cleavage. Chem. analysis gave: SiO_2 34.66, $(Ce, La, Di)_2O_3$ 3.22, $(Yt, Er)_2O_3$ 35.46, CaO 16.72, SrO 0.31, Al_2O_3, Fe_2O_3, BeO 0.22, MnO 0.02, Na_2O 0.27, K_2O trace, MgO 0.19, CO_2 6.58, SO_3 0.04, H_2O 2.54, H_2O (110–130°) 0.04, sum 100.23%; formula deduced, $2CaO.(Ce, Yt)_2O_3.CO_2.4SiO_2.H_2O$.
A. M. BRANT

Allodelphite, a new silicoarsenite from Långban. P. QUENSEL AND H. VON ECKERMANN. *Geol. Fören. Förh.* **52**, 639–46(1930).—The mineral which Flink labelled "undescribed mineral no. 325" in his catalog of new minerals from Långban (cf. *C. A.* **19**, 2623; **20**, 1778) is now named *allodelphite* to show its relation to synadelphite. Allodelphite occurs as thin crusts of small well-defined elongated tabular crystals of a dark red-brown color, but deep wine red in transmitted light. The luster is submetallic, fracture conchoidal and streak chocolate brown. It is optically −; sp. gr. = 3.573. The compn. is: SiO_2 6.23, As_2O_5 21.91, As_2O_3 0.62, Sb_2O_5 0.15, Al_2O_3 1.50, Fe_2O_3 0.98, PbO 0.39, MnO 50.30, CaO 1.10, MgO 6.22, K_2O 0.74, Na_2O 0.53, H_2O 8.82, sum 99.49%. Allodelphite is evidently a new representative of the small group of silicoarsenates or silicoarsenites. Two general formulas are suggested: $9RO.As_2O_5.SiO_2.5H_2O$ and $5RO.2R_2O_3.As_2O_5.SiO_2.5H_2O$. Q. and E. discuss these in the light of a new analysis of the related mineral synadelphite and conclude that, pending further investigation, the formula of allodelphite may be assumed to be $MnO.(Mn_2, As_2, MnSi)O_3.H_2O$. W. S.

The hiddenite deposit in Alexander County, North Carolina. CHARLES PALACHE, S. C. DAVIDSON AND E. A. GORANSON. *Am. Mineral.* **15**, 280–302(1930).—The genetic history of this deposit was traced, 3 stages of mineralization being distinguished, as follows: (1) the *lit-par-lit* pegmatite stage, (2) the hiddenite pegmatite stage, (3) the hiddenite cavity stage. The minerals of the latter stage are described in some detail. The optical properties of *hotmquisitite* are $\alpha = 1.625$, $\beta = 1.645$, $\gamma = 1.654$; pleochroism X = light yellow, Y = violet, Z = purplish violet; Z nearly parallel to *c*; dispersion weak $\rho > v$; 2V = 51°. The mineral is compared as to chem. compn. with the find at Utö, Sweden.
A. M. BRANT

Paragenesis of the Newry pegmatite, Maine. H. J. FRASER. *Am. Mineral.* **15**, 349–64(1930). Structural and textural data indicate 3 periods during the formation of the pegmatite, and that the process was essentially continuous. In the first period mainly silicates were deposited. During the second period these changed to Li silicates and phosphates. The third period was one of deposition of Mn, Fe, Al and Be phosphates.
A. M. BRANT

Pegmatite minerals of Poland, Maine. HARRY BERMAN AND F. A. GONYER. *Am. Mineral.* **15**, 375–87(1930). The minerals found in pockets in microcline comprised: *amblygonite*, as a compact rim around the pockets; *lithiophilite*, partially replaced by reddingite. The chem. compn. is: FeO 10.96, MnO 31.90, Na_2O 0.30, Li_2O 9.55, H_2O + 0.40, P_2O_5 46.35, insol. 0.16, sum 99.62%. The optical properties of the analyzed material were: biaxial +, 2V = 60°; α and γ parallel to cleavages. $\alpha = 1.675$, β 1.679, γ 1.688. *Rhodochrosite* occurs as an irregular layer over the amblygonite contg. cavities with small protruding crystals of the mineral, strongly etched. *Quartz* occurs as min. doubly terminated crystals in veinlets in the rhodochrosite. *Eosphorite* (cf. Drugman *C. A.* **10**, 31) occurs as well-formed crystals embedded in rhodochrosite. *Reddingite* replaces rhodochrosite as granular masses and as veinlets in lithiophilite. The color varies from colorless to deep brownish red, depending on the degree of alteration to landesite. The chem. compn. is: Fe_2O_3 0.95, FeO 12.68, MnO 38.36, CaO 0.15, $Na_2O.K_2O$ trace, H_2O + 13.16, P_2O_5 34.52, insol. 0.45, sum 100.27%; formula $3(MnFe)O.P_2O_5.3H_2O$, with Mn:Fe = 3:1; optically biaxial + with 2V = 65°; $\alpha = 1.655$, β 1.662, γ 1.683. *Dickinsonite* occurs as small, tabular, highly etched crystals assocd. with fairfieldite. The color is brownish to yellowish green. The chem. compn. is: FeO 12.33, MnO 31.83, MgO 1.67, CuO 2.01, Na_2O 7.41, K_2O 1.73, Li_2O 0.20, H_2O 1.82, P_2O_5 40.78, insol. 1.00, sum 100.78%; formula $7(MnFe)O.2(Na_2K_2Ca)O.3P_2O_5.H_2O$; optically biaxial + with 2V near 90°; $n\alpha = 1.648$, $\beta = 1.655$, $\gamma = 1.662$. *Fairfieldite* occurs as white foliated plates in rhodochrosite and on dickinsonite. Its compn. is: FeO 4.74, MnO 14.82, CaO 30.85, Na_2O 0.41, K_2O none, H_2O 9.70, P_2O_5 39.55, insol.

0.50, sum 100.58%; formula $(MnFe)O.2CaO.P_2O_5.2H_2O$, with Mn:Fe::3:1; optically biaxial + with 2V = 86°; α = 1.640, β = 1.650, γ = 1.660. *Apatite* occurs as small "nailhead" crystals resting on the other crystals. *Landesite*, a new mineral, is a brown alteration product of reddingite. The crystals are rough and of a form suggesting the unit pyramid of the latter. Two cleavages are shown. The chem. compn. is: Fe_2O_3 + FeO 13.91, Mn_2O_3 2.69, MnO 33.65, MgO 3.07, CaO 1.39, H_2O 13.60, P_2O_5 31.94, insol. 0.13, sum 100.38%. This analysis yields the formula $3Fe_2O_3$.-$20MnO.8P_2O_5.27H_2O$. The mineral is related to salmonsite in compn. and to sicklerite in optical properties. These are: biaxial −, 2V large; Z perpendicular to best, and X to an inferior cleavage; pleochroism X = dark brown, Y = light brown, Z = yellow; α 1.720, β 1.728, γ 1.735. *Cassiterite* is contemporaneous with rhodochrosite. It is identified optically by the following: uniaxial+; ω = 2.01 = light green, ϵ = brown. The pleochroism is worthy of note. A *beryl* crystal from this locality has on the base an excellent etch figure of the forms $(10\bar{1}1)$ and $(11\bar{2}1)$. Its ω = 1.585, indicating high alkali content and probably Cs. This crystal was not a part of the phosphate suite of minerals and is probably of an earlier period. The solns. leading to the formation of the foregoing minerals were essentially of Mn phosphate with carbonate and water, Li-rich in the earlier phase and Ca-rich toward the end. A. M. BRANT

Pegmatite minerals of Ontario and Quebec. HUGH S. SPENCE. *Am. Mineral.* 15, 430–50, 474–96(1930).—The minerals occurring in (1) the normal granite pegmatites of Ontario and Quebec and (2) the syenite pegmatites of the Wilberforce district, Ontario, are reviewed and the pegmatites described. The minerals are listed for those of more restricted regional development: (1) the Sn-bearing pegmatites of New Ross, Nova Scotia, (2) mica-apatite-pyroxenite pegmatites of Ontario and Quebec, (3) Li-pegmatites of southeastern Manitoba and (4) granite pegmatites of British Columbia. A. M. BRANT

A remarkable occurrence of thucolite and oil in a pegmatite dike, Parry Sound district, Ontario. HUGH S. SPENCE. *Am. Mineral.* 15, 499–520(1930); cf. *C. A.* 23, 796.—The location is the Besner mine in Henvy township. The pegmatite is a light-pink perthite. The mineral occurred near the dike walls, at or near the surface. It was closely assocd. with radiated groups of a highly altered mineral now chlorite, thought to have originally been pyrorthite. The mineral thucolite occurred in part as well-defined cubic crystals, apparently pseudomorphic after uraninite. Massive material is jet black with a conchoidal fracture and a sooty brownish black streak. Its hardness = 4 and sp. gr. 1.57. The cubes have a dull earthy appearance. Analysis gave:

	Thucolite Crystals	Massive Thucolite
Moisture, 110°.	2.00	1.60
Volatile hydrocarbons	20.19	19.96
Fixed C	50.82	61.56
Ash	26.86	16.63
	99.87%	99 75%

The ash from both samples was strongly radioactive. Minerals found closely assocd. with the thucolite were allanite, beryl, biotite, cyrtolite, garnet, martite, pyrorthite (?), titanite, uraninite. An oily substance was found in 2 parallel fracture zones across the dike. The occurrence of the thucolite indicates that it is not a primary constituent of the pegmatite, and S. suggests that its origin may have been from oil introduced in a later stage. A. M. BRANT

A note on the occurrence of monazite in western Arizona. ROBERT E. S. HERNEMAN. *Am. Mineral.* 15, 536–7(1930).—Scattered pebbles were found in the stream gravels in Mohave county. Some were good crystals, elongated on the b-axis. The sp. gr. of a group of 8 crystals was 5.04. A. M. BRANT

The structure of apatite. I. MARTIN MEHMEL. *Z. Krist.* 75, 323–31(1930).—The dimensions of the hexagonal unit of apatite are: a = 9.36 and c = 6.85 A. U. (±0.02). The space group is C_{6h}^2, and there are 2 mols. of $Ca_5F(PO_4)_3$ in the cell. General positions for all atoms are given, but no parameters. ST. NARAY-SZABO. *Ibid* 387–98(1930)(in English).—A complete detn. has been made by means of abs. intensity measurements. Parameters are given for all at. positions. There are 6 (PO_4) groups in the unit cell; 4Ca ions are on trigonal axes, surrounded prismatically by 6O ions; 6Ca ions are surrounded by an irregular polyhedron of 1F and 5O. F ions are at the corners of the reflection planes, touching 3Ca ions each. L. S. R.

Lazulite from Chittenden, Vermont. CHARLES PALACHE AND F. A. GONYER. *Am.*

Mineral. **15**, 338–9(1930).—The specimen, deep blue in color, is backed by quartzite containing sericite, rutile needles and hematite grains. Soln. of sample for analysis gave 1.49% insol., contg. SiO_2 and probably TiO_2. The sol. material had the compn.: Al_2O_3 33.11, FeO 2.59, MgO 12.38, H_2O^+ 6.24, P_2O_5 46.17, sum 100.49%; formula $(Mg,Fe)O.Al_2O_3.P_2O_5.H_2O$, with Mg:Fe = 8:1. The sp. gr. is 3.08. The optical properties are: biaxial- with 2V = 70°, α = 1.612 colorless, β = 1.634 light blue, γ = 1.643 blue. A. M. Brant

Two phosphates from Dehrn, dehrnite and crandallite. Esper S. Larsen and Earl V. Shannon. *Am. Mineral.* **15**, 303–6(1930).—The 2 minerals were found on a specimen of brecciated phosphorite. *Dehrnite* formed grayish or greenish white crusts of fibrous to bladed crystals. Its phys. properties are: hardness 5, sp. gr. 3.04, fusibility 2, with formation of a white opaque bead, basal cleavage, hexagonal outline. Optically it is uniaxial-, ω = 1.622, ϵ = 1.614. The compn. is: insol. 0.12, CuO 50.88, P_2O_5 37.12, K_2O 1.20, Na_2O 7.11, H_2O^+ 1.52, H_2O^- 0.16, CO_2 1.49, sum 99.60%; probable formula $7CaO.Na_2O.2P_2O_5.H_2O$. *Crandallite* occurs in creamy-white radiating prismatic fibers attached to dehrnite. It is optically +, has a moderate optical angle and has α = 1.59, γ = 1.60. X is parallel to elongation and Z perpendicular to the cleavage (100). It is probably orthorhombic. The compn. is: SiO_2 4.92, Al_2O_3 37.52, P_2O_5 25.24, CaO 11.04, MgO 0.24, H_2O^+ 17.90, H_2O^- 1.00, CO_2 2.54, sum 100.40%; formula $CaO.2Al_2O_3.P_2O_5.6H_2O$. This mineral has previously been called "kalkwavellit." A. M. Brant

The minerals of the phosphate nodules from near Fairfield, Utah. Esper S. Larsen and Earl V. Shannon. *Am. Mineral.* **15**, 307–37(1930).—The nodules were found embedded in a matrix of quartz and calcite. They have an ellipsoidal or discoidal shape and vary in size up to 8 in. The methods used in the study and analysis of the minerals are described. Most of the nodules consisted of a no. of minerals arranged in concentric layers or in part lining or filling cavities. Calcite, variscite, pseudowavellite and wardite were present in most of the nodules. Dehrnite (cf. preceding abstr.) was observed in cavities of the pseudowavellite. Seven new minerals were segregated and studied optically and physically and analyzed. The results are tabulated. Wardite was found to be identical with soumanite. Pseudowavellite is the most abundant mineral in the nodules. The new minerals are *deltaite*, $8CaO.5Al_2O_3.4P_2O_5.14H_2O$; *dennisonite*, $6CaO.Al_2O_3.2P_2O_5.5H_2O$; *lewistonite*, $15CaO.(K,Na)_2O.4P_2O_5.8H_2O$; *englishite*, $4CaO.K_2O.4Al_2O_3.4P_2O_5.14H_2O$; *millisite*, $2CaO.Na_2O.6Al_2O_3.4P_2O_5.17H_2O$; *lehiite*, $5CaO.(Na,K)_2O.4Al_2O_3.4P_2O_5.12H_2O$; *gordonite*, $MgO.Al_2O_3.P_2O_5.9H_2O$. A. M. B.

Scorodite from Gold Hill, Tooele Co., Utah. Wm. F. Foshag, Harry Berman and Ruth A. Doggett. *Am. Mineral.* **15**, 390–1(1930).—The color of the crystals is pea-green. The mineral is optically-; by the Merwin dispersion method the *n*s for D are: α = 1.784, β = 1.796, γ = 1.814; dispersion F-C = 0.3 ± .005. 2V = 54° ± 5°. The mineral is a normal scorodite and at Gold Hill forms bodies of considerable magnitude as an alteration product of arsenopyrite. A. M. Brant

Psittacinite from the Higgins mine, Bisbee, Arizona. Stephen Taber and Waldemar T. Schaller. *Am. Mineral.* **15**, 575–9(1930).—The mineral occurs in coarsely granular masses of anhedral crystals up to 2 cm. diam. with well-defined cleavage in one direction. It is intimately assocd. with higginsite and platy white barite. The compn. is: V_2O_5 21.11, As_2O_5 trace, PbO 50.13, CuO 19.10, ZnO none, ignition loss (H_2O) 4.79, insol. 3.06 (MnO_2), sum 98.19%, approximating the formula $2PbO.2CuO.V_2O_5.2H_2O$ ascribed to psittacinite. The color is dark olive-green, streak yellow. The cleavages show parallel extinction, and the mineral is probably orthorhombic. Approx. values for *n* are α = 2.22, γ = 2.33. The dispersion is strong, $\rho > V$. Thick fragments show distinct pleochroism from yellow to olive-green. The analysis of the mineral from the Higgins mine is compared to that from the Shattuck mine nearby, and the relation to descloizite is discussed. A. M. Brant

Seamanite, a new manganese phosphoborate from Iron County, Michigan. E. H. Kraus, W. A. Seaman and C. B. Slawson. *Am. Mineral.* **15**, 220–5(1930).—The mineral occurs in the Chicagon mine near Iron River, Mich., as small acicular crystals in crevices in a highly ferruginous siliceous rock. A fibrous asbestos-like mineral is assocd. with it. The crystals are transparent, pale yellow, unit prisms terminated by pyramids, with distinct basal cleavage; orthorhombic—bipyramidal, with $a:b:c$ = 0.5195:1:0.4508; hardness 4, sp. gr. 3.128. It is optically + with α = 1.640, β = 1.663, γ = 1.665; X = *a*, Y = *b*, Z = *c* and 2V about 40°. Analysis gave: MnO 56.22, (Mg,Ca)O 1.61, FeO 0.13, B_2O_3 9.95, P_2O_5 16.65, H_2O 14.57%. The mineral is regarded as a double salt of $3MnO.B_2O_3.3H_2O$ and $3MnO.P_2O_5.3H_2O$ in equal proportions. A. M. Brant

Crocoite, lautarite and dietzeite and their crystallographic relationships. B. GOSSNER AND F. MUSSGNUG. *Z. Krist.* **75**, 410–20(1930).—Lattice constants were detd. as follows: crocoite, $a = 6.82$, $b = 7.48$, $c = 7.16$ A. U., $\beta = 102° 33'$, C_{2h}^5, 4 mols. $PbCrO_4$ in cell; lautarite, $a = 7.18$, $b = 11.38$, $c = 7.42$ A. U., $\beta = 106° 22'$, C_{2h}^5, 4 mols. CaI_2O_6; dietzeite, $a = 10.16$, $b = 7.30$, $c = 14.03$ A. U., $\beta = 106° 32'$, 4 mols. The compn. is considered as $CaI_2O_6.CaCrO_4$ rather than $7(CaI_2O_6).8(CaCrO_4)$ as usually stated. The structural and crystallographic relations of these minerals are discussed.
L. S. RAMSDELL

Transparency of gypsum and mica in the ultra-violet. W. HAUSMANN AND O. KRUMPEL. *Strahlentherap.* **35**, 387–90(1930).—Gypsum is highly transparent for ultra-violet rays, which are largely absorbed by mica. B. C. A.

The chemical composition and genesis of the natural iron sulfates. XIV. RUDOLPH SCHARIZER. *Z. Krist.* **75**, 67–87(1930); cf. *C. A.* **22**, 47.—A detailed discussion of the genesis of *römerite*. If free H_2SO_4 is present in an aq. soln. of rhomboclase, hydrolysis is prevented and the acid $H_4Fe(OH)_2(SO_4)_4(H_2O)_6$ is stable. This reacts with $(HO)Fe(H_2O)_6$ to form römerite. A series of analyses of natural and artificial voltaite shows it to be a mixt. of the K Fe^{++} salts of $H_{12}Fe_6(SO_4)_{12}$ + 13Aq and $H_{12}Fe_4(SO_4)_{12}$+18Aq.
L. S. RAMSDELL

Replacement of wolframite by scheelite, with observations on the fluorescence of certain tungsten minerals. FRANK R. VAN HORN. *Am. Mineral.* **15**, 461–9(1930).—A specimen from the East Pool mine, Camborne, Cornwall, England, contains wolframite which is partly or wholly altered or replaced by pinkish scheelite. The alteration seems to have taken place at right angles to the cleavage planes. The scheelite shows a bright blue fluorescence under ultra-violet rays, of a darker shade of blue than other specimens examd. The results of tests made on a series of W minerals are tabulated. It is suggested that the fluorescence of some wolframites and hübnerites is caused by a slight alteration to scheelite. A. M. BRANT

A new iron meteorite from Carbo, Mexico. CHARLES PALACHE AND F. A. GONYER. *Am. Mineral.* **15**, 388–9(1930).—The meteorite, found in 1923, weighed about 1000 lb. The surface is covered with the usual rounded depressions, and in addn. there are a no. of cylindrical holes which are thought to have contained troilite. An etched section shows well-marked octahedral structure. There are numerous nodules of troilite. The bands of kamacite are regular and from 0.5 to 1 mm. thick. The meteorite is classed as a medium octahedrite; its compn. is given. A. M. BRANT

Statistical review of Ontario's mineral industry in 1929. W. R. ROGERS AND A. C. YOUNG. *Ann. Rept. Ont. Dept. Mines* **39**, Pt. I, 1–68(1930). A. H. E.

Quinquennial review of the mineral production of India for the years 1924 to 1928. E. H. PASCOE. *Records Geol. Survey India* **64**, 89–92, 254–7, 318–20, 322–4, 380–3, 384, 385–92, 400–3(1930); cf. *C. A.* **24**, 4245. A. H. E.

The copper shale of Mansfeld. J. W. GREGORY. *Bull. Inst. Mining and Met.* No. **316**, 1–22(1931); cf. *C. A.* **25**, 898.—Discussion. ALDEN H. EMERY

Origin of Copper Mountain (British Columbia) ores. V. DOLMAGE. *Trans. Can. Inst. Mining Met.* **32**, 151–62.—An analysis is given of the ore, which consists of basaltic and andesitic breccia very little altered by mineralization. Possible modes of origin of the ore are discussed; it was probably formed before the magma had solidified to any great extent. B. C. A.

Copper on the Coppermine River, N. W. T. GEOFFREY GILBERT. *Econ. Geol.* **26**, 96–108(1931).—This region in the past has been very inaccessible, but the airplane has revolutionized these conditions. Native Cu, although of widespread occurrence, gives little promise of economic importance, and the chief Cu mineral is the sulfide, chalcocite. Mineralization is apparently confined strictly to the fissures. Resemblances to the deposits of Michigan are obvious, the main difference being in the angle of dip of the flows, which may have a definite bearing on the question of ore deposition. There appears no reason to suppose that the Cu mineralization will be co-extensive with the basalts on the one hand or strictly limited to them on the other. In this district, as in any other, the main requisite is an adequate supply of Cu-bearing solns. Without these, the basalts are no more likely to contain important ore than any other rock; given these, the deposits may occur in other formations as well as in the basalts.
ALICE W. EPPERSON

A quantitative and qualitative determination of the ores of Cobalt, Ontario. JACOB W. YOUNG. *Econ. Geol.* **26**, 112–8(1931).—Y. discusses the recent paper by Ellis Thomson (*C. A.* **25**, 1466). T.s' conclusions as to the pptn. of Ag in the veins at Cobalt, and also for the time of the deposition of the calcite composing the veins in relation to the

metallic arsenides and sulfarsenides, are at variance with previously formulated views which have much to support them. Y. gives data to support these contentions.
ALICE W EPPERSON

Determination of carbon content in carbonaceous pyrite. V. P. ZEMLYANITZUIN. *J. Chem. Ind.* (Russia) **6**, 889–90(1929).—Detns. by 3 different methods were made on a closely bound mixt. of coal and pyrite. All gave practically the same figure of 26.3% C.
A. C. ZACHLIN

Origin of the Manchurian magnesite deposit. HIRONAO NISHIHARA. *Econ. Geol.* **26**, 118–21(1931).—N. discusses a statement made by T. Kato (*Econ. Geol.* **24**, 90–3) as to the origin of the Manchurian magnesite deposit. The conclusion as to whether this deposit is a product of replacement of calcareous rock by Mg of magmatic origin, as Niinomy and Kato conclude, or of sedimentary origin, as N. believes, may have an important economic bearing on future exploration for similar magnesite deposits elsewhere.
ALICE W. EPPERSON

The witherite deposit of the Settlingstones mine, Northumberland. G. TRESTRAIL. *Bull. Inst. Mining and Met.* No. **316**, 23–6(1931); cf. *C. A.* **25**, 899.—Discussion.

Diatomite. PAUL HATMAKER. *Bur. Mines Information Circ.* **6391**, 20 pp.(1931).—H. discusses diatomite under the headings: varieties, occurrence, distribution, properties, uses, mining, prepn., marketing, producers, production, economic condition of the industry and a bibliography of 35 references.
ALDEN H. EMERY

Gypsum. P. P. BUDNIKOV. *Bull. acad. sci. U. R. S. S.* **1930**, No. 77, 1–180.—A collection of the papers published on the above subject by B. and co-workers from 1922 to 1928.
B. C. A.

Salt and gypsum in Alberta. J. A. ALLAN. *Trans. Can. Inst. Mining Met.* **32**, 232–54(1929).—An account is given of the distribution of salt and gypsum in Alberta. They are mostly of Devonian or Silurian age. Interbedding of salt, anhydrite and dolomite in the McMurray deposits shows that they have been deposited at the edge of a sea of varying concn. The anhydrite is of primary origin, but much of the gypsum, occurring as selenite, is secondary.
B. C. A.

The microbiological aspect of peat formation. A. C. THAYSEN. *Fuel in Science & Practice* **9**, 560–3(1930).—Analysis of the behavior of all known types of cellulose-decomposing microörganisms is given as proof that their activity is limited to the very surface layers of peat, that it decreases in intensity under an excess of moisture and that in acid peats it ceases long before the cellulose has been eliminated.
D. A. R.

The present nature of coals resulting from their history. LEON DUBRUL. *Rev. univ. mines* **5**, 10–5, 40–7, 65–77(1931). It is difficult to draw clear-cut conclusions as to the effect of the history of coals on their nature. The single conclusion is that the causes of differentiation are many. The evolution of the coal beds is as follows: The peat formed had a variable chem. compn. depending on the nature of the plants and especially on their manner of decompn. and consequently on the rate at which the peat bogs sank. According to the wt. of the overlying material the mass underwent an anthracitization, the modality of which depended upon the initial state; this mass, then under equal pressure and time, showed what is termed the "original differentiation," consisting in a localization of varieties richer in volatile matter in the zone where the subsidence was quickest. But if the overburden varied in thickness, it could have modified the differentiation and at times might have had the reverse effect (Gard). At the same time, under the influence of the variable load there was produced a vertical change by a decrease in volume, relatively greater for lower beds (Hilt's law). At the time of folding the influence of static pressure became negligible as compared with dynamic pressure. Orogenic forces were the cause of a new lateral differentiation, because the quantity of energy transformed into heat depended upon the resistance to the lateral thrusts. It was thus that the regions displaced did not become thinner, the rubbing having been solely a source of heat (Serang); the masses that had been crushed against a resistant block for the most part lost energy, from folding, in heat and underwent an intense devolatilization (Herstal). The depth of the bed had only a min. influence on the coals already formed. Four differentiations are: (1) original; (2) by wt. before folding; (3) through orogenic forces; and (4) by wt. after folding. The first and third are generally the most important; the second is found occasionally, and the last relatively seldom.
C. W. OWINGS

Igneous intrusions and ore deposits of the zone of flowage. E. C. ANDREWS. *Econ. Geol.* **26**, 1–23(1931).—The igneous rocks of the Willyma or Broken Hill "older-

mass" belong to 2 periods of intrusion: that of marked folding, and that of relative stability. The ore deposits are phases of igneous intrusions belonging to the closing stages of the "bedded" form. All the ore deposits examined appear to end vertically as well as laterally, either against or between bedding planes. No sign of feeding source has been detected for the igneous rocks. A. infers that the Broken Hill region during the earlier portion of pre-Cambrian time was affected by a movement of strong folding, in which there was a strong reaction toward the surface of the earth. Field study suggests that the igneous rocks and the ore deposits may not contain the same mineral assemblages which they possessed during their passage to the "pressure-slacks." The latest stages of igneous intrusions appear to have been attended with increased mobility of the igneous material, resulting in injection and replacement, both of sediments and the earlier orthogneisses, by aplite, pegmatite and ore deposits. A. W. E.

Structural geology of the Conception Bay region and of the Wabana iron ore deposits of Newfoundland. ALBERT O. HAYES. *Econ. Geol.* **26**, 44–64(1931).—A table of formations is given, and stratigraphy and structural geology of the region is discussed. The limits of the Fe ore are fixed by faults, and the northern limits of the ore are thought to be along a fault line from Colliers Bay to the middle of Conception Bay. The Fe ore reserves are discussed, and it is estd. that mining operations may continue on a scale limited only by the amt. the market will absorb and the engineering difficulties of submarine operations. ALICE W. EPPERSON

Southern contact of the Riesen Mountain granite and the adjacent slate region. ADOLPH WATZNAUER. *Lotus* **78**, No. 2, 112–64(1930).—A petrographical study. W. L. HILL

Differentiation in the Cape Spencer flow. RICHARD J. LUND. *Am. Mineral.* **15**, 539–65(1930).—This is the thickest and lowest of a series of 5 Triassic lava flows found on Cape d' Or, Nova Scotia. The optical study was made on material from a drill core. The variations in mineral content, in the FeO:MgO ratio, and in the optical properties of the pyroxene and plagioclase series are given in the form of tables and graphs. Differentiation of the type known as fractionation took place during the crystn. of the flow. This was brought about by the fractional crystn. of the plagioclase and pyroxene series together with the relative movement of these minerals with respect to the liquid. A. M. BRANT

Differentiation in the Dartmoor granite. A. BRAMMALL. *Nature* **126**, 132(1930).—Graded and significant variations in the chem. compn. of granites from East Dartmoor are discussed. B. C. A.

Eruptive rocks of the Oberwiesenthal, Erzgebirge. R. HERRE. *Chem. Erde* **4**, 632–65(1930).—Petrographical descriptions with chem. analyses are given of phonolites and basalts from this locality in Saxony. B. C. A.

Geology of the south coast of New South Wales. III. The monzonitic complex of the Mount Dromedary district. IDA A. BROWN. *Proc. Linnean Soc. N. S. Wales* **55**, 637–98(1930).—Tables of complete chem. analyses of many specimens of the rocks are given. The igneous complex is intrusive into metamorphosed sediments of early Paleozoic age, the main intrusion being an outcrop over an oval area of about 25 sq. mi., probably in laccolithic form. The igneous complex consists of plutonic and hypabyssal types. A study of the field occurrence and assocns. of these igneous rocks and of their mineralogical and chemical compns. shows that probably they are all comagmatic, but that the degrees of consanguinity of the different groups vary. B. considers that the main monzonitic series composing the laccolith has been produced as a result of the differentiation of a monzonitic magma in place, by means of fractional crystn. and the sinking of crystals. The origin of the garnet-bearing series is more obscure; it may be due to secondary differentiation of a basic phase of the magma, or the result of assimilation of limestone by the monzonitic magma, with subsequent differentiation. Direct evidence of the age of the intrusion is scanty, but the chem. similarity of the series as a whole to the monzonitic rocks of Milton and the latitic flows of the Illawarra District indicates a probable Permo-Carboniferous age. ALICE W. EPPERSON

The iron-rich norite at Akkavare (Sjaunja). PER GEIJER. *Geol. Fören. Förh.* **52**, 391–7(1930).—Varieties of norite rich in Fe have been discovered at Akkavare, Sjaunja. The rock is generally massive, dark and with the size of the grain averaging 1 to 2 mm. for the main constituents. Five specimens are described in detail. The magnetite and ilmenite content varies from 10.7 to 28.8% by vol. in the different specimens. WILHELM SEGERBLOM

Lamprophyrite of the petrographical province of Predazzo. SILVIO VARDABASSO. *Ann. scuola ing. Padova* **4**, 195–216(1928).—In the eruptive territory of Predazzo and

Monzone, the stratigraphical series and the volcanic rocks are crossed by numerous dark veins. These may be put into 2 classes: (*a*) non-differentiated veins related to porphyrite and melaphyre traversing all sedimentary rocks remaining in the district (Triassic period), tuffs and lava but not the intrusive masses, (*b*) veins differentiated by the continuation of intrusive masses (monzonite, etc.); these are the most recent of all rocks in this part of the Dolomites. The latter basic series, or lamprophyrites, contain in turn many types considered as representing an alk.-calcareous magma (pacific) and others an alk. magma. This is one of the most salient characteristics of this petrographical province. V. gives 4 figures illustrating the compn. of camptonite, 3 for monchiquite, 4 for rizzonite, with a table of compn., and 2 for lamprophyrite with 3 analyses. There is a bibliography of 34 references. S. L. B. ETHERTON

Water content and degree of compactness of argillaceous rocks. W. PETRASCHEK AND B. WILSER. *Berg. Hüttenm. Jahrb.* **74**, 57–65(1926).—The water content, other than that evolved at a red heat, diminishes with increasing metamorphism. B. C. A.

The mineralogy of some deposits of kaolinized volcanic ash from the slate belt of North Carolina. JASPER L. STUCKEY. *Am. Mineral.* **15**, 253–8(1930).—The deposits described lie in areas of acid volcanic rocks. Quartz, altered feldspar, sericite, kaolinite, epidote, rutile, titanite, hydromica, and halloysite were identified by microscopic means, while much fine-grained material could not be identified. Screen tests and chem. analyses of the material are given. The origin of the deposits was fine-grained tuff or volcanic ash. In the northern part they have been changed by severe metamorphism to sericite schist, and in the south have weathered to impure kaolin. A M. B.

Mechanical analyses of sediments by centrifuge. PARKER D. TRASK. *Econ. Geol.* **25**, 581–99(1930).—An application of the centrifuge to the procedure of mech. analyses of sediments on the basis of Stokes' law is described. The method consists in decanting the sand and detg. the rate of increase in wt. of finer particles settling out, with time. This is done by sepg. the suspension contg. these finer constituents into a no. of aliquots and detg. wt. of material that settles from each aliquot after centrifuging for definite times and at specified speeds. Curves representing the rate of fall are constructed by plotting the wt. of sediment that settled from the aliquots against the proper values for the time. From these curves, both the size distribution of the constituents and the percentile diams. are readily obtained. Chief advantages of the method are: it is rapid and does not involve complicated app.; it permits of presentation of the results as percentile diams.; and it gives the complete size distribution of the constituents down to any desired dimension, no matter how small. A. W. E.

Sedimentation in the Channel Islands region, California. PARKER D. TRASK. *Econ. Geol.* **26**, 24–43(1931).—The mech. compn. of the deposits of this region varies with the configuration of the ocean bottom. Finer sediments accumulate in the basins and coarser on the divides, topography influencing sediments more than depth of water or distance from shore. Finer deposits of the Pacific Coast region are more coarse-grained than corresponding sediments forming off master streams, such as Orinoco, Mississippi or McKenzie. The $CaCO_3$ content of sediments is variable, but in general less in shallow water than in depressions, where it reaches a max. of 16%. The org. content varies with bottom configuration and ranges from less than 1 to 7% in deposits in the bottom of Santa Cruz basin. Ignition loss is a rough index of the amt. of org. matter. The C-N ratio of recent deposits does not vary greatly from 8.4. Consequently, the org. content of sediments may be estd. by multiplying the percentage of N by 14. Sediments of past geologic age contain about half as much N with respect to C as do recent deposits. ALICE W. EPPERSON

Subterranean water conditions in the coastal regions of the Netherlands. J. VERSLUYS. *Econ. Geol.* **26**, 65–95(1931).—Geologic history of the area is given, and the character of the deposits and their influence on ground water are described. Chem. action in the subsoil of the dunes is discussed. Formation of water with excess of alkalies is explained by assuming that the sea-water has ceded alkalies to the soil, and that these, when the sea-water was displaced by calcareous fresh water, have in turn been exchanged for Ca. ALICE W. EPPERSON

Iron and manganese hydroxide sols in relation to the black coating on rocks and the formation of laterite. W. KNAUST. *Chem. Erde* **4**, 529–48(1930).—Sols of the hydroxides were prepd. with H_3PO_4 as a peptizing agent, and various expts. were made to det. the conditions for their coagulation. The bearing of these expts. on the deposition of Fe and Mn oxides as a coating on rocks and on the formation of laterite is discussed. B. C. A.

Soils derived from the glacial boulder-marl in the Hamburg district. E. SCHMIDT. *Chem. Erde* **4**, 475–500(1930).—Detns. of the amt. of $CaCO_3$, of the size of particles,

and of the heavy minerals present in the boulder clay and the overlying soils are recorded. B. C. A.

Annual review of Swedish geological literature for 1929. R. SANDEGREN AND M. MAGNUSSON. *Geol. Fören. Förh.* **52**, 689–754(1930).—Continuation with 190 titles of the résumés described in *C. A.* **23**, 1598; **24**, 1605. WILHELM SEGERBLOM

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, H. W. GILLETT AND RICHARD RIMBACH

What the Bureau of Standards does for metallurgy. RICHARD RIMBACH. *Metals and Alloys* **2**, 65–70(1931). A. J. MONACK

Principal metallurgical products utilized in aeronautical construction. G. R. HAMEL. *Aciers spéc.* **5**, 550–8(1930). A. J. MONACK

Progress of metallurgy at Broken Hill, N. S. W. M. R. MCKEOWN. *Chem. Eng. Mining Rev.* **23**, 93–100(1930).—The equipment, operation and reagents used are described. Slow-speed crushers and vibrating screens are preferred. An all-flotation treatment with an alk. current of 0.005% Na_2CO_3 is used. This process yields higher-grade Pb and Zn concentrates, low time factor for flotation and lower costs. A. N. H.

Quinquennial review of the mineral production of India for the years 1924 to 1928. E. H. PASCOE *Records Geol. Survey India* **64** (1930).—**Introduction.** *Ibid* 1–3. **Summary of progress.** *Ibid* 4–25.—Detailed production figures for Indian minerals from 1924 to 1928 are given. **Antimony.** *Ibid* 26–8.—Stibnite lodes in gneissose granite occur in Punjab. They carry 6 dwts. of Au per ton. Stibnite with cervantite occurs in the Northern Shan states. The tetrahedrite in the Sleemanabad Cu lodes is highly antimonial. About 1000 tons per yr. of antimonial Pb, analyzing Pb 77, Sb 21% and Ag 6–8 oz. per ton, is produced in Burma. **Copper.** *Ibid* 78–88.—In Singhbhum, Cu lodes occur in muscovite and chlorite-quartz-schists. At the surface they consist of quartz with malachite, chrysocolla and red oxides of Fe contg. small quantities of Cu, possibly as red oxide, with sometimes small incrustations of liebethenite In depth the ore is entirely chalcopyrite. There is a small chalcocite zone not far below the surface. In the Darjelling area, chalcopyrite occurs disseminated through slates and schists. Recent work has shown lodes in Sikkim in which Cu is assocd with Bi, Sb and Te. Tetradymite and linnaeite are found. Typical minerals are chalcopyrite, pyrite, pyrrhotite, sphalerite and galena. Several occurrences are described. Bawdwin (Burma) ore analyzed Pb 13, Zn 8, Cu 7% and Ag 18 oz. per ton **Arsenic.** *Ibid* 320–2.—The chief Indian source of As is the orpiment mines of Chitral, where realgar, orpiment and fluorspar occur. **Bismuth.** *Ibid* 344.—Native Ni and bismuthinite occur in wolfram and cassiterite-bearing veins of lower Burma. **Cobalt.** *Ibid* 379–80.—Cobaltite and danaite have been found disseminated among certain slates. The Ni speiss of the Burma Corp. contains 3–4% Co. **Nickel.** *Ibid* 412–3.—Nickeliferous pyrrhotite, chalcopyrite and pyrite occur in various parts of India. It is a by-product in the smelting operations of the Burma Corp. ALDEN H. EMERY

Quinquennial review of the mineral production of India for the years 1924 to 1928. Iron. H. CECIL JONES. *Records Geol. Survey India* **64**, 111–46(1930).—Bihar and Orissa are the only parts of India where Fe ore is mined for the production of Fe and steel. In Burma limonite and hematite are produced for use as a flux in Pb smelting The main plants are described and analyses given of their raw materials and finished products. Ore occurrences are also described in detail. ALDEN H. EMERY

The concentration of ores by flotation. H. L. SULMAN. *Bull. Inst. Mining and Met.* No. **316**, 31–6(1931); cf. *C. A.* **24**, 2699, 5006, 5263; **25**, 901.—Discussion. ALDEN H. EMERY

Water concentration tests. BERNARD W. HOLMAN. *Bull. Inst. Mining and Met.* No. **316**, 29(1931); cf. *C. A.* **24**, 2699; **25**, 901.—Discussion. ALDEN H. EMERY

Reduction of iron oxide ores in molten state by means of hydrogen and other gases. SAMUEL L. MADORSKY. *Ind. Eng. Chem.* **23**, 99–103(1931).—Thirteen expts. were undertaken to reduce molten Fe oxide with H_2, water gas and CO. For each kg. of Fe 1.19 cu. m. of H_2, 45% of the theoretical, was required. An Fe product is obtained at a cost comparable to that of other steel-making processes. C. H. LORIG

Leaching copper ores: advantages of wet-charging. JOHN D. SULLIVAN AND ALFRED P. TOWNE. Bur. Mines, *Rept. of Investigations* 3050, 26 pp.(1931); cf. *C. A.* **25**, 478.—Charging the ore into the leaching vat in the wet condition increases the extn. of Cu. Virtually identical extn. was obtained by upward and downward percolation when the solns. were not continuously circulated. In the latter case, extn. was greater on downward percolation. Virtually identical extn. resulted from flood and trickle leaching when the ore was wet charged. With dry-charged ore, extn. was greater from +100-mesh ore than from unsized material contg. fines; there was no difference when the ore was wet charged. ALDEN H. EMERY

Cyanidation of a copper-gold ore. E. H. SMITH. *Can. Chem. Met.* **15**, 45–6 (1931).—The function of lime in cyanidation of Au ores is attracting much attention. Lime and alky. have no solvent action on the precious metals, but enter into numerous reactions occurring in the process. A pyritic ore ground in lime soln. yields CaS and CaS_2O_3, and gang constituents consume a certain amt. of lime. Each mineral in an ore removes lime from the mill soln. in an amt. dependent on the lime present, and this amt. is sp. for each mineral. Lime decomposes the $Zn(CN)_2$ or double cyanide formed in the pptn. processes. W. H. BOYNTON

Method and cost of recovering quicksilver from low-grade ore at the reduction plant of the Sulphur Bank Syndicate, Clearlake, Calif. WORTHEN BRADLEY. Bur. Mines, *Information Circ.* **6429**, 17 pp.(1931).—The ore deposit consists of grains of cinnabar finely disseminated throughout a gang composed principally of altered basalt with subordinate amts. of elemental S (1–15%, av. 2%) and opal. Recovery is as follows: (1) screening (cinnabar mostly in fines) and sorting the low-grade ore to obtain a furnace feed contg. 8–10 lb. Hg per ton, (2) treatment in a rotary kiln, (3) pptn. of dust from gas stream, (4) condensing Hg from gas, (5) flotation of low-grade condenser mud and (6) retorting high-grade condenser mud and high-grade flotation concentrates. Costs per ton of ore treated for April, 1930, are: screening and sorting $0.835, furnace treatment $1.709, flotation $0.387, retorting $0.177, assaying $0.107, condensing $0.534, miscellaneous $0.359 and total $4.108. ALDEN H. EMERY

Milling methods and costs at the Homestake Mine, Lead, S. D. ALLEN J. CLARK. Bur. Mines, *Information Circ.* **6408**, 25 pp.(1931).—The ore bodies occur in altered dolomitic limestone contg. cummingtonite and chlorite with pyrite, arsenopyrite and pyrrhotite. The Au content is about $5.00 per ton of ore. Amalgamation recovers 62.8% of the Au (chiefly coarse), cyanidation of sand 20.6%, and cyanidation of slime 9.6% more, a total of 93% recovery. Cost of crushing in mine and at hoists in 1929 was 3.8 cents per ton, milling 27.6 cents and cyanidizing 18.9 cents, a total of 50.3 cents per ton of ore milled. Detailed metallurgical data and costs are given. A. H. E.

The Roan Antelope mill and smelter. A. G. MCGREGOR. *S. African Mining and Eng. J.* **41**, pt. 11, 373–4(1930). ALDEN H. EMERY

Lead smelting in shaft furnace with zinc-rich slags. KARL PRIOR. *Metall u. Erz* **28**, 25–33(1931).—High Zn content is unfavorable for operation of the shaft furnace. The constitution of shaft-furnace slags in general is discussed, as well as the forms in which Zn is found in the slag. Among these are the oxide, silicates, Zn spinel, Zn ferrites, zincates and sulfides. Operating conditions in the presence of high Zn content are discussed. H. STOERTZ

Copper and zinc in cyanidation sulfide-acid precipitation. EDMUND S. LEAVER AND JESSE A. WOOLF. Bur. Mines, *Tech. Paper* **494**, 63 pp.(1931).—All of the common Cu minerals except chrysocolla and chalcopyrite are sufficiently sol. in cyanide soln. to cause excessive reagent loss (2–3 lb. NaCN per lb. Cu) unless the cyanide combined with the Cu is regenerated. The Na_2S-H_2SO_4 method regenerates an av. of > 80% of the cyanide from solns. used to treat precious-metal ores contg. up to 0.5% cyanide-sol. Cu. Solns. used to treat cuprite or metallic Cu give large regeneration. The more complex the Cu mineral treated, the less cyanide will be regenerated from the resulting soln. The more nearly all the cyanide is combined with Cu and the less the cyanide is uncombined (free) the greater will be the regeneration. The amt. of Na_2S used varies with the amt. of metals pptd. The acid consumption varies with the strength of the original soln. in both cyanide and lime. The Ag may be pptd. separately from the Cu before the soln. is acidified. The CuS must be removed from the acid soln.,

as it redissolves in alk. cyanide soln. Only a small quantity of Au is pptd. by the Na_2S-H_2SO_4; most must be removed by Zn as usual. Cu in cyanide soln. up to 10 lb. per ton does not diminish the activity of the soln. as a solvent for Au and Ag if the requisite free cyanide is present. The double Na-Cu cyanide soln., in the absence of free cyanide, is only a weak solvent for the precious metals and is more effective for Au than for Ag. Smithsonite, hydrozincite, zincite and calamine are sol. enough under the usual conditions of cyanidation to cause rapid accumulation of Zn in the soln. unless special precautions are taken to remove it. Willemite, sphalerite and franklinite are dissolved more slowly. From 1.5 to 4.0 lb. NaCN is needed per lb. Zn dissolved. The various Zn cyanide compds. are only weak solvents for the precious metals, even if $AgNO_3$ titration shows free cyanide. Addn. of excess CaO or caustic soda improves extn. by liberating free cyanide from the double salt. If most of the cyanide present in a soln. is combined with Zn, more free cyanide must be added to this soln. than to a fresh soln. for the 2 to have = activity as solvents. Na_2S-H_2SO_4 treatment will remove Zn and regenerate cyanide. When ores contg. sol. Zn minerals are treated, the soln. must contain free cyanide, or the soln. of Zn will decrease Ag extn. The Welch method was thoroughly tried and seems to apply only to Au ores or to Au-Ag ores contg. not over 0.1% of cyanide-sol. Cu and in which Ag occurs as a haloid mineral. A. H. E.

Recovery of zinc from ferrite compounds in the electrolytic zinc process. G. L. Oldright and D. P. Niconoff. Dept. Mining and Met. Research, Univ. of Utah, *Tech. Paper* **6**, 45 pp.(1929).—Zn ferrite formation increased with increasing time, temp. and fineness. Fe in Zn ferrite was more readily sol. than when present in Fe_2O_3. Replacement of ZnO in ferrite by other bases such as CaO and MgO is possible but not practical. Zn ferrite was readily decompd. by treatment with reducing agents at elevated temps.; Zn was then sol. in NH_3 or H_2SO_4. High concns. of reducing gases make the Fe sol. in H_2SO_4. C will reduce ferrites at 800°. Pure CO should not be used below 600°, as CO_2 is needed at low temps. to prevent its decompn. to CO_2 and C. The best procedure was treatment for 2 hrs. at 550° with CO_2 contg. 35–50% CO. This makes 80% of the Zn and 39% of the Fe sol. in H_2SO_4. To make more Zn sol., higher proportions of Fe were dissolved. The rate of decompn. of ferrite with reducing agents, as well as its rate of soln. in H_2SO_4, HCl and HNO_3, depends upon the temp. and time of prepn. of the ferrite. By giving refractory ferrite a preliminary low-temp. roast, the subsequent rate of reduction can be increased. Alden H. Emery

Purifying zinc by dry method. D. M. Chizhikov. *Mineralnoe Suir'e i Tzvetnuie Met.* **4**, 1211–8(1929).—The processes of purifying Zn are described briefly. M. A. J.

Memorandum on calcination of zinc carbonate ores in particular in a continuous-charged furnace (Jalabert method). Gustave Piron. *Rev. ind. minérale* No. **241**, 9–14(1931).—By eliminating the moisture and CO_2, the wt. is decreased 25–32%, according to the ore. The beneficiation of the ore increases its salability. However, calcined ore has to be kept covered in transportation and in storage. Lean calamines are calcined either in an ordinary reverberatory furnace or in an Oxland or Spirek furnace. Best results from calcining are obtained in a shaft furnace, but lean ores cannot be treated in this furnace. The Jalabert furnace, designed to treat this class of ores with the advantages of the shaft furnace, is constructed of brick; ordinary bricks are used as high as the inlet air holes, and the upper part is made of a shell of refractory brick. Ventilation is induced by a blower. In calcining, the lean calamines are mixed first with a combustible in a proportion detd. by lab. tests. At Gustar, wood-charcoal dust is used in the proportion of 9% by wt. of the raw ore. The yield of calcined material varies from 68 to 73%. Calcination of Zn carbonate in the Jalabert furnace takes place under relatively the same conditions as in a shaft furnace and has the following advantages: (1) good utilization of inferior quality combustible that consequently reduces costs; (2) inexpensive construction and installation; (3) reduced labor, (4) continuous operation; and (5) perfect calcination. C. W. Owings

A consideration of some of the problems of the chloride volatilization process. Robert H. Bradford and Carrol Max Macfarlane. Dept. Mining and Met. Research, Univ. of Utah, *Tech. Paper* **3**, 21 pp.(1928).—$CaCO_3$ was increasingly deleterious to chloride volatilization as its content in the gang of an ore increased above 20%. Water vapor was beneficial when treating ores with a high calcareous gang. HCl was a more active chloridizer than $CaCl_2$ or NaCl. HCl was prepd. by spraying a soln. of $CaCl_2$ or NaCl into the roasting furnace, SiO_2 being necessary with NaCl. An oxidizing atm. contg. 4–11% O_2 was best when chloridizing a Cu ore. A. H. E.

Recovery of noble metals from waste. A. Ievinš. *Acta Univ. Latviensis, Kim. Fakult. Serija* **1**, No. 1, *Burtnica*. 1–11(in German **12**)(1929).—Smelting gives better results than the Cl or CN processes for 1–3% content of noble metal, the efficiency

increasing with the richer charges. The yield is increased by adding $CaCO_3$ and $MgCO_3$ and holding for sufficient time at 1350–1400°. ANN NICHOLSON HIRD

Platinum. PAUL M. TYLER AND R. M. SANTMYERS. Bur. Mines, *Information* 6389, 69 pp.(1931).—The following subjects are discussed for Pt: properties, uses, alloys, substitutes, history, ores and minerals, occurrence (U. S. and foreign, by states and countries), assaying, mining, concg., refining, production, marketing and prices. *Osmiridium* is briefly discussed. ALDEN H. EMERY

Fluxes for brass melting. E. T. RICHARDS. *Giesserei-Ztg.* 27, 433–5(1930).—Fluxes used in brass melting serve 3 purposes: they accelerate the melting process; they protect the metal from oxidation; and they remove impurities. Glass and sand mixts. are the common com. fluxes, used often with covers of charcoal, coke and NaCl. In crucible melting, borax is used to dissolve SiO_2, Al_2O_3., CaO, etc., and to lessen the Zn loss. Mixts. of boric acid, borax and the alk. carbonates are strongly desulfurizing. Boric acid is gradually displacing borax as a flux, in spite of its higher cost. Potash and soda are used to remove S and As. $KHSO_4$ is valuable for removing Al, but it introduces a little S into the brass. For the removal of Fe, the brass is treated with a mixt. of 75% calcined soda, 18% KCN and 7% powd. glass. For Pb-rich alloys, mixts. of talc and quartz are recommended. CURTIS L. WILSON

Manufacture of wire bars from secondary copper. P. SIEBE. *Giesserei-Ztg.* 27, 505–9(1930); cf. *C. A.* 23, 4915. CURTIS L. WILSON

The production of high-test cast iron. II. RICHARD MOLDENKE. *Iron & Steel Can.* 14, 27–8, 41–2(1931); cf. *C. A.* 25, 1192. E. H.

Processing 3-ton wrought-iron balls. A new departure. J. D. KNOX. *Steel* 87, No. 20, 43–6(1930).—The Aston process for making wrought iron and the new plant of the A. M. Byers Co. near Pittsburgh, Pa., are described. LESLIE B. BRAGG

The reductivity of over-crusted coke and the production of a carbon-poor forgeable channel iron in the foundry shaft furnace. E. PIWOWARSKY. *Die Giesserei* 17, 1149–52 (1930).—Expts. to det. the effect of impregnating coke with milk of lime on its reactivity. Thus, a current of CO_2 is allowed to react with coke at 900° and 1100°, and the amt. of CO formed is detd. These expts. show that when coke is satd. with milk of lime CO is formed in greater amt., the reductivity of the coke being actually favored by the impregnation. Claims in the patent of June 2, 1919 (class 18a, Gr. 3, C. 38 289) are disproved. Low-C Fe (1.6% C and less) has successfully been prepd. by P. in the cupola furnace. J. BALOZIAN

Agglomeration of blast-furnace dust and treatment of iron carbonate minerals by the Greenawalt process. ROBERT CORDONNIER. *Rev. Metal.* 27, 467–78(1930).—A description of plant operations and the process for sintering blast-furnace dust and Fe carbonate ores are given. C. H. LORIG

Deoxidation of steel with silicon. C. H. HERTY, JR., G. R. FITTERER AND C. F. CHRISTOPHER. Bur. Mines, *Tech. Paper* 492, 42 pp.(1931).—The liquidus of the system FeO–SiO_2 has been studied over the range 45–100% FeO. The m. ps. of synthetic Fe^{++} silicates were detd. with the micropyrometer. Fayalite ($2FeO.SiO_2$) melted at 1335°. Two eutectics, at 65 and 78% FeO, were found; their m. ps. were 1260° and 1240°, resp. The deoxidation const. for the reaction $2FeO + Si \rightleftharpoons SiO_2 + 2Fe$ was detd. to be $K_D = (Si)(FeO)^2 = 1.65 \times 10^{-4}$ when all concns. are expressed as wt. %. Fluxing of SiO_2 by dissolved FeO was shown to be an important factor in the deoxidation of low-C steel. Steels high in SiO_2 are red-short in forging, while steels contg. Fe^{++} silicates high in FeO forged without cracking. The use of Si as a deoxidizer in steel-making processes always results in the formation of SiO_2 or silicates, depending on the amt. of Si used and the concurrent use of other deoxidizers. If Si is used alone, the SiO_2 formed is extremely hard to eliminate. The oxidation of the metal in the basic open-hearth process increases as the C content decreases. The time required to eliminate silicates, resulting from deoxidation with Si, from the steel bath was proportional to the depth of the bath and inversely proportional to the size of the particles formed on deoxidation. Agitation of the bath assisted in cleaning it. High residual Mn had only a slight cleaning effect. Segregation of silicates in ingots from 20 lb. to 3 tons in wt. was studied. In top-poured steels the max. segregation was in the center of the ingot about 15% from the bottom. An annular zone of high-silicate segregation was found in the upper portion of these ingots and is due to crystn. phenomena. In bottom-poured ingots segregation is more irregular and is complicated by erosion of runner brick. ALDEN H. EMERY

Operation and metallurgy of a 200-ton tilting furnace for the Talbot process [of steel making]. W. ALBERTS. *Stahl u. Eisen* 51, 117–28(1931).—In continental practice, open-hearth furnaces for steel making are considered economical up to 75–100 tons

capacity. For larger sizes tilting furnaces are more economical because of the easy removal of the slag by tilting the furnace. The construction and the operation of a 200-ton tilting furnace, which can be used for either the scrap iron or the pig iron-ore (Talbot) process, is described in detail. In using the scrap iron process best results were obtained by tapping off $^3/_8$ of the content of the furnace at the end of the melt, while in using the Talbot process the most economical operation was attained by tapping off only 65–75 tons. The chem. reactions during the melting process were followed by taking samples from the melt from various depths. About 3 hrs. was required to obtain the steel of the desired compn. For deoxidation Fe-Mn gave better results when added as a liquid rather than as a solid. The mech. tests carried out on a great no. of melts showed that the steel obtained by the Talbot process was of a very good quality. Many references are given. J. A. SZILARD

Graphical calculation of cupola furnace mixtures with special regard to pearlite castings. BÉLA SZÖKE. *Die Giesserei* **17**, 1013–7(1930).—A theoretical paper in which is described a method using parallel coördinates for detg. the wt. of each constituent to be charged into a cupola furnace to obtain a given content of a given element (*e. g.*, Ni) in the Fe drawn-off. The charged mixt is prepd. from 2 or 3 kinds of Fe, with known Si content. Three examples showing the application of the method to various charges (2 pearlitic castings) are given. J. BALOZIAN

The method of running the Buess "rocking revolving" furnace. WILHELM BUESS *Die Giesserei* **17**, 1121–2(1930).—A brief description is given of the Buess furnace for mixing various alloy mixts. by revolving off-center. The furnace is also suited for the production of high-quality cast Fe; it is provided with a device for observing the smelting process and for drawing-off samples without disturbing the melt. When revolving at a speed of $^1/_2$ revolutions per min., the melt is thoroughly mixed and well degassified, and the thermal efficiency of the fuel is high. The furnace burns either gaseous, liquid or powd. fuels. J. BALOZIAN

Kinetic measurments of transformation reactions in solid metals. W. FRAENKEL AND E. WACHSMUTH. *Z. Metallkunde* **22**, 162–7(1930).—The decompn. of an alloy of 80% Zn and 20% Al as a result of the transformation occurring at 260° was studied by means of an especially sensitive dilatometer. The velocity of the decompn. is expressed in terms of length (vol.) changes as a function of time. It is found that the decompn. in a quenched alloy near 0° begins at a very low rate, then auto-accelerates and finally comes to completion. The velocity is greatly dependent upon the quenching temp.: the higher this temp., the lower the velocity. An attempt is made to derive an equation expressing the vol. of the reaction. The elec. cond. in quenched alloys first increases and then decreases. The elec. cond. curve over the temp. range 200–360° shows variations at the transformation point, the meaning of which is somewhat uncertain, appearing most nearly like points of inflection. The effect of cold-working on the density and electrical resistance of metals. TARO UYEDA. *Science Repts. Tôhoku Imp. Univ.* **19**, 473–98(1930).—When cold working consists of rolling or drawing, the internal stress cannot be measured. In these expts. the tensile stress applied to test pieces of Swedish steel, Cu and brass was made in an Amsler testing machine. The elec. resistance, elongation and reduction in area were measured at const. temp., and the changes in d. and in sp. elec. resistance were calcd. The d. decreased in proportion to the stress up to the yield point, after which it decreased more rapidly. The sp. elec. resistance increased in proportion to the stress up to the yield point, after which the Cu and brass showed more rapid changes than the steels. The rate of change of sp. resistance decreased with increasing C content. The decrease in d. is attributed to an elastic origin up to the yield point; beyond this point it is attributed to minute cavities formed by internal slippings in the

metal. The increase in elec. resistance is attributed to the same cause above the yield point; below the yield point the increase is explained by the diminution of free electrons, which have become bound electrons around a nucleus caused by enlarging the space lattice. CURTIS L. WILSON

What is this thing called fatigue? H. W. GILLETT. *Metals and Alloys* **2**, 71–9 (1931).—Review. A. J. MONACK

Some notes on blue brittleness. LELAND R. VAN WERT. Am. Inst. Mining Met. Eng., *Tech. Pub.* No. **404**, 11 pp.(1931).—Stress-strain diagrams of low-C steels tested between 200° and 350° depart from the normal regularity of such diagrams secured by testing above or below this range. Under a uniformly increasing load, deformation does not proceed regularly. Periods of deformation alternate with periods of little yielding. This 3-stage cycle continues until fracture ensues. The relative lengths of the periods increase as loading proceeds. It is now believed that aging after overstrain and blue brittleness are the same phenomenon. An effect of aging after overstrain is recovery of the elastic limit. At 250° this aging may produce as complete recovery in a few sec. as in 2 weeks at ordinary temps. Aging after overstrain and blue brittleness are the result of dispersion hardening. High-purity Fe gave a decidedly irregular curve at 300°, but without the sharp steplike characteristics usually obtained from steel or Fe contg. more impurities. It is believed that the recovery of elasticity on aging is more apparent than real, and that aging after overstrain affects the elastic properties of ferrite not by actual restoration of the true elastic limit, but by producing through dispersion hardening an effect that simulates recovery. When the apparent recovery becomes instantaneous at blue-heat temps., as with ferrite solns. with usual concns. of dissolved hardeners, or at lower temps. where high concns. result in a greater metastability, the stress-time diagrams take on the steplike character noted. H. C. PARISH

Directional properties in cold-rolled and annealed copper. ARTHUR PHILLIPS AND E. S. BUNN. Am. Inst. Mining Met. Eng., *Tech. Pub.* No. **413**, 18 pp.(1931).—In order to avoid serious directional properties in Cu, it appears desirable to limit the final reduction to 50–60% and the final anneal to 500–600°. It is believed, however, that the preliminary history of the material has considerable bearing on the problem. There is reason to think, for instance, that if the last annealing temp. were 800° instead of 550°, directional properties of a different nature and order would be encountered. H. C. PARISH

A new etching reagent for nitrided layers. O. HENGSTENBERG AND F. BORNEFELD. *Krupp. Monatsh.* **11**, 265–6(1930).—The new etching method proposed consists first of brief treatment with a soln. of 1 g. HgCl in 20 cc. of concd. HCl and 80 cc. of alc., followed by etching with 10 g. of $MgCl_2$ and 1 g. of $CuCl_2$ in 40 cc. of concd. HCl and 100 cc. of alc. H. STOERTZ

Supplementary discussion of the drop experiments of Evans. E. MAAS AND E. LIEBREICH. *Korrosion Metallschutz* **6**, 172–3(1930).—This is a reiteration of the belief in the convection currents explanation of the phenomena observed by Evans (cf. *C. A.* **24**, 3744, 5705). B. E. ROETHELI

The hardness testing of electrodeposits and other thin metallic coatings. HUGH O'NEILL. *Trans. Faraday Soc.* **27**, 41–51(1931).—The paper covers results obtained by indentation and by scratch tests, the same instrument being used as a *micro-Brinell tester* and as a scratch hardness tester. The factors involved in the hardness testing of thin metallic coatings are reviewed: (1) *surface finish*—the author finds that for his scratch test described he can, in many instances, secure satisfactory results by the use of 000 emery and slight hand polishing with a soft cloth moistened with a non-scratching metal polish; (2) *thickness of deposit*—a graph is given of the calculated minimum thicknesses of coating which may be accurately tested with various indenting tools loaded so as to produce indentations or scratches of various sizes; (3) *optical difficulties in making measurements* are apt to be great when a shallow indentation of relatively large diameter is being measured: a 0.5 mm. ball is suggested for indentation tests; (4) *internal stress in the coating* is mentioned as a theoretical possibility which may cause a slight opening out of a scratch or indentation; (5) *undue softness of the base metal* may affect the hardness result unless the coating is thick enough to carry all the effects of the deformation: the author has successfully tested an Fe film (0.004 in.) stripped and mounted on glass with Canada balsam as a means of overcoming this difficulty; (6) *local variations in electrodeposits* make it desirable to select the same locality for test on a number of plates. A machine designed by the author (*C. A.* **22**, 4433; **23**, 5456) utilizing a polished 1 mm. hemispherical diamond has been found suitable for the indentation and scratch testing of coatings down to less than 0.0005 in. in

The hardness testing of electrodeposits and other thin metallic coatings. HUGH O'NEILL. *Trans. Faraday Soc.* **27**, 41–51(1931).—The paper covers results obtained by indentation and by scratch tests, the same instrument being used as a *micro-Brinell tester* and as a scratch hardness tester. The factors involved in the hardness testing of thin metallic coatings are reviewed: (1) *surface finish*—the author finds that for his scratch test described he can, in many instances, secure satisfactory results by the use of 000 emery and slight hand polishing with a soft cloth moistened with a non-scratching metal polish; (2) *thickness of deposit*—a graph is given of the calculated minimum thicknesses of coating which may be accurately tested with various indenting tools loaded so as to produce indentations or scratches of various sizes; (3) *optical difficulties in making measurements* are apt to be great when a shallow indentation of relatively large diameter is being measured: a 0.5 mm. ball is suggested for indentation tests; (4) *internal stress in the coating* is mentioned as a theoretical possibility which may cause a slight opening out of a scratch or indentation; (5) *undue softness of the base metal* may affect the hardness result unless the coating is thick enough to carry all the effects of the deformation: the author has successfully tested an Fe film (0.004 in.) stripped and mounted on glass with Canada balsam as a means of overcoming this difficulty; (6) *local variations in electrodeposits* make it desirable to select the same locality for test on a number of plates. A machine designed by the author (*C. A.* **22**, 4433; **23**, 5456) utilizing a polished 1 mm. hemispherical diamond has been found suitable for the indentation and scratch testing of coatings down to less than 0.0005 in. in

thickness provided they are not much harder than about 400 Brinell. In both the micro-Brinell and scratch tests, loads up to 1 kg. were used. In the indentation tests the results are expressed as "ball numbers" in kg. per sq. mm., obtained by dividing the load by the projected area of the indentation (πr^2) instead of the spherical area (as required for the Brinell no.). The use of this "ball no." is recommended as being a more scientific value than the Brinell no. and being considerably easier to calculate than the Brinell no. while not differing greatly from it. A similar "cone no." is used in recording the results of micro-indentation tests using a 120° diamond cone. The scratch hardness no. is given by $P_s = (8L/\pi w^2)$ kg. per sq. mm. (L = total load on diamond, w = width of scratch made by hemispherical diamond). The scratch hardness no., under the conditions used, does not vary greatly with the testing load. An empirical conversion curve for obtaining *approximate* Brinell nos. from scratch hardness nos. is given. Tables showing the results of applying both the above tests to various metals, and the scratch test to Cd deposits of various thicknesses, to electrodeposits of various metals 0.02 mm. thick, and to Ni deposits (on steel) from baths of different compns., are given. It is suggested that a 0.5 mm. hemispherical diamond indented on a machine of the above general type would be of still greater utility, as harder deposits could then be tested. EDWARD B. SANIGAR

New method of making ball hardness tests of metals, and a plotting table for the simplification of Meyer (hardness) analysis. HUGH O'NEILL. *Iron and Steel Inst.* (London), *Carnegie Scholarship Mem.* **19**, 19–38(1930).—A crit. discussion of existing hardness-testing machines is followed by a description of a new diamond hardness test which uses an "unrecovered" indentation, dispenses with a measuring microscope, gives comparable hardness nos., has a const. rate of application of load and can be used for standard Brinell testing. The instrument is suitable for Meyer's hardness analysis. For hard materials a 1-mm. indenter is employed, while for soft metals and alloys a 10-mm. indenter is recommended. H. S. v. K.

Testing chromium plate for resistance to abrasion. HARRY C. WOLFE. *Metals and Alloys* **2**, 60–1(1931). A. J. MONACK

Materials of construction in aircraft engines. R. R. MOORE. *Proc. Am. Soc. Testing Materials* **1930** (preprint) No. 33, 46–56.—A discussion of the various *steels, bronzes, brasses and light alloys* most commonly used in aircraft engine construction. Phys. properties and chem. analyses of the alloys are tabulated and the applications of each alloy and the reasons for its specific uses explained in detail. W. H. BOYNTON

Ferrous metals used in airplane construction. J. B. JOHNSON. *Proc. Am. Soc. Testing Materials* **1930** (preprint) No. 33, 3–9.—Cast Fe and cast steel have but a limited application in aircraft construction. Standards on the chem. compns. as adopted by the Society of Automotive Engineers, in some cases with slight modifications, are applied in the airplane industry in the cases of rods, bars and billets. Rolled sheets and strips, tubes and wire are used in the industry. W. H. BOYNTON

Some notes on teeming speeds of ingots. A. JACKSON. *Iron Steel Ind. and British Foundryman* **4**, 167–70(1931).—A summary of the effects of teeming rates on 6-ton ingots. Rapid teeming rates tend to cause cracking. C. H. LORIG

Multi-component systems involving iron. III. The system: iron-phosphorus-silicon. W. HUMMITZSCH AND F. SAUERWALD. *Z. anorg. allgem. Chem.* **194**, 113–38 (1930); cf. *C. A.* **24**, 1049.—The system contg. an excess of Fe was examd. chemically, thermally and metallographically. Fe_2P–FeSi is quasi-binary. Fe–Fe_2Si–FeSi is an independent 3-component system. Fe_3P–FeSi is not quasi-binary. A ternary eutectic at 1018° consisted of 6.35% Si, 7.45% P, 86.20% Fe. At 1110° there is an equil. of the form: Liquidus k + Fe_2P = Fe_3P + FeSi. The liquidus is 13.55% Si, 6.00% P, 80.45% Fe. Eleven diagrams are given and discussed, also a no. of photomicrographs. B. A. SOULE

The expansion of iron. W. SCHRECK. *Giesserei-Ztg.* **27**, 1–3(1930).—Motor cylinders are cooled by water or air, but the pistons come in direct contact with hot gases and expand. On subsequent cooling the Fe does not contract to its original vol.; thereby it suffers a loss of strength. The modern light construction demands stringent specifications. High Si causes pptn. of the C as graphite, with accompanying expansion. Mn, and especially Cr, hinder the pptn. In order to regulate the compn. accurately, the Fe should be melted in an elec. furnace. CURTIS L. WILSON

The coefficient of expansion of cast iron. F. ROLL. *Giesserei-Ztg.* **27**, 4–7(1930).—A review of the effects of temp. and alloying elements upon the coeff. of thermal expansion of cast Fe. CURTIS L. WILSON

Shrinkage in cast iron in relation to the production of some special castings. R. T. ROLFE AND J. LAING. *Iron Steel Ind. Brit. Foundryman* **3**, 263–7, 284(1930). E. J. C.

Factors influencing the hardness of cast iron. AL. L. NORBURY. *Metallbörse* **20**, 1939–40(1930).—The influence of various factors upon the pptn. of fine graphite particles in the molten Fe is discussed. The addn. of graphitizing substances probably causes the pptn. of a large no. of finely divided graphite particles which are dissolved easier and quicker than the big flakes. Gray castings made with the addn. of such graphitizing substances show better strength values. Fe-Si, Ca-Si or Ni addns. have this effect. Mn and S by themselves favor the tendency toward hardening. Since they are always present at the same time, however, they neutralize each other through the formation of MnS. In order to neutralize the effect of S, an excess of 0.3% Mn over the quantity theoretically required for the formation of MnS is necessary. P seems to diminish the tendency toward hardening of thin pieces cast in sand molds. The tendency toward hardening is diminished by Al, Ni, Cu and Co, while it is increased by V, Cr, Se, Mo, Sn, Sb and W. LEOPOLD PESSEL

Effects on cast iron of prolonged heating at 800–1100°F. R. S. MACPHERRAN AND REXFORD H. KRUEGER. *Trans. & Bull. Am. Foundrymen's Assoc.* **2**, 826–64(1931).—See *C. A.* **25**, 60. C. H. LORIG

Chromium in cast-iron mixtures. T. F. JENNINGS. *Trans. & Bull. Am. Foundrymen's Assoc.* **2**, 801–9(1931).—See *C. A.* **24**, 4743. C. H. LORIG

Effect of nickel and silicon on the properties of whiteheart malleable cast iron (with special reference to thin-walled malleable). I. S. J. E. DANGERFIELD, F. JOHNSON AND E. R. TAYLOR. *Iron and Steel Inst.* (London), *Carnegie Scholarship Mem.* **19**, 1–18(1930).—The effect of Ni on cupola-melted white cast iron used for thin-walled malleable castings was investigated. The test bars, $^3/_{16}$ in. thick, contained C 3.4, Si 0.65, S 0.2, P 0.05 and Mn 0.08%. The content of Ni varied from 0 to 3.66%. Ni improves the fluidity of the molten alloy. The tensile strength increases to a max. of 22.7 tons/sq. in. at 2.5% Ni and falls to 6.4 tons/sq. in. at 3.66% Ni. Bend tests give the best results at 0.7% Ni. The machinability is not impaired by the presence of Ni. In the annealed bars Ni causes a diminution in the size of the C nodules, and up to 2.8% a retardation in the rate of C migration, thus retaining more combined C in the form of an intercryst. network. This is attributed to a widening of the temp. interval of the Ar_1 range due to the Ni content. Above 2.5% Ni there is a rapid decrease in the percentage of combined and total C left in the annealed bars. With 3.6% Ni only 0.085% C is left and a severely burned material results. H. S. v. K.

The influence of phosphorus, sulfur, nickel and chromium on the growth of cast iron. O. BAUER AND K. SIPP. *Die Giesserei* **17**, 989–95(1930).—Investigations to det. the influence of P, S, Ni and Cr on the primary growth (by annealing tests), and the carbide decompn. or the graphite sepn. from the solid soln. (metallographically) of cast Fe are described. The growth is promoted by Si, P and Ni and is retarded by Cr, Mn and S (in large amts.), while S in small quantities and C have no influence. Below the pearlite point P promotes the carbide decompn., and at high temps. the C sepn. from the solid soln. Cr and Mn tend to retard both these, while S in small quantities does not influence the carbide decompn. In large amts. S tends to act strongly against both this decompn. and the C sepn. Micrographs (18) are given. J. BALOZIAN

Effects of alloys in cast iron. R. C. GOOD. *Trans. & Bull. Am. Foundrymen's Assoc.* **1**, No. 8, 15–28(1930).—A review is given of the effects of alloying constituents. The influence of C, Si, P, S, Mu, Cr, Ni, Co, V, Ti, Al, Cu, Mo, W and Zr is discussed. LEOPOLD PESSEL

Some notes on cast-iron plating tools. ROGER POWELL. *Iron Steel Ind. and British Foundryman* **4**, 161–2(1931).—From service records the essential of a good plating tool appears to be a good chill $1^1/_2$ to 3 in. deep. C. H. LORIG

Microstructure of pig and cast iron. H. PINAL. *Giesserei-Ztg.* **27**, 436–47(1930).—A series of 133 photomicrographs showing the various structures of P, graphite, combined C and slag in pig Fe and cast Fe. CURTIS L. WILSON

The properties of pig irons from various sources. A. WAGNER. *Giesserei-Ztg.* **27**, 403–12(1930).—Chem. analysis is not an exclusive criterion of the value of pig Fe, as many varieties of the same compn. exhibit different properties. The behavior of 17 types of pig Fe, such as English hematite, foundry and Swedish charcoal Fe was investigated by melting and remelting several times in crucibles, under as const. melting conditions as possible, and examg. specimens for tensile and bending strength, hardness and microstructure. The first melting resulted in materials of low tensile strength, 8.5–12 kg., and low bending strength, 18–19 kg. Repeated remelting improved the phys. properties: after the 4th melting, the tensile strength increased 100% without any appreciable change in compn. Numerous photomicrographs are reproduced. CURTIS L. WILSON

The causes of blisters and pinholes in wet-process cast-iron enamel. WALTER KERSTAN. *Die Giesserei* **17**, 965–72(1930).—Plant and lab. expts. were carried out to det. the causes of blisters and pinholes in cast-Fe enamels produced by the wet process. These defects are shown to be due to the simultaneous action of various causes, principal among which are: (1) incorrect compn. of the frit, (2) phys. defects in the cast Fe, (3) insufficient cleaning of the casting surface, and (4) various changes in the Fe structure during the baking of the enamel. Cast Fe in which the graphite is finely divided is the most stable during baking and shows the least change in structure during the enameling process. J. BALOZIAN

Etching figures appearing in iron and steel. V.-N. SVECHNIKOV. *Rev. métal.* **27**, 512(1930). C. H. LORIG

The study of special steels—constitutional diagram of the 18 per cent Cr alloys with variable composition of nickel and carbon. V. N. KRIVOBOK. *Mining Met. Investigations U. S. Bur. Mines, Carnegie Inst. Tech., Mining Met. Advisory Boards, 4th Open Meeting of the Met. Board*, Oct. 17, 1930, 4 pp.—An outline is given of problems begun or to be carried out on 18% Cr-Fe alloys contg. variable percentages of Ni and C. C. H. LORIG

Mechanical properties of copper steels with special reference to the effect of heat treatment. F. NEHL. *Stahl u. Eisen* **50**, 678–86(1930).—The addn. of more than 0.6% Cu to mild steel increases the yield point appreciably but tends to make the metal brittle, a tendency which is overcome by the addn. of 0.4% Cr. This alloy has a much higher tensile strength and yield point at high temps. than Si steel and is more resistant to corrosion. Quenching from above 800° and tempering at 450–550° increases the tensile strength of steels with more than 0.6% Cu without seriously reducing the ductility and resistance to shock. Tables and graphs are given showing the effect of various heat treatments on the mech. properties of several Cu steels after varying mech treatment. B. C. A.

Vibratory strength of nitrided steel. O. HENGSTENBERG AND R. MAILÄNDER. *Krupp. Monatsh.* **11**, 252–4(1930).—A considerably higher vibratory strength is shown by the nitrided specimens as compared with the same steels not nitrided. This depends on the relative depth of nitrided layer and core as well as upon the type of steel. The first breakdown always occurs at a point on the border of the nitrided layer, although this layer shows very little plastic deformation. Small surface defects are without effect upon the vibratory strength of nitrided samples. H. STOERTZ

Practical importance of the influence of different cooling conditions on the structure of steel ingots. F. LEITNER. *Stahl. u. Eisen* **50**, 1081–6(1930).—The effect of varying wall thicknesses of the mold on the structure of plain C and Ni-Cr steels has been examd The results show that a more fine-grained and homogeneous macrostructure is obtained by retarded cooling, and hence thin-walled molds are to be preferred. Even better structures are produced by retarding the radiation of heat from the mold by covering it with a heat-insulating material or by using a double-walled mold with an annular air space between the walls. B. C. A.

Drawing of rapidly quenched steel. ANDRÉ MICHEL AND PIERRE BENAZET. *Compt. rend.* **192**, 163–6(1931).—A study is made of the influence of drawing time and temp. on the transformation of austenite to martensite in a high-speed steel contg C 0.72, Si 0.33, Mn 0.26, Cr 5.20, W 18.33, V 1.02 and Co 11.09%. Co in steel increases the effect of secondary tempering. C. H. LORIG

Drawing of special rapidly quenched steels. ANDRÉ MICHEL AND PIERRE BENAZET. *Rev. métal.* **27**, 501–8(1930).—Dilation characteristics of 16 alloy steels were detd to study the γ-α transformation. C. H. LORIG

The annealing of steel. P. CHEVENARD. *Metallbörse* **20**, 1828(1930).—The hardening of steel was investigated by means of photomicrographic, magnetic and dilatometric methods. Dilatometric curves were detd. for the thermic cycles of growth with gradually increasing temps. and also for the phenomena of isothermic growth under exact detn. of the change of length as a function of the time. A special dilatometer with movable photographic plates was used. Constant temp. was insured by special construction. The investigations were made on austenite, the only constituent that can be obtained in a pure state. It was investigated in the state of complete superhardening. A mixt. of austenite-martensite was investigated in a partially superhardened condition and the greatest hardness obtainable was detd. in a quenched steel contg. the max. amt. of martensite. The phenomena can be explained by the equil. diagram but they are complicated by the simultaneous occurrence of the various reactions. C. could eliminate the influence of the simultaneous reactions which had caused the variations of results before. Austenite can lead to the formation of cementite,

a reaction which causes contraction, or a mixt. of α-Fe and cementite may be formed under expansion. The formation of martensite, which follows that of austenite, is connected with a contraction that grows with the temp. In quenched steels there is always a simultaneousness of these 2 phenomena, causing in certain sections of the expansion curve either an arrest in the contraction, a rise or a slowing down. A direct transition of austenite into martensite during heating could never be observed. This secondary reaction in hardening always occurs in the second period of cooling. This simultaneousness of the phenomena in martensite and austenite can also be observed by means of the elec. cond. LEOPOLD PESSEL

Solution of scale in pickling steel. E. L. CHAPPELL AND PAUL C. ELY. *Ind. Eng. Chem.* **22**, 1200-1(1930).—In pickling welded pipe 95% or more of the scale goes into soln., the undissolved part consisting mainly of Fe silicates. The rate of scale soln. is about equal to the rate of metal soln. in the absence of an inhibitor. The rate of scale soln., is about the same with or without an inhibitor. Scale on pipe is more quickly and completely dissolved than scale in acid without metal. L. P.

Pickling solution for stainless and nickel steel. W. E. WARNER. *Machinery* **36**, 626–7(1930); *Metals and Alloys* **1**, 737.—Proportions given are: 9 parts water, 1 part H_2SO_4, 1 part HCl and 1 part HNO_3. G. G.

Economic pickling of thin metallic sheets. E. DWORZAK. *Przemysl Chem.* **14**, 361–73(1930).—The rate of soln. of thin sheets of Fe and Zn in 1–25% H_2SO_4 at 30–50° was studied with and without the addn. of certain inhibitors. This rate for Fe was followed by measuring the vol. of evolved H. In H_2SO_4 alone the rate of soln. of Fe increases rapidly with temp. At 30° this rate is markedly greater in 35% than in 5% acid, but is nearly the same for all concns. at 50°, when 1 cc. H is evolved per 1 cm.^{2} of the surface per 20 min. The addn. of 1–15% naphthalenesulfonic acid (I) or "Passiv" to 15% H_2SO_4 reduces the rate of evolution of H markedly and causes the rates for various concns. of acid to remain different even at the higher temps. The effect of the addn. of 0.1–2% "Vogel's compd.," or "compd. K" (author's prepn.) is to repress the rate of H evolution still further, although the former ceases to function at 50° after 30–40 min. while the latter continues to maintain its inhibiting property. The advantage of speeding up the pickling of Fe by increasing the temp. or concn. of the acid is only apparent, because the increased rate of H evolution is not only a sign of an increased rate of consumption of Fe and acid but is also harmful to the metal. The pickling process is speeded up appreciably by the addn. of inhibitors. Their concn. seems to have little effect on the rate of H evolution at the higher temps. H_2SO_4 alone removes the oxide scale on Fe sheet in small chunks. In the presence of I these chunks are larger. In the presence of "Vogel's compd." or "compd. K" there is no H_2 observed at all until after several min. the whole surface of the oxides suddenly peels off. A study of the rate of soln. of Fe oxide scale in H_2SO_4 in the presence of the above inhibitors leads D. to conclude that evidently the negative catalytic effect of the inhibitors pertains to the soln. of metals in acids, and of those reactions which are accompanied by evolution of H, and not to the metal oxides. Tests show that the inhibitors increase the rate of soln. of the scale, although in com. practice only a negligible amt. of scale is dissolved. In pickling, the scale is forced away from the metal by H which is produced by the action of the acid on the metal. A study of the efficiency of the utilization of acid showed that 40 kg. 60° Bé. H_2SO_4 is needed for pickling 1 T iron sheet, 1 sq. m. surface and 1 mm. thick in 15% acid, whereupon 2.3% metallic Fe is dissolved. The addn. of 3% "Passiv" reduces this to 1.06%. The corresponding figure for "Vogel's compd." is 0.78%, and for "compd. K" 0.53%. A. C. ZACHLIN

Pickling of pipe using commercial inhibitors. E. L. CHAPPELL AND PAUL C. ELY. *Ind. Eng. Chem.* **22**, 1201-3(1930).—The use, lab. control and practical evaluation of inhibitors are discussed. LEOPOLD PESSEL

General principles underlying the use of alloy steel. R. WHITFIELD. *Iron and Steel Ind. and British Foundryman* **3**, 347-50(1930).—A review. LEOPOLD PESSEL

The constitution of alloys. The application of physical methods. ALFRED SCHULZE. *Giesserei Ztg.* **27**, 86-97(1930).—Of all the properties used to study the constitution of alloys, the elec. cond. is the easiest to comprehend and the most sensitive toward slight changes in constitution. The change in elec. cond. for binary systems which show complete insoly. in the solid state, when plotted against the vol. concn., is not quite linear; it is not the arithmetic mean, but the geometric mean, of the elec. conds. (and elec. resistivities). For complete miscibility in the solid state, the curve of elec. cond. decreases rapidly and has in the middle a flat min. The resistance resulting from solid solns. is independent of the temp. When a system shows partial soly. in the solid state, the elec. cond. curve decreases rapidly within the limits of soly. and then changes almost

along a straight line. When a chem. compd. is formed, a distinct break in the elec. cond. curve is noted at the concn. of the compd. The relation between concn., temp., and elec. cond. is shown on space models. CURTIS L. WILSON

The thermal properties of various alloy groups. ALFRED SCHULZE. *Giesserei-Ztg.* 27, 177–84(1930); cf. preceding abstr.—Next to the elec. cond., the thermal expansion of alloys throws the most light upon their constitution. The tube method of dilatometric analysis is both sensitive and exact. For systems completely insol. in the solid state, the coeff. of thermal expansion is a linear function of the vol. concn. For complete soly. in the solid state, the curve of the coeff. of expansion is convex toward the concn. axis. This deviation from a straight line is explained as due to the fact that an atom of the one component displacing an atom of the other disturbs the space lattice so that the av. distance between the atoms is not proportional to the concn. For partial soly. systems, the coeff. curve is similar to that of solid solns. within the soly. limits, outside of which it is a straight line. The thermal cond. is similar to the elec. cond. with respect to its relation to the constitution of alloys. Magnetic and x-ray analyses are also discussed. CURTIS L. WILSON

Structural and engineering light alloys for aircraft. R. L. TEMPLIN, F. V. HARTMAN AND E. C. HARTMANN. *Proc. Am. Soc. Testing Materials* 1930 (preprint) No. 33, 10–6.—The wrought and cast alloys of Al and Mg best suited to aircraft work and their respective advantages are discussed. The designation of the various alloys available is indicated and the forms in which they are produced commercially given. Data on nominal compn., heat treatment and mech. properties are tabulated. W. H. B.

Alloys for drilling purposes. N. PRAVDYUK AND V. NEGREEV. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* 1930, No. 12, 99–112; cf. *C. A.* 24, 2406.—Analyses and descriptions are given of various alloys which were tested for hardness and resistance to wear. Expts. indicate that alloys contg. W can be successfully applied to drilling. V. K.

Alloyed castings. E. KOTHNY. *Giesserei-Ztg.* 27, 291–300, 323–7(1930).—A review of the effects of Ni, Cr, Ni-Cr, Ti, Al, B, Ce, Co, Cu, W, Mo, V and Zr upon the constitution and the phys. and chem properties of gray, chilled and malleable Fe castings. A bibliography is appended. CURTIS L. WILSON

Processes involved in age-hardening. G. TAMMANN. *Z. Metallkunde* 22, 365–8 (1930).—The theory of age-hardening is discussed generally. It is concluded that the increase in hardness and strength observed in age-hardening alloys cannot be explained by the blocking of slip-planes by ppt. alone, but that the chief effect must be a pre-pptn. assocn. of the pptg. mols. in the supersatd. solid soln The importance of the form of the ppt. (Widmanstatten figure) and of the process of coagulation is discussed. R. F. MEHL.

Age-hardening of alloys. W. GUERTLER. *Z. Metallkunde* 22, 78–84(1930).—A review, chiefly of the theoretical aspects. ROBERT F. MEHL

The age-hardening of Constructal. G. WASSERMANN. *Z. Metallkunde* 22, 160–2 (1930).—The changes in lattice parameter during aging of the alloy Constructal (Al with 5.88% Zn, 1.40% Mg, 1.35% Mn, 0.28% Fe, 0.20% Si) was studied. It was found that the lattice const., a_0 (the side of the unit face-centered cube of the Al solid soln.) decreased by 0.0015 A. U. upon room temp. aging for one day or artificial aging at 80° for $^1/_2$ hr. Annealed wire showed the presence on the x-ray spectrogram of $MgZn_2$. The strongest line of $MgZn_2$ may be found on the spectrogram after only $^1/_2$ hour's aging at 80°. It was not possible to prove the presence of $MgZn_2$ ppt. in alloys aged only at room temp. ROBERT F. MEHL

Brinell hardness, elastic limit, and ultimate tensile strength of age-hardening aluminum alloys. P. MELCHIOR. *Z. Metallkunde* 22, 175–6(1930).—The equations suggested by Bohner (*C. A.* 24, 1067) to express empirical relationship between these quantities are discussed and simpler and more accurate equations proposed. ROBERT F. MEHL

The hardening problem in copper-silver, beryllium-copper and zinc-copper alloys. M. HAAS AND D. UNO. *Z. Metallkunde* 22, 154–8(1930).—*Cu-Ag.*—Earlier work on the solid soly. of Cu in Ag is summarized. A new solid soly. curve is established by measurements of thermal expansion (dilatometric) and of elec. resistance, and by microscopic studies on quenched and annealed alloys. The maximums upon the dilatometric curve and the elec. resistance curve correspond to the max. upon the hardness curve *Be-Cu.*—Dilatometric curves on the Cu-rich solid soln. are given. Hardness measurements are in good agreement with the dilatometric. *Zn-Cu.*—A few dilatometric curves are given for alloys cooled from the β field. Throughout this work an attempt is made to trace the course of pptn. by means of changes in volume and to correlate these changes

and therefore the various stages in the pptn. process with the changes in hardness observed. ROBERT F. MEHL

The alloys of aluminum. L. POTIN. *Rev. gén. sci.* **41**, 474–7(1930).—A review. LEOPOLD PESSEL

Cast aluminum bronzes. III. Shrinkage phenomena. W. CLAUS AND F. GOEDERITZ. *Die Giesserei* **17**, 1017–23(1930); cf. *C. A.* **24**, 4497.—In studying the macrostructure of cast Al bronzes, castings of 4.5, 7 and 10% Al, and a Si-Al bronze are made in dry and moist sand and in chill molds, pouring at 1250°. Shrinkage pipe is present in the core of the 7 and 10% Al bronzes when cast in either the dry or the moist molds. The 4.5% Al bronze shows small defects in the bottom of the casting, but no shrinkage pipe in the head. This bronze when cast in a chill mold gives a dense casting. Shrinkage pipes are shown by the 4.5, 7 and 10% bronzes when cast in chill molds. The Si-Al bronze shows slag defects in the foot when cast in the sand molds, and a central porosity when cast in the chill mold. Lower pouring temps. (1050°) do not affect the shrinkage pipe in the 10% Al bronze when cast in the dry sand mold. J. BALOZIAN

Ternary alloys of aluminum, silicon and copper. G. G. URAZOV, S. A. POGODIN AND G. M. ZAMORUEV. *Mineralnoe Suir'e i Tzvetnuie Met.* **4**, 160–95(1929).—A study, by thermal analysis, of the Al triangle up to 24% Si and 40% Cu is given. The alloys in this range consist of mech. mixts. of Si, $CuAl_2$ and a solid soln. of Si and Cu in Al. The soly. of Cu is increased by Si in the interval 450–350°. The hardness of the ternary solid solns. was detd. Aging of the alloys at the ordinary temp. diminishes with increasing content of Si. The technical application of the results is considered. B. C. A.

Bismuth alloys. J. G. THOMPSON. *Metals and Alloys* **2**, 92–4(1931).—See *C. A.* **25**, 670. A. J. MONACK

Crystal structure of the alloys of iron and manganese. JAMES B. FRIAUF AND MAXWELL GENSAMER. *Mining Met. Investigations U. S. Bur. Mines, Carnegie Inst. Tech., Mining Met. Advisory Boards, 4th Open Meeting of the Met. Board*, Oct. 17, 1930, 6 pp.—X-ray analyses show α-Fe is present in Fe-Mn alloys up to at least 16% Mn. γ-Fe makes its appearance at room temp. in the forged alloys with 13% Mn. Another phase, the hexagonal close-packed arrangement, was found in forged alloys contg. 10 to 26% Mn. C. H. LORIG

Constitutional diagram of iron-manganese alloys. V. N. KRIVOBOK. *Mining Met. Investigations U. S. Bur. Mines, Carnegie Inst. Tech., Mining Met. Advisory Boards, 4th Open Meeting of the Met. Board*, Oct. 17, 1930, 3 pp.—A tentative constitutional diagram was constructed from data supplied by thermal analysis, metallographic studies and x-ray patterns. It is believed there are at least 6 different phases: α-Fe, γ-Fe, ε-Fe, α-Mn, β-Mn and γ-Mn. C. H. LORIG

Heat treatment and metallography of the alloys of iron and manganese. V. N. KRIVOBOK AND CYRIL WELLS. *Mining Met. Investigations U. S. Bur. Mines, Carnegie Inst. Tech., Mining Met. Advisory Boards, 4th Open Meeting of the Met. Board*, Oct. 17, 1930, 4 pp.—Dividing the Fe-Mn alloys into 6 groups, K. and W. discuss the microstructure of each group individually but briefly. C. H. LORIG

Thermal analysis of iron-manganese alloys. F. M. WALTERS, JR., AND CYRIL WELLS. *Mining Met. Investigations U. S. Bur. Mines, Carnegie Inst. Tech., Mining Met. Advisory Boards, 4th Open Meeting of the Met. Board*, Oct. 17, 1930, 6 pp.—Thermal analyses were made in a gradient furnace on Fe-Mn alloys contg. 1.7, 4.4, 7.2, 10.2, 13.1 and 16% Mn with an av. of 0.02% C. A sudden change in thermal disturbance was observed in alloys contg. 13 and 16% Mn. C. H. LORIG

Ternary alloys of lead. S. J. NIGHTINGALE. *Brit. Non-Ferrous Metals Research Assoc. Develop. Rept.* **D3**, 12 pp.(1929).—The properties of Pb alloys contg. (*a*) 0.25% Cd and 0.5% Sb and (*b*) 0.25% Cd and 1.5% Sn are compared with those of pure Pb as regards their utility for the manuf. of pipe. The tensile strength of the alloys is 1.62 tons/sq. in. compared with 0.9 ton/sq. in. for pure Pb, the ductility 52–55% against 80% and the fatigue limit 0.74–0.57 ton/sq. in. against 0.18. The alloys are on the whole more resistant to corrosion than is Pb and withstand a considerably higher bursting pressure, so that a lighter pipe can be used for the same service than is the case with Pb. The working and soldering properties of the alloys are equally as good as those of lead and, taking into account their superior properties, are relatively less costly than Pb; they do not undergo intercrystalline corrosion or fatigue. B. C. A.

Silicon-zinc-copper alloy. E. VADERS. *Metal. Ind.* (N. Y.) **29**, 108–10(1931).—See *C. A.* **25**, 63. G. G.

Useful titanium alloys. W. KROLL. *Metallwirtschaft* **9**, 1043–5(1930).—Fe-Ti

alloys can be rolled and may be used as alloy steels. With high Ti content they are susceptible to aging. Their grain structure is very coarse. Ni reduces grain size and increases the age-hardening effects. The alloys are compared to those of Fe-Be. C. H. LORIG

Directional properties in cold-rolled and annealed copper. ARTHUR PHILLIPS AND E. S. BUNN. *Am. Inst. Mining and Met. Eng. Tech. Pub.* No. **413**, 18 pp.(1931).—The paper deals with the directional differences in the tensile properties of 2 kinds of sheet Cu: tough pitch Cu contg. 0.0295% Ag and electrolytic Cu deoxidized with P (residual P 0.0089%). The first series of tests was on the cold-rolled Cu, reduced 10–90% Tensile tests were made on strip cut (1) in the direction of rolling, (2) at 90 degrees and (3) at 45 degrees to the direction of rolling. In the second series the 3 kinds of strips cut from the rolled sheets were annealed over a temp. range extending from 300° to 800°. The results seem to indicate that rather pronounced directional differences, particularly in elongation values, are produced by the combined effects of heavy reductions and high temps. of anneal. C. L. MANTELL

Duplexing. K. R. BINKS. *Iron and Steel Ind. and Brit. Foundryman* **4**, 194, 198 (1931).—Processes are described. C. H. LORIG

Parkerizing. E. LIEBREICH. *Z. angew. Chem.* **43**, 769–71(1930).—The reactions underlying this process and the qualities of the coatings obtained are discussed. LEOPOLD PESSEL

An inquiry into lead poisoning during coating with lead on metal. E. AGASSE-LAFONT. *Med. Travail* **1**, 277–9(1930); *Bull. Hyg.* **5**, 923–4.—Metals are coated by plunging the red-hot metal into the metal powder or by sprinkling the powder on the hot metal and returning the metal to a hot furnace where it melts and spreads. The powder may contain 66% of Pb_3O_4. The air is so laden with the powder that 6.6 g. (contg about 4 g. of Pb) were collected on each sq. m. of surface per hr. Basophile granulated red cells were found in the blood of 90% and 80% showed the blue line. They suffered from colic. Symptoms of plumbism were present after a few days' employment. GEORGE R. GREENBANK

Risks in new methods of spraying. W. ROSENTHAL, D. ROSENTHAL AND ERIKA. *Deut. Med. Wochschr.* **56**, 1444–67, 1487–9(1930); *Bull. Hyg.* **5**, 926.—The authors describe "metallization" in which molten metal is blown onto a surface by compressed air. Cellulose spraying is described in which turpentine, C_6H_6 and its much less dangerous homologs PhMe and $C_6H_4Me_2$ are used. Particular stress is laid on the dangers of MeOH as likely to produce optic nerve neuritis. Among the poisonous coloring matters discussed Pb and Si are the most dangerous. The value of periodic medical examn. is stressed, and the symptoms which if present should result in suspension of the worker are indicated. Symptoms of poisoning by C_6H_6, Pb and Si are described GEORGE R GREENBANK

Protecting iron from rust. DIECKMANN. *Farbe u. Lack* **1931**, 87–8.—An address G. G. SWARD

Corrosion-resisting cast iron. W. ACKERMANN. *Giesserei-Ztg.* **27**, 263–6(1930).—As corrosion is regarded as an electrochem. process the homogeneous structure of solid solns. is most favorable to resistance. Graphite accelerates corrosion. Si causes the pptn. of graphite, but a cast Fe with 0.84% Si corrodes more rapidly than one with 2.25% Si. The resistance of the higher Si casting is attributed not to the graphite but to the Si which is in solid soln. P up to 0.5% increases resistance, but more than 0.07% S is detrimental. From 14 to 22% Si creates an acid-resisting material, which is not recommended for alk. solns. Ni, Cu and Cr reduce the rate of corrosion under certain conditions. The addn. of Monel metal to cast Fe produces an austenitic structure and a resistance to corrosion almost equal to that of bronze. C. L. W.

Corrosion-prevention methods as applied in aircraft construction. H. S. RAWDON. *Proc. Am. Soc. Testing Materials* **1930** (preprint) No. 33, 30–6.—A résumé of present com. practice on corrosion-prevention. Steel structural parts are plated either with Cd or Zn, followed by an iron-oxide primer and a lacquer or enamel. The inside of closed tubular members is coated with the primer. In Navy practice duralumin is treated by the anodic-oxidation process prior to the application of a priming coat, followed by the finishing coat. Army practice is to have a careful preliminary chem. surface cleaning followed by a priming coat and finishing coats. Special precautions against "crevice" corrosion involve the use of rubberized balloon tape, bitumastic paint or similar product between metal parts and wood, leather, etc., and the use of "dope-proof" paint or Al foil on top of the protective coating already applied. Duralumin and steel parts before assembly by riveting or bolting are coated with primer or Navy gray enamel on the contact surfaces. Bare Al surfaces are cleaned by the use of a

mild etching soln., such as a dil. soln. of H_3PO_4. Another soln. is a caustic "dip" followed by neutralization with weak acid. Mild abrasives may be used, even sand blasting for heavier parts, each followed by chem. cleaning. W. H. BOYNTON

Corrosion exfoliations on aluminum sheet. LEOPOLD PESSEL. *Metal Ind.* (N. Y.) 29, 72–3(1931).—The phenomenon of corrosion exfoliations, which is quite different from the commonly observed forms of corrosion of Al, can be observed on Al sheet exposed to continuous salt spray. This phenomenon is explained on the basis of the O concn. cell theory, under the assumption that min. crevices, formed as a consequence of the rolling process, are made the anodic areas because of the exclusion of O. The formation of a large vol. of Al hydroxide takes place in these sections, causing the blister-like raising of the adjoining metal. It was shown by expt. that Al sheet, sand-blasted and sprayed with molten Al by the metal spraying process, will not show this type of corrosion. LEOPOLD PESSEL

The corrosion of copper and high-copper alloys by salt solutions with special consideration of conditions existing in the potash industry. A. RAUCH AND H. KOLB. *Korrosion Metallschutz* 6, 151–6, 174–8, 193–200(1930); cf. *C. A.* 24, 4750.—Corrosion-time curves obtained by the corrosion of Cu in 1.35 *N* KCl and 1.35 *N* $MgCl_2$ solns., while of a linear nature, show a kink after approx. 1 hr., coinciding with the time when a deposit of basic Cu chloride could be observed. Solns. of Na_2SO_4 and $MgSO_4$ were much less active toward Cu than the chlorides. The curves obtained show considerable "spreads," making it difficult to draw a definite conclusion. A comparison between electrolytic Cu and 4% Al bronze showed that the linear relation between time and corrosion is found with Cu alloys, also. While the corrosion was greater with chlorides than with sulfates, there was also found a distinct relation between the nature of the anion and corrosion. In different salts having the same anion, the corrosion was the same at equal concns. of this anion. With increasing velocity of the liquids a slow increase of corrosion could be ascertained. The curve apparently approached a max. An app. is described in which the corrosion of Cu was accomplished in the absence of O. As was to be expected, the corrosion in solns. free of O was found to be only a fraction of that observed in the presence of air. In the absence of O the corrosion is practically not influenced by changes in concn., temp. and time of exposure. It is also equally intensive with chlorides and sulfates. In the absence of air, pure Cu and Cu alloys show the same behavior. Here too, no essential influence of concn., time and temp. could be found. Technical salt solns. were found to give practically the same result. The small difference in the corrosion values found in the presence and absence of air can be explained by the low O content of the solns. and by the tenacious retention of O in these concd. solns. For the *detn. of O in salt solns.* Winkler's Mn hydroxide method was modified for solns. contg. Mg salts by using NH_3 contg. NH_4I and NH_4Cl in place of NaOH. This method gave good results. The concn. of O in salt solns. was found to decrease with increasing concn. The influence of the temp. upon the O concn. was detd by modifying the app. The soly. of O decreases with increasing temp., the relation being expressed by a linear curve, apparently up to the b. p. of the solns. No quant. relation could be found between O soly. and corrosion. The corrosion reaches a max. at 20% KCl. From there on influences favoring and counteracting corrosion are apparently active at the same time. Leaching solns. attack Cu much less than KCl solns. of moderate concn.; this is explained by the lower soly. of O in the former. The temp. coeff. of corrosion in leaching solns. is also smaller. An experiment made to ascertain the attack by carried-over solid salts indicated the negligible degree of this factor. Solid $MgCl_2$, however, can, if in contact with Cu at increased temp., induce corrosion by splitting off HCl. The extent of corrosion of various Cu-bearing alloys was investigated. Al bronze was generally found superior to smelters Cu, electrolytic Cu, tin bronze and brass. While the latter showed greater resistance in one expt. with flowing KCl solns., the danger of severe local dezincification exists and suggests Al bronze as the more advisable material. Smelters Cu was found to be least resistant; electrolytic Cu came next, except in higher KCl concns., where Sn bronze showed greater attack. In an investigation of etched and copper-plated Cu sheets the influence of the surface condition upon corrosion was found to be negligible. Cold-worked Cu and Cu alloys were found to be more attacked than the soft annealed material. *Potential measurements* were made on electrolytic Cu, Al bronze and Sn bronze along with detns. of the corrodibility. No connection was found between the latter and the electro-chem. behavior. Electrolytic Cu, which showed the greatest corrosion, always had the noblest potential. In comparing the potentials of "soft" and "hard" electrolytic Cu with the corrodibility, it was found that the hardened metal, although of a lower potential, was less attacked. A soft and a hard Al bronze showed

the same amount of corrosion and yet a distinct difference in the potential. In comparing normal and cold-worked metal sheets, the latter always showed a more neg. potential and also greater corrosion. By direct measurement of electrolytic Cu and Al bronze electrodes, the latter were always found to be anodic. The conclusion is that the potentials cannot be considered a general indication of the corrosion resistance of the material. Electrolytic Cu became more anodic with increasing concn. of KCl. Expts. were made to determine whether Toedt's methods of measuring corrodibility by residual currents could be applied in the case of electrolytic Cu and Al bronze. The combination Pt-Al bronze gives a current 2–3 times as strong as the combination Pt-electrolytic Cu, which stands in contradiction to the repeatedly detd. greater corrosion resistance of Al bronze. In other expts. the quantity of residual current and the corrodibility were detd. at the same time. The latter was found to be 2–8 times as great as the values calcd. from the quantity of current. In other expts. the quantity of current was found to be the smaller the greater the loss of weight due to corrosion. No definite regularity can as yet be found in the relation between residual current and corrosion. Corrosion expts. were made with a larger exptl. installation. An app. recirculating 150 l. of leaching soln. is described. Al bronze was found to have the greatest resistance against corrosion, being about 7 times better than electrolytic Cu. In the expts. on a smaller scale this proportion had been found to be less pronounced. Sn bronze of 1.5% Sn showed a corrodibility similar to Cu. LEOPOLD PESSEL

Welding aluminum. FRED GROVE-PALMER. *Metal Ind.* (London) **33**, 509–10, 533–4, 546(1928). E. J. C.

Soldering and welding aluminum and its alloys. ERNST WEBER. *Giesserei-Ztg.* **27**, 72–6(1930).—Al and its alloys are difficult to solder because (1) the thin skin of thermally resistant and chemically inert oxide hinders a firm alloying of the metal and solder; (2) the high sp. heat and thermal cond. of Al cause in spots a "quenching" of the liquid solder and (3) the strong electropos. nature of the metal sets up reactions in the presence of liquids or moist air. Most modern Al solders consist principally of Sn with some Al and Zn. Many contain also Sb, Bi, Cd, Cu, Pb, Ni, Ag and other metals. Soldered joints are tested in steam, boiling salt soln. or boiling water for several days. The tensile strength is 5 kg./sq. mm., which is lower than that of Al. In order to meet chem. and mech. specifications, autogenous welding is recommended. Al is one of the most weldable of metals, if the following characteristics are kept in mind: (1) low resistance against oxidation, (2) high coeff. of expansion, (3) high thermal cond., (4) low m. p., (5) low tensile strength at high temps., (6) tendency to warp. Modern fluxes consist of alk. chlorides, fluorides, bisulfates, etc. A slightly reducing oxyacetylene flame gives good results. Welded joints should be guarded against too rapid cooling. CURTIS L. WILSON

Froth-flotation concentration of ores. PERCY C. WRIGHT (to The Minerals Separation North American Corp.). Can. 309,071, Mar. 3, 1931. Ore in the form of a non-acid pulp is subjected to a froth flotation operation in the presence of dixanthogen.

Mat (including a perforated sheet of rubber) for distributing air through liquids in ore flotation or other processes. WALTER H. CURRY and HENRY F. DIETZ (to Hewitt-Gutta Percha Rubber Corp.). U. S. 1,792,285–6, Feb. 10. Structural features.

Grading ores by weight for air blast hearths. REMBRANDT PEALE, WM. S. DAVIES and WM. S. WALLACE. Ger. 513,787, Aug. 18, 1923. Details of the app. are given.

Values from ores by leaching and electrodeposition. R. SANZ CARRERAS. Brit. 336,584, July 10, 1929. Ores contg. Cu, Ni and Co are leached with a dil. H_2SO_4 soln. contg. NaCl (suitably about 5%). Any insol. portion of the ore, which may contain arsenides and sulfocyanides, is oxidized in a furnace and again leached, and the solns. obtained may be further treated together or separately. The liquid, about 13–15°Bé., is electrolyzed for Cu recovery (various details of app. and procedure being given) and the electrolyte is then evapd. to 28°Bé. and cooled to ppt. alk. earth metal and Mg salts. It is further concd. to 38°Bé and cooled to crystallize Co sulfate, which may then be dissolved and subjected to a special electrolytic treatment to deposit Co in scales. Ni is recovered from the remaining electrolyte.

Apparatus for separating ore constituents by air currents. ALANSON O. TAYLOR. U. S. 1,792,404, Feb. 10. Various structural details are described.

Treating ores of metals. MEYER MINERAL SEPARATION CO. Brit. 336,770, Sept. 30, 1929. Metalliferous material is heated in the presence of a so-called "reagent metal" (defined as a metal capable of existing in 2 or more states of oxidation, such as Fe, Cu, Ni or Mn) to an elevated temp. somewhat below the decompn. temp. of the sulfate of the "reagent metal" and treated alternately with an oxidizing gas such as air and with an atm. contg. SO_2 and air. The process is applicable to oxidized or sulfide ores contg. Au, Ag, Pb, Ni, Mn, Cu, Co, Bi, Zn, Cd, Fe and similar heavy metals (which may themselves contain sufficient of the "reagent metal" or may be mixed with pyrites to supply the latter). If the ore is not amenable to sulfating, a halide such as NaCl may be gradually added to form chlorides. Various details and examples are given.

Treating sulfidic ores. E. J. KOHLMEYER. Brit. 336,670, July 19, 1929. Sulfidic ores of metals such as Zn, Sn, Pb, Bi, Cd, As and Sb are blast-smelted in a rotary furnace of such (described) construction that the flame is compelled to enter and leave by the same side, and air is blown on or into the melt until oxidation of the Fe present commences. In treating ore contg. pyrites and ZnS, the oxidation to ZnO supplies sufficient heat that no further external heating is required. A small proportion of lime may be added to form Ca ferrite with any Fe oxide produced and prevent stiffening of the melt, and a small proportion of coal may be added to prevent the Ca ferrite from taking up ZnO. When Fe and Cu are present, a slag contg. Cu-Ca ferrite is formed; the Cu may be sepd. as a mat from the slag by treatment with added S-bearing material such as pyrites.

Treating chromium ores. I. G. FARBENIND. A.-G. Brit. 336,970, July 22, 1929. Cr ores, such as those which are to be worked up with an alkali carbonate in the presence of lime, dolomite or bauxite, are preliminarily heated in an oxidizing atm. to above 800°, with or without adding a small proportion of an oxidizing agent such as $NaNO_3$ or KNO_3.

Treating titanium ores. MONTAN- UND INDUSTRIALWERKE VORM. JOH. D. STARCK. (Willy Glaser, inventor). Austrian 120,673, Oct. 15, 1929. Ilmenite, rutile and like ores are heated in an autoclave under pressure with an excess of H_2SO_4. The reaction product is allowed to settle, and the liquid, comprising the excess of acid with some dissolved Ti and Fe, is sepd. and used in treating a fresh batch of ore. The solid resi-

due, comprising metatitanic acid and ferro-ferric sulfate, is sepd. into its components by extn. with water or mother liquor from a previous operation.

Treatment of zinc-bearing material. WILLIAM C. HOOBY (to The New Jersey Zinc Co.). Can. 308,892, Feb. 24, 1931. ZnS concentrates contg. insol. compds. of Mg and Ca are roasted to convert the Mg and Ca into sulfates and the ZnS into ZnO, and the product is leached to remove the sulfates of Mg and Ca.

Treatment of zinc-bearing material. WILLIAM C. HOOBY (to The New Jersey Zinc Co.). Can. 308,893, Feb. 24, 1931. A pulp of Zn concentrates contaminated with insol. compds. of Mg and Ca in objectionable amts. is treated with H_2SO_4 in amt. sufficient to convert the compds. of Mg and Ca to Mg and Ca sulfates while inhibiting the formation of $ZnSO_4$; the mixt. is leached to remove such sulfates as have been rendered water-sol., and the sludge is subjected to a "hydrosepn. action" to remove undissolved $CaSO_4$ particles held in suspension.

Roasting sulfide ores such as zinc blende. METALLGES. A.-G. Brit. 335,852, June 4, 1929. See Ger. 502,586 (*C. A.* **25**, 479).

Agglomerating pulverulent hematites. BROR CHRISTIANSEN. U. S. 1,792,413, Feb. 10. The pulverulent ore is crushed to such fineness that the main portion of the mass has a grain size of 0.04 mm. or less but not a colloidal or slimy consistency, and the material thus prepd. is heated.

Coked agglomerates. EARL H. BUNCE (to The New Jersey Zinc Co.). Can. 308,891, Feb. 24, 1931. An intimate mixt. of zinciferous material and carbonaceous material with a moisture content of 6–12% of the dry wt. is initially heated by direct contact with a gaseous heated medium passed therethrough of sufficient vol. and high temp. to form promptly a shell of coke on each agglomerate, and the heating is continued until coking is completed.

Coked agglomerates. GEORGE T. MAHLER and ERWIN C. HANDWERK (to The New Jersey Zinc Co.). Can. 308,894, Feb. 24, 1931. A mixt. of zinciferous material and carbonaceous material is subjected to an initial temp. not exceeding 550° and the continued application of heat for 2–4 hrs. at temps. gradually increasing to the coking temp., whereby the agglomerates first undergo a drying stage without softening and next become plastic and finally become coked throughout. The agglomerates possess satisfactory residue strength for vertical retort smelting.

Casting metals under pressure. P. HAESSLER. Brit. 336,129, Nov. 7, 1929. App. and details of operation are described.

Continuous casting of metals between rolls, etc. H. HARRIS. Brit. 336,727, Aug. 27, 1929. Mech. features.

Casting metals with sheathings of other metals. I. SUGIMURA, K. MAGARISAWA and M. YASUMOTO. Brit. 337,286, Jan. 8, 1930. In casting a metal sheathing on a core metal having a higher m. p., lower sp. gr. and greater surface tension than the sheath metal, when the 2 metals are non-alloying with each other (as in the case of cast iron or iron alloys with Cu, Cu alloys, Pb or Sn or of Zn or Al with Pb), the melted metals are mixed in a vessel in which they assume such a configuration that when poured into a mold the core metal is suitably covered by the sheath metal. Various details of use of reducing agents, fluxes, etc., are described.

Trough for centrifugal casting machines with horizontal rotary molds. AURELIO POSSENTI and CARLO SCORZA. Ger. 516,009, July 28, 1929.

Apparatus for centrifugal casting of articles such as metal pipe. FRANK G. CARRINGTON (to Ferric Engineering Co.). U. S. 1,792,069, Feb. 10. Structural features.

Centrifugal casting of metal pipes, etc. FERRIC ENGINEERING CO. Brit. 337,105, Aug. 22, 1929. App. and various details of operation are described.

Casting metal pipes in centrifugal molds. L. A. CAMEROTA. Brit. 336,857, Dec. 5, 1929. Mech. features.

Mold for casting hollow metal bodies. MANNESMANNRÖHREN-WERKE. Ger. 513,994, Nov. 5, 1927. Details are given.

Water-cooled molds. ANTON MOHR. Ger. 513,930, Oct. 27, 1927. The molds are for casting roller plates, axles, rods and tubes.

Casting aluminum and its alloys. VEREINIGTE ALUMINIUM-WERKE A.-G. (Hans Bohner, inventor). Ger. 516,139, Sept. 7, 1929. Local variations in the compn. of the cast metal are compensated, and castings of more uniform compn. are obtained by feeding the casting with an alloy differing in compn. from the casting. Thus, an ingot may be cast from an Al alloy contg. 5.95% of Cu, and the casting fed with an alloy contg. 7.26% of Cu.

Furnace for reheating ingots. OFENBAU-GES. M. B. H. Fr. 694,653, April 28, 1930.

Furnace suitable for the heat treatment of sheet steel, etc. RALF S. COCHRAN (to Surface Combustion Co.). U. S. 1,792,074, Feb. 10.

Metallurgical furnace suitable for steel treatment and decarbonization. FRED H. LOFTUS. U. S. 1,792,021, Feb. 10.

Continuous-process furnace suitable for carburizing metal articles such as those of steel. CHARLES T. WILLARD and RICHARD KAIER (to Singer Mfg. Co.). U. S. 1,792,456, Feb. 10.

Tube or muffle furnace for heat treatment of wire. H. B. BLYTHE. Brit. 336,947, June 22, 1929.

Heat-treating furnace for enamelled articles. JOHN C. CROMWELL (to Steel Sanitary Co.). U. S. 1,792,284, Feb. 10.

Gas-heated doorless hardening furnace for tools. ERICH REIMANN. Ger. 513,601, June 15, 1928.

Apparatus for removing the products from the bottoms of blast furnaces. KOHLENSCHEIDUNGS-G. M. B. H. Ger. 513,611, June 28, 1927.

Apparatus for charging Scotch-hearth furnaces such as those used for smelting ores. HUGH R. MACMICHAEL (to American Smelting and Refining Co.). U. S. 1,791,677, Feb. 10. Structural features.

Bessemerization of mats. THE INTERNATIONAL NICKEL CO. Fr. 694,092, April 17, 1930. Mats of Ni or alloys contg. Ni such as Monel metal are bessemerized to remove S and reduce the mats by melting the mat in a convertor and introducing a mixt. of air and superheated steam. The mat is blown at a temp. of 1100–1500°, then carried to a temp. of 1500–1600° while continuing the blowing, the blowing mixt. being then almost completely free from air or O.

Reducing metallic compounds. GUSTAF N. KIRSEBOM. Fr. 694,283, April 22, 1930. Metallic compds. are reduced by the reaction of As on a molten alkali metal compd. such as NaOH, in the presence of the metallic compds. to be reduced. Pb, Cd, Sb and Bi may be obtained in this way from their oxides.

Extrusion manufacture of metal tubes, etc. P. MULTHAUPT. Brit. 336,688, July 26, 1929. In effecting the extrusion of liquid or plastic iron, steel or other metal, the matrix, mandrel, dies, etc., are formed of W or of an Fe-free alloy of W with C, Si, Zr and "metals analogous to W." Scale is removed by heated or high-pressure gases.

Apparatus for cutting metals by fusion. L. J. HANCOCK. Brit. 336,433, Oct. 15, 1929. Structural features.

Apparatus for washing thin metal sheets. FRITZ GRAH. Ger. 516,208, Jan. 11, 1929.

Finely divided metals from carbonyls. I. G FARBENIND. A.-G. Brit. 336,007, July 10, 1929. See Fr. 690,991 (*C. A.* **25**, 1211).

Metal acetylides. DEUTSCHE GOLD-UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Brit. 336,516, Feb. 7, 1929. Acetylides such as those of the alkali metals or their alloys with each other are made by continuously exposing fresh surfaces of the molten metals or alloys to the action of C_2H_2 (suitably in a rotating tube from which the air has initially been displaced by N). For making mono-Na acetylide, 60 hrs. are required at a temp. of about 170 80°; for di-Na acetylide, a temp. of 210-20° is used.

Aluminum salts. E. HERZFELD and H. WALKER (to Colloid-chemische Forschungs A.-G.). Brit. 336,181, Jan. 7, 1929. Fe-free Al salts such as the sulfate are obtained from Fe-bearing solns. by pptn. with alc. The soln. and pptn. may be repeated.

Dezincing lead. JESSE O. BETTERTON (to American Smelting and Refining Co.). U. S. 1,792,210, Feb. 10. Precooled Cl gas is confined in a reaction tank, and molten lead to be dezinced is continuously recirculated through the Cl while maintaining the lower end of the tank sealed by the metal of the bath outside the tank to prevent escape of the Cl. App. is described.

Tin. WALTER POETSCH and ROMAN VON ZELEWSKI. Ger. 513,697, Aug. 15, 1928. Sn is obtained from raw material by heating it to 250° with NaSH. Aq. tech. NaSH soln. may be employed. In the example, zinc blende contg. about 10% Sn is heated with a 25% soln. of NaSH.

Tungsten. A. PACZ. Brit. 337,160, Oct. 3, 1929. In forming W ingots by compacting W powder and sintering, freedom from residual O is insured by mixing the powder with a more volatile metal such as Ag, compacting, sintering and volatilizing the added metal such as Ag to form a pure unworked W ingot suitable for use in the manuf. of filaments, spark points, elec. contacts, etc. Various methods are described involving admixt. of W and Ag compds., with or without a Th compd., followed by reduction and by volatilization of the Ag. Cf. *C. A.* **24**, 5280.

Finely divided metals such as combined zinc and copper. WM. C. WILSON. U. S.

1,792,262, Feb. 10. A metal such as Cu is reduced from one of its salts such as $CuSO_4$ by effecting intimate contact of the salt in a dispersed state with a precipitant metal (such as Zn in the case of $CuSO_4$), and the particle size of the liberated metal is controlled by the degree of comminution (less than 40 mμ) of the precipitant metal.

Magnetic testing system for testing materials such as sheet iron or steel, electric coils, etc. JAMES T. SERDUKE (to General Elec. Co.). U. S. 1,792,249, Feb. 10.

Rolling sheet, hoop or band iron. FRANZ JORDAN. U. S. 1,792,377, Feb. 10. Various mech. details are described for rolling an iron core between covering sheets of Al so thin that under the high roll pressures employed the Al is driven substantially completely into the pores of the iron core and forms substantially no exterior plating on the iron.

Iron and steel. H. HAGEMANN. Brit. 336,954, July 18, 1929. In producing a non-siliconized iron or steel which can be easily welded, the C content of the bath is reduced (suitably to about 0.02%), and there is afterward added, in the furnace or ladle, an Al-Si alloy of such compn. that it readily slags off. Mn low in C may be added to facilitate working of the product, and the latter may contain C 0.02, Mn 0.5, Cu 0.09, P 0.02 and S 0.003%. The Al-Si alloy added may contain Al 30, Si 50, Fe 19 and C 0.25%, or an alloy may be used contg. Al 18–22 and Si 40–50%. Cf. *C. A.* **24**, 2102.

Steel. POLDIHÜTTE. Austrian 120,668, May 15, 1927. Steel resistant to corrosion and capable of being forged contains C 0.2–1, Ni 20–25, Cr 12–20, Mn less than 0.5 and Si less than 0.5%, specifically C 0.5, Ni 22, Cr 15, Mn 0.4 and Si 0.3%.

Steel. ANDRÉ P. MAHOUX. Fr. 695,045, Aug. 8, 1929. Steels are hardened superficially by creating an oscillating field between the metallic piece and the piece to be treated, the dielectric being composed of a carbureted or N atm.

"Stainless steel," etc. W. E. MARTIN and J. A. BERLYN. Brit. 336,024, July 22, 1929. "Stainless steel" and similar Fe alloys contg. high proportions of Cr or Ni (or mixts. of metals adapted to form such alloys) are melted in a crucible in a furnace, the temp. of which is increased gradually and substantially uniformly to the casting temp. (especially at the temp. range between 900° and the casting temp., which may be 1800–2400°). The heating may be at the rate of 100–400° per 15 min. Deoxidants such as Al may be added, together with other materials such as Cr hydrate if desired, just before casting, and the metal may be cast into molds made of 2 parts molding sand and 1 part sea sand bonded with molasses, the cores being formed of molding sand 1 and sea sand 2 parts.

Manganese steels. TAYLOR-WHARTON IRON & STEEL CO. Brit. 336,091, Oct. 4, 1929. Steels contg. Mn 10–15% and C 0.3–0.85% also contain up to 4% Ni and less than 0.4% Si, with or without 8% or less of Cr, and may be toughened by heating to 800–1150° and cooling in air.

Case-nitridation of steel. AUGUSTUS B. KINZEL (to The Electro Metallurgical Co. of Can., Ltd.). Can. 309,049, Mar. 3, 1931. An article of ferrous material is heated to 700° for 2 hrs. in the presence of H, then heated in the presence of V to 900° for 2 hrs., and then heated in the presence of NH_3 to 500–580° for a time sufficient to make a hard surface layer on the article.

Case-hardening by nitridation. AUGUSTUS B. KINZEL (to The Electro Metallurgical Co. of Can., Ltd.). Can. 309,047, Mar. 3, 1931. Ferrous material is heated with Al to about 550° to form an aluminized coating and then subjected to a temp. of about 510° in the presence of NH_3.

Case-hardening by nitridation. AUGUSTUS B. KINZEL (to The Electro Metallurgical Co. of Can., Ltd.). Can. 309,048, Mar. 3, 1931. Fe and steel articles (contg. alloying elements as Mn, Si, Cr and particularly V and Al) are case-hardened by heating in a molten nitriding bath contg. one or more metal cyanides (as mixts. of NaCN and KCN, of NaCN and $Zn(CN)_2$, or of KCN and $Mg(CN)_2$) at a temp. below 580°.

Alloys. W. C. HERAEUS G. M. B. H. Ger. 516,490, May 20, 1930. Addn. to 437,173. Ger. 437,173 describes alloys for making pen nibs comprising Ru 40–60, Os 35–50 and Pt 5–15%. There are now used alloys contg. Ru 60–80, Os 10–35 and another metal of the Pt group 5–25%.

Alloys. THEODOR KITTL. Austrian 120,383, July 15, 1930. In fractionally crystg. fused alloys so as to obtain alloys of different compn., the melt is slowly circulated during the crystn., with the result that larger crystals are obtained. Circulation may be effected by elec. induction heating.

Alloys. WALTHER MATHESIUS and MARTIN W. NEUFELD. Ger. 513,623, April 27, 1926. Addn. to 441,071. Pb is hardened by adding alkali or alk. earth metal, Mg or Al and 0.1% Bi, Cu or Sn. The Pb alloy may contain 0.6 to 0.65% Na, 0.75

to 0.1% Ca, 0.2 to 0.25% Mg and 0.10% Al, the ratio Ca:Mg:Al being kept at the value 8:2:1.

Alloys. KARL SCHMIDT G. M. B. H. Ger. 516,200, Aug. 27, 1926. Al alloys for making pistons contain Si 20–35 and Cu up to 5, with or without Mg and (or) Mo up to 5%. Cf. *C. A.* **24**, 3982.

Alloys. GEORG WECK. Ger. 513,513, Sept. 7, 1929. Objects resistant to HCl and H_2SO_4 are made from alloys contg. NiSb 0.5 to 70, Ni 0 to 30 and W or Mo 69.5 to 0%. The NiSb may be replaced wholly or partly by W.

Alloys. THE INTERNATIONAL NICKEL CO., INC. Fr. 694,929, April 12, 1930. Alloys which are resistant to corrosion contain Fe 20–80, Ni 12–79, C 0.01–2 and Cu 1–32%. An example contains Cu 6, Ni 34, Fe 60 and C 0.2%. Fr. 694,930 describes an alloy contg. Cu 1–20, Ni 12–30, C 0.01–2% and Fe the rest An example contains Ni 25.5, Cu 4.5, Mn 0.6, C 0.1% and Fe the rest. Cf. *C. A.* **25**, 677.

Alloys. SOC. DES TORPILLES DE ST. TROPEZ. Fr. 695,050, Aug. 9, 1929. An alloy for protecting Fe, etc., against corrosion contains Cd and Sn, Cu and Pb or Sb being optional addns. An example contains Cd 10, Cu 10, Sn 60 and Pb 20%.

Alloy for bearing surfaces. H. C. HALL. Brit. 336,881, Dec. 30, 1929. "Commercial Zn" is alloyed with Al 8–18, Cu and Ni up to 1% each and preferably only traces of other metals. The Zn is added after melting the other metals together.

Alloy for jewelry. VICTOR WYLDES. Can. 308,834, Feb. 24, 1931. To 5 lbs. 10 oz. of melted Cu are successively added 3 oz. fuller's earth, 7 oz. $Na_2B_4O_7$, 3 oz. ammoniated mercury, 12 oz. Sn, 3 oz. MgO and 1 oz. alc., and the mixt. is agitated and boiled. The resultant alloy simulates Au and is malleable, ductile, immune from tarnishing and suited for jewelry.

Alloys for sealing to glass such as in vacuum tube and incandescent lamp manufacture. N.-V PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 337,086, Aug. 6, 1929. Ring- or disk-shaped members of metal to be sealed to material such as glass are formed of an alloy contg. Ni (preferably over 50%) together with other metals such as W, Mo, Ta, V, Nb, Co or Si, the coeff. of expansion of the alloy being at least approx. equal to that of the insulating material with which the alloy is to be sealed. One or more substances such as Cr, Al or Mg which facilitate the formation of a coherent film of oxide may be added to the alloy in proportion preferably less than 5%.

Magnetic alloys. W. S. SMITH, H. J. GARNETT and W. F. RANDALL. Brit. 336,948, June 22, 1929. Alloys substantially free from C and composed mainly of Fe and Ni are given a high and const. permeability by heating to 900° or over until completely annealed, cooling and further heating to not over 700° but to at least 50° above the magnetic change point of the alloy (and in the case of alloys contg. not more than 50% Ni preferably at least 100° above the change point). The alloy is preferably subjected to mech. straining between the 2 heat treatments, and the sp. resistance of the alloy may be increased by the addn. of up to 10% of one or more of the elements: Mn, Cr, Cu, Mo, W, V, Al or Si. Various details and examples are given. Cf. *C. A.* **24**, 1074.

Aluminum alloys. H. T. TILLQUIST and J. HARDEN. Brit. 337,099, Aug. 17, 1929. See Fr. 680,959(*C. A.* **24**, 3983)

Alloys of copper. P. M. G. METAL TRUST, LTD Fr. 690,875, July 26, 1929. Cu alloys are made by adding to Cu or a Cu alloy a hardening alloy contg. Fe, Si and Cu. The Fe constituent of the hardening alloy may be obtained by alloying steel and cast Fe, and the steel may include one or more of the metals Ni, Cr, Mo, W and V. The hardening alloy may also contain Mn or P or both. Examples are given. Cf. *C. A.* **24**, 5712.

Copper alloys. VICKERS-ARMSTRONGS, LTD., W. MACHIN and W. B. O'B. GOUDIELOCK. Brit. 335,950, April 4, 1929. Alloys such as those of high Cu content are made by adding to Cu or a Cu alloy a hardening alloy comprising Fe, Si and Cu (which may be prepd. in part from steel contg. also Si, Cr, Mo, W or V), and Mn and P also may be present in the hardening alloy. Various details are given, and a final alloy may comprise Cu 88, Zn 2 and hardening alloy 10%. The alloys may be heated to over 800° and quickly cooled in water or oil, in some cases being reheated to not over 450°.

Copper alloys containing tin and zinc. MICHAEL G. CORSON (15% to George H. Corey). U. S. 1,792,146, Feb. 10. Alloys of Cu contg. also Sn 4–18 and Zn 10–35% are treated, to improve their properties as lubricated wearing surfaces, by heating for a proper time and at a suitable temp. to bring about a uniform β-state of the alloy constituents, then quickly cooling to produce a hard acicular structure, reheating to a temp. above the eutectoidal transformation point for the alloy to produce a structure characterized by the presence of β-crystals uniformly distributed throughout a matrix of α-crystals, and then cooling to effect stabilization.

Magnesium alloys. I. G. FARBENIND. A.-G. Brit. 336,019, April 25, 1929. Products such as high-percentage Mg alloy castings are improved by heating at a temp. range in which the soly. of the alloying component or components is increased and then subjecting them to cooling which is considerably retarded artificially especially in the range 300–100°. Details are given of the treatment of Mg-Al alloys contg. 7.5% or more Al, Mg-Zn alloys contg. 1.8% or more Zn, and Mg-Pb alloys contg. 18% or more Pb. An alloy contg. 8.2% Al may be heated to 410° for 72 hrs., then transferred to an annealing furnace and cooled down to 100° in 24 hrs. (the cooling from 300° to 100° taking 18 hrs.).

Magnesium and its alloys. I. G. FARBENIND. A.-G. Brit. 336,498, Jan. 2, 1929. Mg and Mg alloys are refined by treating the molten metal with a material such as Mn, Cr, Mo or Si which on cooling combines with impurities such as Fe for sepn. from the remaining melt. A small proportion of the added reagent such as Mn may remain in the product. Cf. *C. A.* **25**, 678.

Preventing corrosion of aluminum. G. ADOLPH. Brit. 336,854, Nov. 29, 1929. To prevent attack of Al by alk. solns., such as alk. bleaching liquors, the latter are admixed with an alkali silicate, H_2O_2, compds. such as Na perborate or percarbonate, or mixts. of these.

Rust prevention. KARL DAEVES. Fr. 693,905, April 14, 1930. The formation of white rust on galvanized objects or other metallic surfaces is prevented by exposing the surfaces to the action of free air or the gases produced by the combustion of S before storing in closed spaces.

Rustproofing iron. W. BÖHMER. Brit. 335,868, Jan. 27, 1930. The cleaned surfaces are treated either with (1) a mixt. of Pb_3O_4, PbO, glycerol and waterglass, or (2) a mixt. of zinc white and waterglass, or (3) a $ZnCl_2$ soln. Specific formulas are given.

Rustproofing iron and steel by coating with phosphates. VAN M. DARSEY (to Parker Rust-Proof Co.). U. S. 1,791,715, Feb. 10. An iron or steel surface carrying a phosphate coating contg. a metal such as Cu having a potential different from that of iron or steel is treated with a soln. of a material contg. the chromic acid radical such as K chromate

Welding aluminum-steel. H. J. SCHIFFLER. Brit. 336,195, March 25,1929. Scale-resisting steels contg. Al (and which may also contain other components such as Cr and Mo) are welded by electrodes or rods of scale-resisting steel alloys not contg. Al (but which may contain Cr, Ni and Mo) in order to produce a scale-resisting weld. Various formulas of alloys used are given.

Welding bronze. L. J. TIBBENHAM. Brit. 336,402, Oct. 1, 1929. A welding rod for use in welding bronze by the blow-pipe flame is formed of bronze with a coating such as H_3BO_3 49, Na borate 9, metal oxides such as those of Fe and Cu 30 and Na silicate 12 parts.

Welding magnesium and its alloys. I. G. FARBENIND. A.-G. Fr. 694,137, April 18, 1930. See Ger. 508,352 (*C. A.* **25**, 680).

Electrodes for spot-welding copper. F. KRUPP A.-G. Brit. 335,876, March 26, 1929. Electrodes are used contg. one or more carbides of W or similar high m. p. metal, and they may also contain a small quantity of metals such as Fe, Co or Ni of lower m. p., *e. g.*, 6% of Co. The material sold under the name "Widia" is suitable.

Weld iron. ARTURO DOSSMANN. Ger. 513,732, April 27, 1928. Small iron waste is used as starting material and is prevented from oxidation by a coating of colophony or molasses before mixing with the wood charcoal or soot and limestone.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Catalytic addition of gaseous hydrochloric acid to unsaturated hydrocarbons. W. J. PIOTROWSKI AND J. WINKLER. *Przemysl Chem.* **15**, 25–36(1931).—The 20–40° fraction of cracked benzine was used as the starting point for this synthesis. It was characterized by n_4^{15} 0.632, amylene content 31% by wt. Its complete distn. curve at 1° intervals is given. Two hundred-cc. portions of this pentane-amylene fraction with slight excess of HCl were passed over catalysts through a glass app. for 4 hrs. The yield was figured on the basis of change in d_4^{15} and distn. fractionation. It was found advantageous to pass the raw materials over the catalysts held in 2 tubes, the 1st of which was kept at 70° and the 2nd at 150°, in which case a predominance of secondary chlorides was ob-

tained. If the sequence of these temps. was reversed a mixt. of all possible chlorides resulted. The presence of moisture interfered with the formation of secondary chlorides, and its absence never had any detrimental effects. The catalysts here studied were the chlorides of bivalent, tervalent and quadrivalent metals mounted on activated charcoal and dried at 150° for several hrs. to const. wt. The catalysts themselves caused no polymerization in the benzine in the absence of HCl. The reaction between HCl and the hydrocarbons was vanishingly small without the catalysts; it was marked in the presence of activated charcoal. The catalysts are classified in 3 groups: (1) $CrCl_3$ and $FeCl_3$, which are inactive; (2) $HgCl_2$, $CuCl_2$, $CdCl_2$, $MnCl_2$, $BiCl_3$, $AlCl_3$ and $SbCl_3$, which are slightly active; (3) $ZnCl_2$ and $SnCl_4$, both of which are strongly active, $SnCl_4$ having given a practically quant. formation of amylene monochlorides. The catalysts are subject to poisoning by S compds. which should be removed by activated charcoal previously partially poisoned. Sharp fractionation of the product showed it to be composed of Me_2CClEt, $Me_2CHCHClMe$, MeCHClPr and $Me_3CCHClMe$. A. C. Z.

Transformation of propylene into liquid hydrocarbons. A. Mailhe and Renaudie. *J. usines gaz* **54**, 568–9; *Compt. rend.* **191**, 851–4(1930); cf. *C. A.* **24**, 5283.—C_3H_6, heated over SiO_2 gel at 650°, furnishes a considerable proportion of liquid hydrocarbons, unsatd. and aromatic; C_6H_6 and PhMe predominate. Solid hydrocarbons, $C_{10}H_8$, $C_{14}H_{10}$, etc., were absent, their formation beginning at 700–20°. Traces of Fe led to excessive formation of C and inactivation of the catalyst. K. H. Engel

Synthesis of squalene. P. Karrer and A. Helfenstein. *Helv. Chim. Acta* **14**, 78–85(1931).—In a recent paper Karrer (*C. A.* **25**, 519) suggests the sym. formula $(Me_2C{:}CHCH_2CH_2CMe{:}CHCH_2CH_2CMe{:}CHCH_2)_2$ (I) for squalene rather than those proposed by Heilbron (*C. A.* **23**, 3702). Such a structure may be considered as made up of isoprene residues and in this way looks plausible in the light of the Karrer proposed structure for lycopin and carotene. On the assumption of the above structure K. and H. synthesized I by treating farnesyl bromide, $Me_2C{:}CHCH_2CH_2CMe{:}CHCH_2CH_2CMe{:}CHCH_2Br$ (II) with K or Mg, whereby 2 mols. of II were joined through the elimination of Br from each. The synthetic I forms a mixt. of 2 isomeric hexahydrochlorides with HCl as does I from natural sources. These hydrochlorides may be sepd. by hot acetone into a hexahydrochloride m. 143–5° (0.25–0.20 part) and one m. 108–10°, exactly as may be done when they are prepd. from natural I. Crystals of the hexahydrochloride m. 143–5° from synthetic source were compared with those from a natural source and in both cases rhombic forms, chiefly $m(110)$ and $c(001)$ and seldom $b(010)$, were observed. The angle (110):(110) is about 59° so that $a:b = 0.56:1$ in both. Optical orientation $n_\alpha \| b$, $n_\beta \| a$, $n_\gamma \| c$; optical character, neg. X-ray absorption of the powder of both prepns. gave 11 lines with Fe-K radiation which agree in position and intensity. The yields of I were poor (about 5%) because K. and H. could not prep. pure II. Probably the difficulty is due to the known tendency of halogen in similar compds. to migrate to a tertiary C atom or the reverse: $-MeC{:}CHCH_2Br \rightleftharpoons -MeCBrCH{:}CH_2$. In agreement with this assumption it was possible to prep. from nerolidol, $Me_2C{:}CHCH_2CH_2CMe{:}CHCH_2CH_2CMe(OH)CH{:}CH_2$ (III), a mixt. of Br compds. which yielded I on treatment with K or Mg. K. and H. regard I as a possible mother substance of cholesterol (cf. André and Canal, *C. A.* **23**, 3364). Ten g. of farnesol (IV) or III (3 mol.) was added dropwise to a mixt. of 1 g. dry pyridine ($^2/_3$ mol.) and 5 g. PBr_3 (1.2 mols.) at —5° and allowed to stand overnight at room temp., washed with ice-cold $NaHCO_3$ soln. and extd. with ether. The ether soln. was washed successively with dil. H_2SO_4, $NaHCO_3$ and water, then dried and distd. A fraction $b_{0.7}$ 110–20° with 8.1% Br and one $b_{0.6}$ 125–300° (about 9 g.), with 17.3% Br were collected. Redistn. caused decompn. and lowering of the Br content This impure bromide (V) was used although the theoretical percentage of Br is 28.07. Other methods of bromination or chlorination of III or IV gave poorer yields of less pure material. Into 9 g. crude V at 100° was dropped 3 g. K and the temp. raised to 135° for 0.5 hr.; the cold product was treated with abs. ether and excess K removed by filtration through glass wool. The soln. was washed with dil. H_2SO_4 and then with water, dried and distd. The fractions sepd were one of 3.5 g., b_1 100–20°, the squalene fraction of 2 g., b_1 210–40° and a residue of 1.5 g. which yielded no squalene hexahydrochloride (VI) with HCl. The 2-g. squalene fraction yielded 0.05–0.15 g. of VI on treatment with HCl. Impure V (15 g.) was treated with 1.7 g. Mg and yielded 3 g. impure I, which on conversion to VI gave 0.55 g. Impure V (28 g.) treated with 2.7 g. Mg yielded 6.8 g. I and this gave 1.3 g. VI. One g. squalene, from natural sources gave 0.5 g. VI; if the Br content of V is taken as a basis of its purity the yield of I from pure V is about 20%. Oden E. Sheppard

Catalysis of polymerization by ozonides. Ray C. Houtz and Homer Adkins. *J. Am. Chem. Soc.* **53**, 1058–63(1931).—A mixt. of the ozonides of 2 octylenes has

been found to catalyze the polymerization of styrene, indene, $(CH_2:CMe)_2$, a methylpentadiene and furfuryl alc. It has been found to be inactive as a polymerization catalyst toward stilbene, *o*-$HOC_6H_4CH_2OH$, $Me_2C:CHMe$ and the mixt. of octylenes from which it is made. The catalyst was active at room temp. and 100° and in a soln. in PhMe. The ozonide underwent a change on standing, especially during the first 2 days after its prepn., and lost a large part of its catalytic power. C. J. WEST

The halogenation of the paraffin hydrocarbons. GUSTAV EGLOFF, R. E. SCHAAD AND C. D. LOWRY, JR. *Chem. Reviews* **8**, 1–80(1931).—A summary of the work which has been done on the halogenation, particularly the chlorination and bromination, of paraffin hydrocarbons. An extensive bibliography is given. Problems for research are suggested. LOUISE KELLEY

Preparation of alkyl iodides. HAROLD S. KING. *Proc. Trans. Nova Scotian Inst. Sci.* **17**, 242–3(1930).—In the prepn. of alkyl iodides by a modification of Adam's method the use of anhyd. alc. is not necessary (*Proc. Trans. Nova Scotian Inst. Sci.* **16**, 87–91(1924). The addn. of 10% by wt. of water to MeOH did not reduce the yield of MeI. A MeOH soln. of I is slowly run into the reaction flask contg. P and more MeOH and heated at 70–5°. The refluxing liquid passes over I on its return to the flask. RACHEL BROWN

Preparation of anhydrous alcohol, and the detection and determination of water in alcohol. F. ADICKES (WITH W. BRUNNERT AND O. LÜCKER). *Ber.* **63B**, 2753–60 (1930).—When HCO_2Et is added to alc. NaOEt it is almost instantly sapond. in the cold by the slightest traces of water in the alc. according to the equation $HCO_2Et + NaOEt + H_2O = 2HOEt + HCO_2Na$, with pptn. of the very difficultly sol. HCO_2Na. As HCO_2Na can be detd. easily and accurately the reaction can be used for the 3 purposes indicated in the title. After this work had been started, it was found that Smith had made use of the same principle, employing $(CH_2CO_2Et)_2$ instead of HCO_2Et (*C. A.* **21**, 3328). $(CH_2CO_2Et)_2$ is much more difficult to saponify than HCO_2Et and the anhyd. alc. he prepd. by its means contained 0.04 g. of the ester per l. With HCO_2Et, the equil. in the catalytic decompn. of HCO_2Et by alc. NaOEt (HCO_2Et = CO + HOEt) lies practically completely on the CO side at the b. p. of the alc., and by using an excess of NaOEt, refluxing until equil. is established and distg. away a first fraction, an alc. can be obtained whose ester content is at least 10 times less than that of the alc. obtained with $(CH_2CO_2Et)_2$. When neutral HCO_2Na is boiled a long time with alc. and the alc. is then slowly distd. off, the residue becomes slightly alk. because of loss of HCO_2H as HCO_2Et; the alky. corresponds to 0.0037% ester in the alc. distd. off, or a water content of only 0.0009%. The process for prepg. anhyd. alc. consists simply in dissolving Na in the alc., adding HCO_2Et, heating under a reflux until no more CO is evolved and then adjusting the cooling water in the reflux so that the alc. distils off. The alc. so obtained contains 0.03% water and 0.00015% HCO_2Et. The soly. of HCO_2Na in alc. in the presence of NaOEt is so small at 0° (0.05 in 100 g. alc.) that by addn. of NaOEt soln. and HCO_2Et as little as 0.013% water in alc. can be detected qualitatively by the turbidity produced. For quant. detns., the HCO_2Na can simply be filtered off when the quantity of water is large (2.5–3%); with smaller quantities of water the alc. and undecompd. ester must be distd. off (finally *in vacuo*); with very small quantities of water (0.1%) there must be applied a correction factor for the water or acid content of the HCO_2Et, detd. by running parallel detns. with different quantities of HCO_2Et. The HCO_2H was detd. by weighing the HgCl pptd. from $HgCl_2$; the detn. cannot be carried out in alc. since the latter also reduces $HgCl_2$, although but slowly. With the larger quantities of water the detn. can be made volumetrically by filtering off the HCO_2Na and titrating it with an oxidizing agent. The detn. can also be made by using a known quantity of HCO_2Et and measuring the CO evolved by decompn. of the excess; in this case allowance must be made for the ester vapors carried along by the CO and for the water and acid content of the HCO_2Et, and the method is accurate enough only for water contents of 1% or more. C. A. R.

Preparation of absolute ethyl alcohol. E. GORDON YOUNG. *Proc. Trans. Nova Scotian Inst. Sci.* **17**, 248–55(1930).—A comparative study has been made, with reference to % yield and cost per l. of product, of 3 methods of prepg. abs. alc. for ordinary chem. procedures. By the carbide method (1) 100 g. 95% alc. was refluxed 2 hrs. with 25 g. CaC_2 and 1 hr. further with 1 g. $CuSO_4$. A 2nd treatment with $CuSO_4$ was necessary to remove odors. The yield was 95% of 99.7% alc. By the C_6H_6 method (2) 2000 cc. alc. and 1500 cc. C_6H_6 were distd. in a fractionating column with 22 bulbs; 300 cc. abs. alc. was obtained. By the CaO method (3) alc. was refluxed with varying amts. of CaO for varying periods of time. The time required was found to vary inversely with the amt. of CaO used. 1 l. 95% alc. refluxed with 300 g. fresh CaO for 4 hrs. gave an

80% yield. Conclusion: method 1 gives the best yield at a cost slightly higher than 3; method 2 is impracticable on a lab. scale; method 3 is the cheapest. R. B.

Organic compounds of thallium. R. C. MENZIES. *Chem. News* **141**, 305–6 (1930).—The Tl′ atom replaces the H of many OH compds., including simple and polyhydric alcs. of the aliphatic series, with the formation of stable compds. which are generally less sol. than those of the alkali metals. In many cases all the H of the OH of the polyhydric alcs. and the H of the OH and the CO_2H of the HO acids can be replaced, but well-defined Tl salts of the reducing sugars have not yet been prepd. because of the oxidation of the sugars with the reduction of the metal. However, with compds. in which the reducing groups are protected, well-defined Tl derivs. are obtained, although with α- and β-Me glucosides 1 of the 4 available H escapes replacement and with sucrose only 4 of the 8 available H are replaced. An explanation of these observations has not yet been found. C. J. PEDERSEN

Catalytic hydrogenation of esters to alcohols. HOMER ADKINS AND KARL FOLKERS. *J. Am. Chem. Soc.* **53**, 1095–7(1931).—Et laurate, myristate, valerate, cinnamate, trimethylacetate and succinate have been hydrogenated over a Cu chromite catalyst with the formation of the corresponding alcs. in yields of 80–98%. The CO_2Et group in $HOCH_2CMe_2CO_2Et$ was hydrogenated to a CH_2OH group, and in addn. the mol. underwent cleavage between the 2 and 3 C atoms. The H pressure during the hydrogenation approximated 220 atm. and the temp. was 250°. C. J. WEST

Esters of sulfurous acid. I. WALTER VOSS AND ERICH BLANKE. *Ann.* **485**, 258–83(1931); cf. *C. A.* **25**, 69.—Dropping 1 mol. MeOH into 1 mol. $SOCl_2$ cooled in ice and salt and simultaneously passing through a rapid stream of CO_2 to stir the mixt. and remove HCl as formed, gives 50% of *Me chlorosulfinate*, MeOSOCl, b_{60} 35°, d_4^{18} 1.4186, slowly decomposing at room temp. into MeCl and SO_2 and immediately decomposed by water. *Et ester*, b_{16} 32°, b_{24} 41–2°, d_4^{17} 1.2826 (68% yield); *iso-Pr ester*, $b_{24.5}$ 34°, d_4^{16} 1.2005 (47% yield). $SOCl_2$ and 2.2 mols. MeOH with cooling give 70–5% $(MeO)_2SO$, b_{760} 126°, d_4^{24} 1.2073; di-Et ester, b_{760} 158° (85% yield); Pr ester, b_{760} 192–2.5°, b_{15} 89° (90% yield); boiling 24 hrs. causes little change; iso-Pr ester, b_{20} 78°, b_{765} 169.5–70.5° (33% yield); *Bu ester*, b_{15} 114–5°, d_4^{22} 0.9944, $n^{19.8}$ 1.430511, 1.43808, 1.44268 for α, β and γ, n_D^{11} 1.43244 (94% yield); *iso-Am deriv.*, b_{15} 127–8°, $d_4^{16.2}$ 0.97293, $n^{12.4}$ 1.43547, 1.44315, 144820, 1.43757 for α, β, γ and D (72% yield); *cyclohexyl ester*, b_{19} 182°, $d_4^{17.8}$ 1.0974, $n^{18.7}$ 1.48396, 1.49571, 1.4865 for α, β and D (54% yield); *di-Ph ester*, $b_{0.7}$ 143°, $b_{1.8}$ 152°, $d_4^{19.2}$ 1.2404, $n^{18.4}$ 1.56899, 1.58833, 1.57441 for α, β and D (34% yield). EtOSOCl and the calcd. amt. of MeOH and C_5H_5N give *Me Et sulfite*, b_{20} 53°, b_{769} 141.5°, d_4^{18} 1.1364, $n^{19.8}$ 1.41417, 1.42159, 1.42628, 1.41669 for α, β, γ and D. If C_5H_5N is not used, a mixt. of Me_2SO_3, Et_2SO_3 and $MeEtSO_3$ results. Me_2SO_3 (0.2 mol.) and EtOH (1 mol.) with 0.1 cc. 12% EtOH-HCl as a catalyst, give 44% of Et_2SO_3. Similarly Et_2SO_3 and MeOH give Me_2SO_3. $MeOS(O_2)Me$ results in 67% yield from $MeSO_3H$ and MeI at 100°; b_{25} 101–2°, b_{751} 202–3°, d_4^{21} 1.2975, $n^{17.6}$ 1.41384, 1.42027, 1.41576 for α, β and D. The kinetics of the hydrolysis of $MeOSO_2Me$ and Me_2SO_3 by water, acid and alkali are discussed. The following values were obtained for pure water ($H^+ = 1$) and ($OH^- = 1$): $MeOSO_2Me$, 2.98×10^{-4}, 0, $2.81 \times 1\ 0^{-2}$; Me_2SO_3, 0, 1.30×10^{-2}, 13.37; Et_2SO_4, 1.55×10^{-3}, 0, 9.5×10^{-3}; Me_2CO_3, 0, 0, 5.4. The Na derivs. of PhOH, *o*-$O_2NC_6H_4OH$ and β-$C_{10}H_7OH$ with 1.1 mols. dialkyl sulfite give: 80% PhOMe, 88% β-$C_{10}H_7OMe$, 85% *o*-$O_2NC_6H_4OMe$, 88% PhOPr, 55% iso-AmOPh. With 3 mols. Me_2SO_3 the *o*-, *m*- and *p*-$C_6H_4(OH)_2$ give 89, 76 and 80% of the di-Me ethers, resp. PhOH and Me_2SO_3 with a few drops concd. H_2SO_4 or EtOH-HCl give 9.3% PhOMe; β-$C_{10}H_7OH$ gives 37% Me ether and 63% Et ether. One mol. $PhNH_2$ with the dialkyl sulfites gives the following yields of alkyl derivs.: 96% $PhNMe_2$; 52% $PhNEt_2$, 31% PhNHEt; 38% $PhNPr_2$, 44% PhNHPr; 15% $PhN(iso\text{-}Am)_2$, 74% PhNH(iso-Am). *Benzenesulfonethylanilide*, $b_{1.5}$ 188.5°, d_4^{21} 1.1943, $n_D^{16.3}$ 1.57537; *p-toluenesulfonisoamylanilide*, m. 76–7°. $PhNMe_2$ and Me_2SO_3, heated at 135–40°, give 99% of *trimethylphenylammonium methanesulfonate* (I), $(PhNMe_3)OS(O_2)Me$, m. 188–9°; this also results from $PhNMe_2$ and $MeOSO_2Me$ at room temp.; on warming 24 hrs. with 12% KOH 53% of $PhNMe_2$ are split off; 5% MeONa splits off 96.5% in 5 hrs. $PhNMe_2$ and Me_2SO_3 on standing at room temp. for several weeks deposited 10% of a yellow, very hygroscopic product, m. 120–1°, which may be $(PhNMe_3)OSO\text{-}OMe$; this could not be changed into I by heating at 135°. *N-Methylpyridinium methanesulfonate*, red, very hygroscopic, m. 117–8°; C_5H_5N and Me_2SO_3 at room temp. give the compd., $C_7H_{11}NO_3S$, m. 104–7°. The following yields of esters were obtained with

1.1 mols. dialkyl sulfite and a drop of concd. H_2SO_4 on warming 1–2 hrs.: BzOEt 96; BzOBu 86; *p*-$BrC_6H_4CO_2Et$ 95; $PhCH:CHCO_2Et$ 86; $MeCH:CHCO_2Me$ 82; $(CH_2CO_2Et)_2$ 90; $CH_2(CH_2CO_2Et)_2$ 81; salol, 65; di-Et carbonates do not give esters under these conditions. **II. Preparation of acetals and glucosides.** W. Voss. *Ibid* 283–98.—Cyclohexanone (I) and Me_2SO_3 in MeOH, with MeOH-HCl as a catalyst, gave 79% of the *di-Me acetal*, $b_{22.5}$ 64°. In the same way PrCHO gave 87% of the di-Me and 72% of the di-Et acetals; BzH gave 81% di-Me and 78% di-Et acetals; *p*-$MeOC_6H_4CHO$ gave 84% di-Me acetal and I gave 63% of the di-Et acetal. These new acetals will be described later. Ph_2CO and Me_2SO_3 gave 95% of di-Me acetal, m. 106–7°. BzH (10.5 g.), 12 g. Me_2SO_3 and 27 g. BuOH (with MeOH-HCl) gave 80% of *benzaldehyde di-Bu acetal*, b_{14} 149–50°, d_4^{14} 0.9289, n_D^{19} 1.4790. The di-iso-Am acetal was obtained in 76% yield. The following yields of $Ph_2C(OMe)_2$ were obtained from 4.6 g. Ph_2CO with 0.1 mol. reagent in MeOH with HCl as catalyst: Et_2SO_3 1.9 g.; $HC(OEt)_3$ 2.9 g.; $HSi(OEt)_3$ 3.9 g.; $Me_2C(OMe)_2$ 1.9 g.; $Me_2C(OEt)_2$ 1.4 g. No acetal resulted with Me_2SO_4 in C_6H_6, Et_2O, etc., with HCl as a catalyst or in MeOH with AcOH or picric acid as catalyst. *d*-Glucose (36 g.) with 25 g. Me_2SO_3 and 100 cc. 3% MeOH-HCl, warmed about 2 hrs., gave 19 g. α-Me and 2.8 g. β-Me *d*-glucoside. Starch (250 g.) gave 96% of α-Me glucoside. *d*-Galactose (36 g.) formed 28.3 g. of α-Me galactoside and only 0.1 g. of the β-Me deriv. *d*-Mannose gave only the α-Me deriv. Details are given for the prepn. of Me rhamnoside, α-Me and α-Et *l*-arabinoside and α-Et *d*-galactoside.

C. J. West

Reaction between multivalent alcohols or phenols and arsenic compounds, especially arsonoacetic acid. III. Bertil Englund. *J. prakt. Chem.* **129**, 1–23(1931); cf. *C. A.* **24**, 1841.—By use of the previously described method the following values for L_S have been detd. for the reactions of arsonoacetic acid (I) with $HO(CH_2)_nOH$ in AcOH at 25° (values of *n* and L_S given): 2, 0.205; 3, 0.060; 4, 0.052; 5, 0.0060; 6, 0.068; 7, 0.047; 8, 0.057; 9, 0.043; 10, 0.045. With As_2O_3 in BuOH contg. 5% H_2O values of *L* were detd. as follows: $MeCH(OH)CH_2OH$, 0.128; $HO(CH_2)_3OH$, 0.012; *meso*-$(MeCH(OH))_2$, 0.288; *dl*-deriv., 0.246; pinacol, 0.340; $HO(CH_2)_6OH$, 0.013; $HO(CH_2)_7OH$, 0; $HO(CH_2)_8OH$, 0.11. With I in AcOH the alicyclic diols gave the following values for L_S, the 2 figures being for the *cis*- and *trans*-forms: $C_6H_8(OH)_2$, 0.375, 0.034; $C_6H_{10}(OH)_2$, 0.420, 0.087; hydrindene-1,2-diol, 0.485, 0.050; tetrahydronaphthalene-1,2-diol, 0.475, 0.022. The diglycol esters of As_2O_3 are relatively weak acids; with excess of glycol there result complex triglycol derivs.; thus $HAs(C_2H_4O_2)_2$ has been isolated as salts of the acid. While the glycol deriv. of As_2O_3 and I show a double mol. wt. in $CHBr_3$, they are monomol. in Me_2CO. The pinacol deriv. (II) of I titrates as a monobasic acid in alc., using phenolphthalein as indicator; the other derivs. studied ($HOAsG_2$, $HO_2CCH_2AsG_2$ and $HOAsPn_2$, where G and Pn represent glycol and pinacol) are unstable and decomp. in EtOH. Data are given for the hydrolysis of II by H_2O; this is complete in about 1 hr. and in about half that time on the addn. of a small amt. of HCl; it is fairly resistant to alkali. The elec. cond. is also reported for 3 concns., 2 at 25° and 1 at 0°. The final value agrees well with that for As_2O_3. E. also discusses tensionless hetero rings.

C. J. West

Characterization of alkyl halides and organomagnesium halides. A. M. Schwartz and John R. Johnson. *J. Am. Chem. Soc.* **53**, 1063–8(1931).—The yields of RMgX from a series of alkyl halides are reported; these RMgX are characterized by transformation into the anilides of the corresponding acids with PhNCO; the cor. m. ps. for these anilides are given. The application of this method to certain branched-chain alcs. is limited by the fact that intramol. rearrangements may lead to anilides that do not correspond in structure to the original alc. Thus, 3-methylbutan-2-ol and 2,2-dimethylpropanol both give the anilide of dimethylethylacetic acid; allyl alc. gives the anilide of crotonic acid. An optically active halide, *d*-2-bromoöctane (in which the halogen is directly attached to the asym. C atom), led to a completely inactive anilide.

C. J. West

Partly abnormal reaction of β-substituted allyl bromides on organomagnesium bromides. Charles Prévost and Jean Daujat. *Bull. soc. chim.* [4], **47**, 588–94 (1930).—While with organomagnesium bromides the simple allyl bromide reacts thus: $RMgBr + CH_2:CHCH_2Br = MgBr_2 + RCH_2CH:CH_2$ (Kirrmann, *C. A.* **20**, 3443), β-substituted allyl bromides give rise to a desmotropism in this reaction: $RCH:CHCH_2Br + R'MgBr = MgBr_2 + RCH:CHCH_2R'$ or $MgBr_2 + RR'CHCH:CH_2$ (Prévost, *Ann. chim.* [10], **10**, 121). The 3 reactions (1) $EtMgBr + EtCH:CHCH_2Br$, (2) $PhMgBr + EtCH:CHCH_2Br$ and (3) $EtMgBr + PhCH:CHCH_2Br$ were studied in detail and the 5 theoretically expected *hydrocarbons*, $EtCH:CHCH_2Et$ (I), $Et_2CHCH:CH_2$ (II), $EtCH:CHCH_2Ph$ (III) $PhCH:CHCH_2Et$ (IV) and $PhEtCHCH:CH_2$ (V),

were isolated. For the prepn. of the β-substituted allyl bromides (Bouis, *C. A.* **22**, 213) the vinylcarbinols (Delaby, *Thesis*, 1923) were used. To the Mg reagent the allyl bromide in Et_2O is slowly added and the reaction is completed by several hrs. of refluxing. By using a slight excess of the Mg reagent immediately after decanting it from excess Mg, formation of brominated products as well as doubling of the allyl bromide is avoided. Although compds. I–V are not new, the consts. of II, IV and V were found to differ substantially from the literature. Reaction (1): I and II are sepd. by 4 distns. The total yield is above 80% and 3–4 times as much II as I is formed. II b. 85°, n_{22} 1.3966, d_{22} 0.6948, mol. refraction 33.94. Bromination yields the *dibromide* $Et_2CHCHBrCH_2Br$, b_{15} 93.5°, n_{24} 1.5006, d_{24} 1.5251, mol. refraction 49.81. KOEt forms *isoamylacetylene*, b. 87°, n_{22} 1.4023, d_{22} 0.7272, mol. refraction 32.24 (cf. Lespieau, *C. A.* **24**, 334). The *Ag salt* $Et_2CHC:CAg$ is very sol. in EtOH. Reaction (2): III and V are sepd. by 7 vacuum distns.; 2–3 times as much III is formed as V, and the total yield is excellent. V b_{12} 71°, b_{760} 191.5° (cor.), n_{21} 1.5030, d_{21} 0.8818, mol. refraction 48.95. Reaction (3): IV and V are sepd. by 3 vacuum distns. In a total yield of 75–85% about twice as much IV is present as V. IV b_9 87.5°, b_{14} 94°, b_{760} 217° (cor.), n_{17} 1.5318, n_{21} 1.5337, d_{17} 0.8924, d_{21} 0.8886, mol. refraction 50.7, 51.0. Some *bicinnamyl* was identified as a by-product. Data on I and III are also given. G. Toennies

Highly polymerized compounds. XLVII. Morphology of highly molecular substances. II. Polyoxymethylene precipitates from solutions. Hans W. Kohlschütter. *Ann.* **484**, 155–78(1930); cf. *C. A.* **25**, 15.—K. ppts. aq. $(CH_2O)x$ solns. (d_4^{19} 1.086) with H_2SO_4 and obtains 24 ppts., using various conditions of temp., amounts of H_2SO_4 and concns. of $(CH_2O)x$. Also, the effects of added substances (*e. g.*, MeOH) and of the substitution of HCl and H_3PO_4 for the H_2SO_4 were studied. The significance of the ppts. is discussed. C. J. West

Relation of the structure of ketones to their reactivity and affinity in acetal formation. II. Geo. J. Pfeiffer and Homer Adkins. *J. Am. Chem. Soc.* **53**, 1043–8 (1931); cf. *C. A.* **22**, 383.—HCO_2Et and Na react as follows: $3HCO_2Et + 4Na = 2CO + MeONa + 3EtONa$ (to be discussed in a later paper). The ratio of CO to HCO_2Et is independent of the amt. of $H(OEt)_3$ or of ketone acetal present in the mixt. subject to analysis; however, the ratio is dependent upon the amt. of EtOH and the amt. and kind of ketone present. A table is given showing the CO from HCO_2Et in the presence of various amts. of EtOH and ketones. The reaction of the various ketones with $HC(OEt)_3$ was carried out by mixing 0.1 mol. of ketone and 0.1 mol. $HC(OEt)_3$ in EtOH to give a total vol. of 49 ml., then adding 1 ml. of EtOH contg. 0.0136 g. HCl; after 50–60 hrs. 5 ml. aliquots were removed and decompd. with Na and EtONa; from the data the % acetal calcd. and equil. const., $K_E \times 10^2$, were detd. Me_2CO, 94.8, 334; MeCOEt, 90.1, 0.83; $MeCOCH_2CH_2Ph$, 89.1, 0.66; MeCOPh, 86.2, 0.39; Me neopentyl ketone, 84, 0.28; $(iso\text{-}Pr)_2CO$, 65.4, 0.034; *tert*-BuCOMe, 50.1, 0.0101; *tert*-BuCOEt, 36.2, 0.0033; Ph_2CO, 33.7, 0.0026; *tert*-$BuCOCHMe_2$, 25.8, 0.0012; $(tert\text{-}Bu)_2CO$, 17.2, 0.0004. These results show that any substitution in the Me groups of Me_2CO results in a lowering of the extent of the reaction. The extent of conversion is decreased only slightly by the substitution of a $PhCH_2$ group for 1 of the H of Me_2CO. The effect of the replacement of a Me by Ph is marked, while 2 Ph groups reduce the % conversion to acetal to about 33% of the value for Me_2CO. The b. p. and d. for the various compds. are given. C. J. West

Preparation of anhydrous pinacol. Harold S. King and W. W. Stewart. *Proc Trans. Nova Scotian Inst. Sci.* **17**, 262–7(1930).—The dehydration of pinacol hydrate was carried out by 3 methods: (1) To 118 g. pinacol, 108 g. water, and 700 cc. Et_2O cooled and shaken, 250 g. coarsely powd. CaC_2 was added. After standing, the mixt. was filtered and the filtrate distd. with a 3-ft. fractionating column. The fraction b. 170–4° weighed 106 g. and was pure anhyd. pinacol. In all, 90% of the hydrate was recovered. (2) Pure pinacol hydrate distd. on an oil bath under the same conditions gave only 75–80% of anhyd. pinacol. (3) Pinacol (118 g.), 108 g. water, and 200 cc C_6H_6 were distd. at 68° until all the water was removed through a condenser connected with an automatic separator from which the C_6H_6 siphoned back to the distg. flask. The C_6H_6 soln. was then heated on a metal bath to 170°. Anhyd. pinacol in 96% yield remained in the flask. The C_6H_6 dehydration method was used for the analysis of pinacol hydrate. It was found to contain 4.9% uncombined water when dried in the air for 24 hrs. Rachel Brown

Identification of fatty acids. I. Reinhard Seka and Robert H. Müller. *Monatsh.* **57**, 97–105(1931).—The reaction with $o\text{-}C_6H_4(NH_2)_2$ is proposed as a method of identifying fatty acids; the method seems to be applicable to acids up to C_{16}; the possible use with unsatd. acids is being studied. $o\text{-}C_6H_4(NH_2)_2$ and $PrCO_2H$, heated at 140–50°

for 8 hrs., give *2-propylbenzimidazole*, b_{15} 220°, m. 152–3°; *pentyl deriv.*, b_{15} 250°, m. 155–6°; *heptyl deriv.*, b_{15} 280°, m. 139–40; *nonyl deriv.*, b_{15} 280°, m. 114–5°; *hendecyl deriv.*, b_{15} 300°, m. 101–3°; *pentadecyl deriv.*, b_{15} 300°, m. 91–2°; *heptadecyl deriv.*, b_{15} 310°, m. 90–1°; *iso-Pr deriv.*, b_{15} 180°, m. 223–5°; *methylpentyl deriv.*, b_{15} 230°, m. 158–9°. C. J. West

Selective hydrogenation of unsaturated acids and their constitution. II. Isolinolinic acid of silk worm pupa. Yoshiyuki Inoue and Bunsuke Suzuki. *Proc. Imp. Acad.* (Japan) 7, 15–8(1931); cf. *C. A.* 24, 5283.—Oxidation of Me isolinolate with $KMnO_4$ in Me_2CO contg. $NaHCO_3$ gives $(CO_2H)_2$, caproic and azelaic acids, while the partially reduced acid gives pelargonic and azelaic acids. These results are the same as those obtained for linolic acid and so isolinolic acid is assigned the structure of octadeca-$\Delta^{9,10,12,13}$-dienoic acid; however, the 2 acids are not identical, for the Br deriv. of linolic acid m. 114°, while that of isolinolic acid is a liquid. Oxidation of the partially hydrogenated isolinolic acid in alk. soln. gives 2 dihydroxystearic acids, m. 130° and 100°, elaidic and stearic acids. Thus the 2 acids may be represented by the following:

$$\begin{array}{l} Me(CH_2)_4CH{:}CHCH_2CH \\ \qquad\qquad \| \\ HO_2C(CH_2)_7CH \end{array}$$
Linolic acid

$$\begin{array}{l} Me(CH_2)_4CH{:}CHCH_2CH \\ \qquad\qquad \| \\ HC(CH_2)_7CO_2H \end{array}$$
Isolinolic acid

These results are confirmed by measuring the velocity of hydrogenation; this runs in 2 stages and in both linolic acid is hydrogenated more rapidly. C. J. West

Partial hydrogenation of linolenic acid and its esters. T. P. Hilditch. *Chem. Umschau Fette, Oele, Wachse Harze* 37, 354–6(1930).—An answer to the Bauer and Ermann paper (*C. A.* 24, 5721) in which they state that no proof for a change in the ethylene bond during hydrogenation of linolenic acid was found and that the presence of suberic acid among the oxidation products by $KMnO_4$ may be due to secondary oxidation of the primary products. In answer it should be noted: (1) The oxidation by $KMnO_4$ in acetone causes no secondary oxidation of the di-CO_2H degradation products which are probably immediately pptd. and thus removed from the reaction; and oxidation of Me oleate, palmitoöleate, etc., produces only one di-CO_2H acid, azelaic acid. (2) Partially hydrogenated Me oleate yielded not only azelaic and suberic acids, but also sebacic acid, $C_8H_{16}(CO_2H)_2$, whose presence would be difficult of explanation when a secondary destructive oxidation is assumed. (3) While aq. $KMnO_4$ oxidation of oleic acid may produce azelaic, suberic, nonylic, octylic and oxalic acids, Lapworth and Mottram (*C. A.* 19, 2930) have shown that the aq. alk. $KMnO_4$ oxidation of the Na salt of 9,10-dihydroxystearic acid, the primary oxidation product of Na $\Delta^{9,10}$-oleate yields almost equal amts. of suberic, *n*-octylic and oxalic acids, the splitting taking place at the 8,9- and 10,11- and not at the 9,10-position. When oxidizing with $KMnO_4$ in acetone the primary formation of satd. di-HO acids does not occur and splitting is restricted to the 9,10-position. The observed differences are doubtless due to differences in the conditions under which hydrogenation occurred: B. and E. hydrogenated mainly at 20–120°, using 1.1–4.3% Ni for 12–30 hrs. while Hilditch and Vidyarthi hydrogenated mostly at 180–200°, using 0.3–0.6% Ni for 30-90 min.; they also observed that there is less change in the ethylene bond at 100–5° than at 180–200° and probably still less at B. and E.'s temp. of 20°. **Reply.** K. H. Bauer. *Ibid* 356.—Different hydrogenation conditions produce different results. The acetone $KMnO_4$ oxidation is more advantageous in this case than the O_3 oxidation. P. Escher

The parachor of some aliphatic acids of high molecular weight. G. B. Semeria and G. Ribotti-Lissone. *Gazz. chim. ital.* 60, 862–6(1930).—It is already known that with the Me esters of fumaric and maleic acids, of citraconic and mesaconic acids, of cinnamic and *allo*-cinnamic acids, etc., the parachor of the *cis*-form is smaller than that of the *trans*-form. In expts. with the free acids, it was found that the same fact is true of each pair of ethylenic acids with 18 and 22 C atoms, so that following the concept of Sugden and Whittaker (cf. *C. A.* 19, 3263), ordinary oleic acid (I) should have a *cis*-configuration and elaidic acid (II) and brassidic acid (III) *trans*-configurations. In the present paper, as with the results of Sugden (*loc. cit.*), the measurements of the parachors confirm the conclusions which can be deduced from other phys. consts. Thus, Mascarelli and Toschi (*C. A.* 10, 597), found by f.-p. measurements a *cis*-configuration for erucic acid (IV), a *trans*-configuration for III, and Keffler (cf. *C. A.* 24, 3702–3), from heats of combustion, considered I a *cis*-form and II a *trans*-acid. In view of this, the parachors of stearic acid (V) and of behenic acid (VI) were detd. to ascertain whether there is a relation between the parachors of these satd. acids and those of the corresponding ethylenic acids. The results show that the surface tension γ of the satd.

acids with 18 and 22 C atoms is nearly the same as that of the corresponding *trans*-ethylenic acids, while it is smaller than that of the *cis*-ethylenic acids. Moreover, the parachors of the satd. acids are greater than those of the corresponding unsatd. acids, while the parachors of the latter are the greater in the *cis*-forms. To complete the investigation the parachor of 2,3-oleic acid (VII) was detd., and since it was practically equal to that of II, the former has the *trans*-configuration as indicated by earlier expts. (cf. S., *C. A.* **19**, 1245). The differences in the parachors of each pair of ethylene isomers are small, but since these differences are systematic in both series and for different temps., they are not exptl. errors. Surface tensions γ were detd. by the method of max. boiling pressure with the Sugden app. (cf. *C.A.* **16**, 2627; **18**, 1771), and the parachors were calcd. by the formula $P = M\gamma^{1/4}/(D - d)$ of Sugden. The following data give d., γ and the parachor of the acids at 90° and at 95°, resp.: **I**, 0.84804, 0.84404, 27.94, 27.52, 765.07, 766.93; **II**, 0.84370, 0.83670, 26.56, 26.31, 760.44, 764.93; **VII**, 0.84843, 0.84039, 27.00, 26.89, 759.31, 763.70; **V**, 0.83602, 0.83102, 26.99, 26.42, 777.79, 778.87 (cf. 778 of Hunten and Maass, *C. A.* **23**, 1549); **IV**, 0.8357, 0.8327, 28.56, 27.77, 932.40, 938.91; **III**, 0.8324, 0.8294, 27.40, 27.28, 929.20, 934.36; **VI**, 0.8223, 0.8219, 27.77, 37.61, 950.07, 951.36. The exptl. values of the parachors are not compared with those calcd. theoretically, because the theoretical parachors are always different from the exptl. values when the no. of C atoms comprising the chain is very high. The results show that I and IV have *cis*-configurations, and II, VII and III have the *trans*-configurations.

C. C. DAVIS

Separation of glycerides. XVI–XVIII. BUNSUKE SUZUKI. *Proc. Imp. Acad.* (Japan) **7**, 9–11(1931); cf. *C. A.* **23**, 4928.—**XVI.** WITH YUTAKA MASUDA.—By use of the principle of fractional pptn. with $CaCl_2$ from EtOH and extn. of the petr. ether-insol. portion with various solvents the brominated oil from the bones of the common finbock (*Balaenoptera physalus*), the following bromides were isolated (only m. p. given): dilinoleno-zoömarin, 65°; clupanodono-linoleno-zoömarin, 132°; clupanodono-arachidono-olein, 95°; $C_{22}H_{42}O$-clupanodono-linolenin, 123°; arachidono-linoleno-olein, 145°; triarachidonin, 218°; the following are oils: linoleno-dizoömarin, stearo-linoleno-zoömarin, stearo-oleo-zoömarin, stearo-linoleno-zoömarin, oleo-dizoömarin, linoleo-diolein. **XVII.** WITH SHUZO OE AND UZO NISHIMOTO.—The skin of the finbock gave the following bromides: $C_{18}H_{37}O$-linoleno-stearidonin, 122°; $(C_{18}H_{37}O)_2$-stearidonin, 148°; cetoleo-linoleo-stearidonin, 172°; distearidono-zoömarin, 168° (decompn.); tristearidonin, 192° (decompn.); triolein and dieruco(?)-linolein. **XVIII.** WITH RYOZO YONEDA AND UZO NISHIMOTO.—The internal organs of the finbock gave the following bromides: clupanodono-$C_{22}H_{36}O$-linolenin, 105°; $C_{22}H_{38}O$(?)-linolenin, 98°; clupanodono-stearidono-zoömarin, 193°; diarachidono-gadolein, 220° (decompn.); linoleo-dizoömarin, oil.

C. J. WEST

The structure of synthetic mixed triglycerides. RAMKANTA BHATTACHARYA AND THOMAS PERCY HILDITCH. *Proc. Roy. Soc.* (London) **129A**, 468–76(1930).—Synthetic triglycerides were prepd. from various combinations of lauric, palmitic, and stearic acids with unsatd. acids (85% oleic and 15% linoleic). The curve of the molar percentage of the fully satd. glycerides plotted against the molar percentage of satd. acids in the synthetic mixt. gave corresponding values for a no. of natural animal fats (including butter and tallow) and for some vegetable pericarp fats, while vegetable fats have somewhat less fully satd. glycerides than the synthetic fats for a given ratio of satd. to unsatd. acids. Vegetable seed fats are almost invariably assembled on different principles, the glyceride structure being detd. by a tendency to even distribution. In this case, fully satd. glycerides rarely appear in appreciable quantity until the molar proportion of satd. acids in the mixed fatty acids reaches 60%.

H. J. DEUEL, JR.

Origin of stereochemistry. EMANUELE PATERNÒ. *Gazz. chim. ital.* **60**, 910–1 (1930).—Certain misstatements in a recent book by Oddo ("Trattato di chimica organica") are discussed.

C. C. DAVIS

Stereochemistry of organic compounds. II. Spatial rearrangement of the a oms in the pentaerythritol molecule. LUDWIG ORTHNER AND GERTRUD FREYSS. *Ann.* **484**, 131–54(1930); cf. *C. A.* **22**, 81.—Details are given for the prepn. of the mono-(I) and diacetone (II) derivs. of pentaerythritol (III) (cf. *C. A.* **22**, 1327). I and Na in $C_6H_4Me_2$, heated 3 hrs., then treated with MeI and again heated 2 hrs., give 43% of the *mono-Me deriv.* (IV), b_{12} 129–30°; Ag_2O and MeI with I give 70% of III; *p*-nitrobenzoate, m. 90°. IV with NaOH in 70% MeOH gives 60% of the Me deriv. of III, m. 72°. I in Me_2SO_4 and 5% KOH give a mixt. of the *di-Me deriv.* (V) of III, b_{12} 139°, m. 32° (*dibenzoate*, m. 70°), and the *tri-Me deriv.*, b_{12} 103–4° (*p*-nitrobenzoate, m. 53–4°). I and BzCl in C_5H_5N give the *di-Bz deriv.*, m. 110°, hydrolyzed by HCl in Me_2CO to the di-Bz deriv. (VI) of III, m. 75°; further action of BzCl gives the tetra-Bz deriv. of

III, m. 94°, identical with that obtained from III and BzCl. I, Ac_2O and AcONa in $CHCl_3$, heated 1 hr., give 90% of the *di-Ac deriv.*, m. 48–9°; hydrolysis at room temp. gives 25% of the *di-Ac deriv.* of III, $b_{0.3}$ 159°; on standing, the tetra-Ac deriv. (VII) and III sep. Cond. measurements are reported for I, V and VI in H_2O and H_3BO_3. Dipole detns. are given for VII and II; μ was found to be 2.18 ± 0.03 and 2.26 ± 0.07, each × 10^{-18} c. g. s. The spatial structure of III is discussed and illustrated by diagrams. C. J. WEST

Preparation of 1,3,9- and 3,7,9-trimethyluric acid. HEINRICH BILTZ AND HEINZ PARDON. *Ber.* **63B**, 2876–80(1930).—*8-Methoxytheobromine* (I), from the 8-Cl compd. with Na in MeOH, m. 282°, at once resolidifying (probably rearranging into 3,7,9-trimethyluric acid (II)) and then m. 370–80°. Heated 0.5 hr. at 290° (not higher), 10 g. I gives 5 g. II, m. 373–5° (decompn.), readily methylated by alk. Me_2SO_4 to tetramethyluric acid, m. 228°. 1,3,9-Trimethyluric acid (III) is prepd. by heating K 1,3-dimethylurate with *p*-$MeC_6H_4SO_3Me$ in *o*-$C_6H_4Cl_2$ at 150°; the crude product is purified by removing the more strongly acid 1,3-di-Me compd. by boiling up in dil. NH_4OH or by just dissolving in 23% KOH and pptg. the III with CO_2; yield, 3.2 g. from 10 g. of the di-Me acid. The III decomps. 340°, as does that prepd. from 9-methyl-*ps*-uric acid (Strufe gives 347°). An attempt was made to prep. III from 8-chlorotheophylline (obtained in 8 g. yield in needles, m. 304° (decompn.), from 10 g. theophylline with $KClO_4$ in HCl), but the Cl compd. was unchanged by KOH or NaOH in boiling MeOH or by KOMe or NaOMe at 140° in sealed tubes. C. A. R.

Preparation and properties of crystallized alkali salts of *l*-cystine. GERRIT TOENNIES AND THEODORE F. LAVINE. *J. Biol. Chem.* **90**, 203–13(1931).—The Li, Na and K salts of *l*-cystine have been prepd. by pptn. of alc. alk. cystine solns. with MeCN. A method of recrystn. was not found and repptn. under the conditions of prepn. did not improve the purity or cryst. form. However, analysis indicated that the original prepns. were fairly pure. The salts are very sol. in water and the aq. solns. are practically stable for several days, a noteworthy fact in view of the known instability of cystine solns. when boiled with excess alkali. $[\alpha]_D$, calcd. for cystine at 29°, for the Li, Na and K salts, resp., in water is: —94.4°, —90.9° and —91.1°. A. P. LOTHROP

Condensation between aliphatic esters and ketones. S. G. POWELL AND KEITH M. SEYMOUR. *J. Am. Chem. Soc.* **53**, 1049–51(1931).—With the Claisen condensation, AcOEt and MeCOEt or $EtCO_2Et$ and Me_2CO give 11 and 15%, resp., of $(MeCOCH_2)_2$. $EtCO_2Et$ and MeCOPr or $PrCO_2Et$ and MeCOEt give 9 and — % of $(EtCOCH_2)_2$. AcOEt and $MeCOCHMe_2$ or iso-$PrCO_2Et$ and Me_2CO give 14 and 6%, resp., of 2-methyl-3,5-hexanedione. Modifications of proportions and conditions did not change the course of the reaction in the cases studied. C. J. WEST

Sugar oxidation and destruction. X. Formation of methylglyoxal from sugars and from related substances under the influence of hydrogen peroxide. K. BERNHAUER AND H. TSCHINKEL. *Biochem. Z.* **230**, 484–92(1931); cf. *C. A.* **24**, 4268.—Under the influence of H_2O_2 in the presence of $FeSO_4$ in acid soln., MeCOCHO is formed from various sugars and especially from γ-Me glucoside. In the absence of $FeSO_4$, however, acids, particularly HCO_2H, are produced instead. **XI. Formation of phenol-like compounds in the decomposition of sugar.** K. BERNHAUER AND J. NEPP. *Ibid* 493–500.—Phenol-like substances are formed in very minute amts. and only under special conditions from carbohydrates. KCO_2H when used in making the phenol fusion mixt. leads to the formation of *o*- and particularly of *m*-$HOC_6H_4CO_2H$ from phenol. **XII. The formation of higher fatty acids in the destruction of sugar.** *Ibid* 501–4.—There is no evidence found that higher fatty acids result when sugars are acted upon by concd. alkalies. S. MORGULIS

Glucuronic acid fermentation. II. TEIZO TAKAHASHI AND TOSHINOBU ASAI. *Proc. Imp. Acad.* (Japan) **7**, 5–8(1931).—See *C. A.* **24**, 4319. C. J. WEST

Course of addition of sodium enol alkylmalonic and sodium enol alkylcyanoacetic esters to unsaturated esters. ARTHUR MICHAEL AND JOHN ROSS. *J. Am. Chem. Soc.* **53**, 1150–72(1931); cf. *C. A.* **25**, 82.—The course of the addn. of a deriv. of the Na enol malonic ester type to an α,β-unsatd. ester proceeds according to the law of chem. neutralization. That addn. product is therefore formed in which the positive energy of the Na atom is best neutralized, since the max. energy degradation is thus realized. In the addn. of Na enol alkylmalonic esters to fumaric ester, the alkyl group migrates so that the addendum parts are alkyl and $-C(CO_2Et):C(ONa)OEt$; in the addn. of Na enol alkylcyanoacetic esters to crotonic ester, the addendum parts are similarly alkyl and $-C(CN):C(ONa)OEt$. In the addn. to crotonic ester, the yield of addn. product was greater in the case of Na enol methylcyanoacetic ester (50%) than with Na enol ethylcyanoacetic ester (33%). However, the yield of addn. product is detd.

by several complex factors so that it is not possible from these expts. to make any statement regarding the relative ease of migration of the Me and Et groups in these addn. reactions. The max. chem. neutralization of the Na is realized by the Na remaining attached to the carbonyl O atom in the malonic or cyanoacetic groups. The Na atom, however, becomes better neutralized than it was in the addendum by the spatial negative influence of the acquired CO_2Et group. Esters of the type $CHX(CO_2Et)CHY\text{-}CZ(CO_2Et)_2$ (where X = R or H, Y = R, H or CO_2Et and Z = R or H, also R is an alkyl or aryl radical), apparently form enolic Na derivs. contg. the group -CH:C(ONa)OEt, but these immediately decomp. to form ethylenic α,β-esters and Na alkylmalonic esters. The retrogression of the free ester (A) by Na is probably due to the formation of such an enolic Na deriv. It would follow from this relationship that the Na atom involved in the addn. reactions specified above cannot migrate during the addn. process. However, if the single CO_2Et group of (A) can form an enolate, an amt. of Na corresponding to the relative acidity of the 2 enolic forms of ester (A) (Z = H), would migrate to the single CO_2Et group according to the partition principle, and spontaneous retrogression would lead to the reformation of a further quantity of the Na enol deriv. Thus, by this process, in agreement with the partition principle, an apparent balanced state would be achieved between the 2 possible stable Na derivs. It has not been found possible to obtain addn. to the γ-C atom of a β,γ-unsatd. ethylenic ester or nitrile. Addn. occurs in the case of allyl cyanide and styrylacetic ester at the α- and β-C atoms with migration of an α-H atom. $CH_2(CO_2Et)_2$ and $(CHCO_2Et)_2$ with a little EtONa give 90% of the Et ester, b_5 187°, of *propane-α,β,γ,γ-tetracarboxylic acid*, m. 153°. The ester (22 g.) in an Et_2O suspension of anhyd. EtONa, methylated with 10 g. MeI, gives 21 g. of the *Et ester*, b_3 180°, of *butane-α,β,γ,γ-tetracarboxylic acid*, m. 170°. *Pentane-β,γ,δ,δ-tetracarboxylic acid*, m. 166°, results from the sapon. of the ester obtained from the butane deriv. and MeI with EtONa at 0°. The propane deriv. and EtI with EtONa give the *Et deriv.*, b_3 180°, of *pentane-α,β,γ,γ-tetracarboxylic acid*, m. 177°. *Pentane-α,α,β,γ-tetracarboxylic acid* m. 179° (decompn.). *Hexane-β,β,γ,δ-tetracarboxylic acid*, m. 170°, is formed from the Et ester of the last-named acid, MeI and EtONa at 0°. Addn. of MeC(CN):C(ONa)OEt to $MeCH{:}CHCO_2Et$ gives 50% of the *Et ester*, b_3 145-8°, of *α,β-dimethyl-γ-cyanoglutaric acid*, which could not be crystd.; the corresponding *γ-carboxy deriv.* m. 142° and is not identical with the acid obtained from tiglic acid. β,γ-Dimethyl-γ-cyanoglutaric acid m. 152°. EtC(CN):C(ONa)OEt and $MeCH{:}CHCO_2Et$ give 33% of the *Et ester*, b_3 153°, of *γ-cyano-α-ethyl-β-methylglutaric acid*, m. 147°; this gives with HCl a mixt. of *α-ethyl-β-methylglutarimides*, m. 92° and 102°; hydrolysis of the imide, m. 92°, gives *cis-α-ethyl-β-methyglutaric acid*, m. 88°. Complete hydrolysis of the above ester gives *α-ethyl-β-methyl-γ-carboxyglutaric acid*, m. 147°. $MeC{:}CEtCO_2H$ and NCCH:C(ONa)OEt give 60% of the *Et ester*, b_4 152°, of *α-ethyl-β-methyl-γ-cyanoglutaric acid*, m. 132°; complete hydrolysis gives the *γ-carboxy deriv.*, m. 141°. Ethylation of γ-cyano-β-methylglutaric ester gives the *Et ester*, b_4 152°, of *γ-ethyl-β-methyl-γ-cyanoglutaric acid*, m. 139°; γ-ethyl-β-methyl-γ-carboxyglutaric acid could not be crystd. $CH_2{:}CHCH_2CN$ and NCCH:C(ONa)OEt give 90% of *β-methyl-γ-carbethoxyglutaronitrile*, b_3 160°; MeC(CN):C(ONa)OEt gives *α,β-dimethyl-γ-carbethoxyglutaronitrile*, b_3 152°. $PhCH{:}CHCH_2CO_2Et$ and $CNCH_2\text{-}CO_2Et$ with EtONa give *Et β-benzyl-γ-cyanoglutarate*, b_3 193°; hydrolysis gives β-benzyl-γ-carboxyglutaric acid, m. 158°; the Na deriv. of the ester and MeI give *Et γ-methyl-β-benzyl-γ-cyanoglutarate*, b_3 194°; alk. hydrolysis gives *γ-methyl-β-benzyl-γ-carboxyglutaric acid*, m. 177° (decompn.), giving *α-methyl-β-benzylglutaric acid*, m. 139°. $PhCH{:}CHCH_2CO_2Et$ and $MeCH(CO_2Et)_2$ with EtONa give the *Et ester*, b_3 197°, of *α-methyl-β-benzyl-γ-carboxyglutaric acid*, which exists in 2 forms, m. 197° and 118°; heating above their m. p. gives 2 α-methyl-β-benzylglutaric acids, m. 139° (cf. above) and 97°. PhMeCHCHO and $CH_2(CO_2H)_2$ in EtOH give a mixt. of the *Et esters*, b_{10} 156° and b_{10} 175–82°, of *γ-methyl-γ-phenylbutenoic acid* (I), did not crystallize, and γ-methyl-γ-phenyl-α-carboxybutenoic acid, m. 151°. I and $NCCH_2CO_2Et$ with EtONa give *Et γ-methyl-γ-phenyl-α-cyano-β-aceticbutyrate*, b_3 198°; alk. hydrolysis gives *γ-methyl-γ-phenyl-α-carboxy-β-aceticbutyric acid*, m. 162° (decompn.), giving *γ-methyl-γ-phenyl-β-aceticbutyric acid*, m. 88°. Iron nitrosyls and their behavior on oxidation. HANS REIHLEN, E. ELBEN AND J. EVERET. *Ann.* **485**, 43–52(1931).—$(NO)_2Fe(S_2COEt)_2$ (I) (Manchot and Davidson, *C. A.* **23**, 4417) results in 91% yield (on the basis of the Fe) or 95% yield (on the basis of NO) from 10 g. $FeSO_4$ in 70 cc. H_2O and 12–14 g. K xanthate in 30 cc. H_2O to which are added 50 cc. CS_2 or $CHCl_3$ and the whole satd. with NO (av. absorption, 1500 ± 50 cc.); expts. at 0–40°, addn. of KOH or AcONa, or variation of the ratio of K xanthate to Fe from 0.5 to 4, always gave the same result. With EtOCOSK there results 35% of *dinitroso ferrous Et thiocarbonate* (II), $(ON)_2FeSCO_2Et$, brown-black, much less stable than I and reacts much more quickly with acids and alkalies. I, on heating at 60–80°, gives a N-free sublimate, *S,O-di-Et thiocarbonate*, b_{10} 76°, n_D^{19} 1.5375. The behavior of I and II on autoxidation is shown in curves. I in C_6H_6, on shaking with 1 atom of O, gives a compd. contg. about 30% of $(NO)O:NOFe(S_2COEt)_2$.

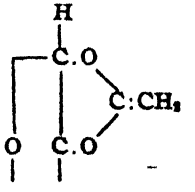
C. J. WEST



Carbohydrates. X. Further 1,2-derivatives of glucose. PERCY BRIGL AND RICHARD SCHINLE. *Ber.* **63B**, 2884–7(1930); cf. *C. A.* **24**, 4509.—An entirely different and materially smoother method of prepg. 2-methylglucose (I) (*C. A.* **24**, 74) is described. Tetrabenzoylglucose di-Et mercaptal reacts with extraordinary ease with MeI and Ag_2O, yielding half its wt. of *tetrabenzoyl-2-methylglucose di-Et mercaptal*, 88–9°, $[\alpha]_D^{18}$ 64.33–64.57° (Me_2CO), sapond. by NaOEt to 2-methylglucose di-Et mercaptal, m. 178°, identical with that obtained from glucose mercaptal with MeI and yielding with aq. $HgCl_2$ I, m. 158°, shows slight mutarotation in H_2O, $[\alpha]_D$ changing from 56.6–59.2° in 0.5° hr. to 64.9–65.6° in 48 hrs.; phenylhydrazone, m. 177°, $[\alpha]_D^{19}$ —13.3° (C_5H_5N) (heating with more $PhNHNH_2$ gives the Me-free glucosazone, m. 205°).

C. A. R.

Sugar anhydrides. II. Action of trimethylamine on acetobromo-*l*-rhamnose. FRITZ MICHEEL AND HERTHA MICHEEL. *Ber.* **63B**, 2862–6(1930); cf. *C. A.* **23**, 3669.—It was shown recently (*C. A.* **24**, 2727) that acetohalogenosugars whose substituents on the 1- and 2-C atoms are in the *cis*-position can form quaternary NH_4 salts with NMe_3 while the *trans*-derivs. do not. The acetohalogen derivs. of *d*-mannose and *l*-rhamnose form no quaternary derivs., but while the mannose compd. can be recovered almost unchanged even after long-continued action, acetobromorhamnose undergoes another reaction. In abs. alc. after a sufficiently long time almost all the Br is split off and seps. as $NMe_3.HBr$. Tetraacetylethylrhamnoside is not formed, however; there are obtained chiefly a diacetylrhamnose anhydride (I), 2,3,4-triacetyl-β-rhamnose (II) and an unsatd. non-cryst. compd. The yields of these products vary considerably and it has not yet been possible to establish the conditions necessary for obtaining I, especially, in reproducible yields. I, to which the accompanying structure is assigned provisionally, is probably formed by splitting off of Br with the Ac group on C atom 4 as AcBr which reacts with the alc. to form AcOEt and HBr, the latter sepg. as $NMe_3.HBr$. By using C_6H_6 instead of EtOH as solvent, it is possible to isolate the very unstable $AcBr.NMe_3$. I reduces Fehling soln. only very little after sapon. of the Ac groups but powerfully after boiling with acids, and it is stable toward Br in AcOH and

(I)

(III)

$KMnO_4$ in Me_2CO. It has not been possible to obtain the corresponding carbohydrate in pure form, however. Cautious alk. sapon. gives sirups which after long standing in the air reduce Fehling soln. and deposit small quantities of *l*-rhamnose hydrate, while a dil. soln. of HCl in MeOH produces a change in rotation from —24.1° to —9.8° but yields no cryst. rhamnoside acetate. The simultaneous formation of II renders the isolation of I difficult. The mother liquors from I and II give a sirup which reacts

strongly with Br and $KMnO_4$; it may be a compd. of the glucal type or a ketene-acetal-like product (III) derived from the tautomeric form of acetobromorhamnose. The easy elimination of AcBr from acetobromorhamnose indicates that the mobile 6-membered pyran ring is fixed in a position in which the Br atom is close in space to an Ac group; if no Walden inversion occurs at C atom 1 in the ring closure, this can result only in the formation of *(α1,4)(β1,5)-rhamnosan 2,3-diacetate* (I), since the Br is in the *trans*-position to the Ac groups on C atoms 2 and 3. The acetohalogenomannoses, which under the same conditions are stable toward NMe_3, have an $AcOCH_2$ group instead of the end Me group of the rhamnose. This end $AcOCH_2$ group probably favors a form of the pyran ring in which the Br and Ac groups are not close to each other. I (0.9 g. from 2 g. acetobromo-*l*-rhamnose), m. 124–5°, $[\alpha]_D^{20}$ —21° ($CHCl_3$). C. A. R.

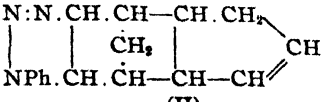
Nitrogen-containing sugars. II. Synthesis of peptide-like compounds from amino sugars and amino acids. I. Glucosamine as the component. Alfred Bertho, Fritz Hölder, Werner Meiser and Franz Hüther. *Ann.* **485**, 127–51(1931); cf. *C. A.* **24**, 3761.—Glucosamine-HCl (8.64 g.) in 400 cc. 0.2 *N* NaOH, treated during 20 min. with 4.52 g. $ClCH_2COCl$ with cooling, give about 5% of *chloroacetyl-N-glucosamine*, m. 168–9°, $[\alpha]_D^{24}$ 24.8° (MeOH); Fehling soln. is easily reduced. The α-bromopropionyl deriv. (I) m. 200–1°, $[\alpha]_D^{20}$ 52.5° (H_2O) after 17 min., changing to a const. value of 35.2° in 18 hrs.; crystn. of this prepn. tends to increase the component with the higher rotation, since the const. value for the product crystd. once is 23.78°. The α-bromoisocaproyl deriv. (II), m. 178° (decompn.), also shows mutarotation, the value of $[\alpha]_D^{22}$ changing from 39.67° (H_2O) after 30 min. to 24.70° after 24 hrs. I and MeOH-NH_3, on standing 3 months at 0°, give a mixt. of dehydroalanyl-*N*-glucosamine anhydride (III), m. 272° (decompn.), and *alanyl-N-anhydroglucosamine anhydride* (IV), m. 199°. Concd. NH_4OH at 0° gives principally III but a small amt. of IV. MeOH-NH_3 at 100° gives almost completely IV. III reduces Fehling soln. only after long heating; it does not liberate N in the Van Slyke app.; $[\alpha]_D^{23}$ —38.0° (H_2O); it is unchanged after heating with MeOH-NH_3 3 hrs. at 70–5° and 3 hrs. at 100°. IV likewise reduces Fehling soln. only after long heating and in the Van Slyke app. liberates 42% of its N after shaking 7 hrs. The *tetra-Bz deriv.* of I m. 189°, $[\alpha]_D^{18}$ 86.7° ($CHCl_3$), does not reduce Fehling soln.; a small amt. of *tetrabenzoyl-(α-hydroxypropionyl)-N-glucosamine* is also formed, m. 238°, $[\alpha]_D^{25}$ 15.87° ($CHCl_3$). II also yields a *tetra-Bz deriv.*, m. 189°, $[\alpha]_D^{18}$ 103.1° ($CHCl_3$). *Hippuryl-N-glucosamine*, m. 200° (decompn.); it reduces Fehling soln. but does not react with MeI; $[\alpha]_D^{21}$ 43.47° (C_5H_5N). *p*-Bromohippurazide gives the *compd.* $C_{24}H_{25}O_9N_5Br_2$, m. 214°. Benzoylalanine azide gives *benzoylalanyl-N-glucosamine*, m. 222° (decompn.), $[\alpha]_D^{22}$ 59° (H_2O). C. J. West

Acetylmonoses. VI. The ring structure of the mannose pentaacetates. P. A. Levene and R. Stuart Tipson. *J. Biol. Chem.* **90**, 89–98(1931); cf. *C. A.* **18**, 76, 1274; **21**, 1969, 3184.—Hudson (*C. A.* **24**, 2726) has recently attributed different ring structures to *α-d-* and *β-d*-mannose, and if this assumption is correct the α- and β-pentaacetates should also possess different ring structures. L. and T. find on examg. the 2 forms that this is not the case. Fifty g. of β-mannose pentaacetate treated with AcOH and HBr gave 32 g. of 1-bromotetraacetyl-*d*-mannose (I), m. 53–4°, $[\alpha]_D^{26}$ 123.2° (in $CHCl_3$), Treatment of I (25 g.) with Zn dust and AcOH gave 12 g. triacetylglucal, m. 54–5°, $[\alpha]_D^{25}$ —16.3° (in abs. EtOH). The action of AgOAc on 17 g. of I gave 15 g. of a compd. m. 74, $[\alpha]_D^{26}$ +56.6° (in $CHCl_3$), which was found to be identical with *α-d*-mannose pentaacetate. Dry NaOMe acted on I to give the peculiar tetraacetylmethylmannoside of Freudenberg (*C. A.* **24**, 4509), m. 104–5°, $[\alpha]_D^{27}$ —22.6° (in $CHCl_3$), while treatment with Ag_2CO_3 gave 2,3,4,6-tetraacetylmannose (II), m. 93°, $[\alpha]_D^{27}$ +26.3° (in $CHCl_3$). II strongly reduced hot Fehling soln., and on acetylation gave β-mannose pentaacetate, m. 117°, $[\alpha]_D^{21}$ —24.1° (in $CHCl_3$). It thus appears that the 2 pentaacetates are the α- and β-forms of the same ring isomer. H. W. Leahy

The preparation and melting point of anhydrous β-maltose. J. Gillis. *Natuurw. Tijdschr.* **12**, 193–9(1930).—β-Maltose hydrate is dehydrated *in vacuo* below 100°, contrary to the results of deBruyn and van Leent (*Rec. trav. chim.* **13**, 218(1894)). The m.-p. curves show that the anhyd. substance m. 108°, while the hydrated form m. 102–3°. The product obtained by deBruyn was probably a supercooled mixt. of about 56% of β- and 46% of α-maltose. R. C. Hockett

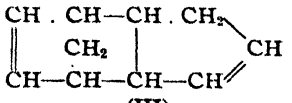
Autohydrolysis of diastatic dextrins. Jean Effront. *Compt. rend.* **192**, 198–201 (1931).—Reducing dextrins are formed during one of the primary phases of the process

of starch saccharification. The maltose encountered in the course of the dextrin disappearance results from the breaking down of these reducing dextrins. In the process of purification by solvents or dialysis autohydrolysis plays a dominant part, while the phenomenon of polymerization also occurs. The final products are, therefore, always impure, a condition similar to the one encountered in the study of the decompn. of starch. B. S. LEVINE



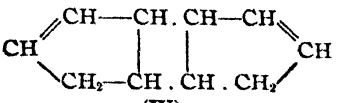
The supposed depolymerization of glycogen. ENDRE BERNER. *Ber.* **63B**, 2760–4 (1930).—B. showed recently (*C. A.* **24**, 5730) that the supposed depolymerization of inulin described by Vogel and Pictet and by Pringsheim, Reilly and Donovan is explained by the fact that inulin eagerly adsorbs such substances as alc., glycerol, glycol and $AcNH_2$ and thereby becomes easily sol. in H_2O; analysis of the supposed depolymerizates showed that the adsorbed substances, together with the pure inulin, corresponded quantitatively to the relatively large observed f.-p. depressions. B. now shows that this is also true of Reilly, Pringsheim and Donovan's glycogen prepns. (*C. A.* **24**, 3996). When well-dried glycogen is dissolved in anhyd. solvents, like fused $AcNH_2$, $HCONH_2$ or glycol and pptd. with abs. alc., it adsorbs large quantities of these substances, the adsorption being greatest when the H_2O is removed as completely as possible, *e. g.*, if the glycogen soln. is heated some time *in vacuo* before the pptn. The quantity of $AcNH_2$ adsorbed also decreases with increasing quantities of alc. used for pptn. The ppts. give up their alc. only slowly *in vacuo* over $CaCl_2$ but in the air they lose it more rapidly because the hygroscopic substances take up H_2O and the adsorption of alc. is thereby diminished. This explains why the H_2O must be removed before good adsorption will take place. A prepn. obtained by dissolving glycogen in $HCONH_2$ at room temp., pptg. and washing with abs. alc. and drying 2 days *in vacuo* over $CaCl_2$ gave an apparent mol. wt. of 342 in H_2O but contained 9.16% alc. and 0.25% $HCONH_2$; after standing several hrs. in the air the apparent mol. wt. was 610 and a couple of hrs. later 960; the prepn. now contained only 2% alc. A prepn. similarly obtained from a soln. of glycogen in $HCONH_2$ which had been heated 1 hr. *in vacuo* at 90–5° gave an apparent mol. wt. of 255 increasing, after 2 days in the air, to 317; it contained 4.13% alc. and 6.27% $HCONH_2$, and an aq. soln. of the same quantities of glycogen, alc. and $HCONH_2$ gave an apparent mol. wt. of 364. A prepn. similarly obtained from glycol gave in H_2O the same opalescence as true glycogen solns. and was colored by I in the same way. The glycogen was prepd. from calves' livers and after careful purification (finally by electro-dialysis) formed a friable powder of the compn. $C_6H_{10}O_5$ (ash less than 0.02%), $[\alpha]_D^{20}$ 194.5° in H_2O. The better it was dried, the less did it depress the f. p. of H_2O, pointing to the presence of alc., which, like H_2O, is removed with great difficulty; only heating at 100–10° *in vacuo* gives a product of the compn. $C_6H_{10}O_5$, which may account for the large depressions found by R., P. and D., who dried their glycogen only at 80°. C. A. R.

Cyclopropene series. I. Diphenylcyclopropenedicarboxylic acid. S. F. DARLING AND E. W. SPANAGEL. *J. Am. Chem. Soc.* **53**, 1117–20(1931).—*Di-Me α-bromo-β,γ-diphenyl-γ-nitroethylmalonate*, m. 117–8°, with AcOK in MeOH gives *di-Me 1,2-diphenyl-2-nitro-3,3-cyclopropanedicarboxylate*, m. 129°; refluxing with MeONa splits off $NaNO_2$, giving the *di-Me ester*, m. 140–2°, of *1,2-diphenyl-3,3-cyclopropenedicarboxylic acid*, m. 190° (evolution of CO_2); oxidation with $KMnO_4$ gives CH_2Bz_2; Br and the ester give *di-Me 1,2-dibromo-1,2-diphenyl-3,3-cyclopropanedicarboxylate*, m. 194–5°. Melting the acid gives the *lactone*, $C_{16}H_{12}O_2$, m. 149–51°, hydrolyzed to *1,2-diphenyl-2-hydroxy-3-cyclopropanecarboxylic acid*, m. 146–8°; this is not oxidized by O_2. C. J. WEST



Polymerization and pyrogenic decomposition of phenylacetic anhydride. I. Cyclobutane-α-dione. P. KALNINS. *Acta Univ. Latviensis Kim. Fakultat. Serija* **1**, No. 13–7, 455–67, 468(1930)(in German).—In the prepn and fractionation of $(PhCH_2CO)_2O$ there is formed by decompn., a red substance, probably diphenylcyclobutane-α-dione, while $PhCH_2CO_2H$ distils over. This results by the unsym. polymerization of the anhydride, with the splitting off of 2 mols. $PhCH_2CO_2H$. The intermediate product of the polymerization is colorless and easily changed into the red diketone. The latter with EtONa undergoes a mol. rearrangement, similar to the benzilic acid rearrangement, the product being $PhCH_2CHPhCOCO_2H$. This is 1 of the few examples of unsym. polymerization, most of the polymerizations yielding sym. compds. The study is being extended to other anhydrides. C. J. WEST

Polymerization of cyclic hydrocarbons. I. Polymeric forms of cyclopentadiene. KURT ALDER AND GERHARD STEIN (WITH HUGO FINZENHAGEN). *Ann.* **485**, 223–46 (1931).—Dicyclopentadiene (I) and PhN_3 give the *addn. compd.* (II), m. 130–1°, decompd. by mineral acids with liberation of N. The dihydro deriv. of I, m. 50–1°, does



not react with PhN_3, thus indicating structure III as opposed to IV. Oxidation of the dihydro deriv. of I with $KMnO_4$ in Me_2CO gives 3,6-endomethylenehexahydrohomophthalic acid, m. 137°, and cyclopentane-1,3-dicarboxylic acid, isolated as the anhydride, m. 163°. Decompn. of the bisnitrosochloride of I gives the unsatd. ketone (V), m. 216°; dihydro deriv., m. 109–10° (*semicarbazone*, m. 229° (decompn.)); oxidation yields *cis-pentalan-1,3-dicarboxylic acid* (VI), m. 230°. Excess BzO_2H and I give the dioxide, m. 189°; the action of 1 mol. BzO_2H upon I in $CHCl_3$ at —12° gives a mixt. of *monoxides* (VII and VIII); while these cannot be sepd. by crystn., VII adds PhN_3, giving a *triazole* (IX), m. 149°. From the petr. ether mother liquor VIII, b_{15} 100–10°, m. 79–80°, is isolated; catalytic reduction of VIII gives a *dihydro deriv.*, m. 118–9°. Tricyclopentadiene adds PhN_3, giving the compd. $C_{21}H_{23}N_3$, m. 199–200° (decompn.).

Graduated addition capacity of unsaturated ring systems. Kurt Alder and Gerhard Stein. *Ann.* **485**, 211–22(1931).—The peculiar behavior of dicyclopentadiene toward PhN_3 lead to the study of other compds. of this type. Santene and PhN_3 give an *addn. compd.* (I), m. 86°. Δ^4-3,6-Endomethylenetetrahydro-*o*-phthalic anhydride gives the *compd.* $C_{15}H_{13}O_3N_3$, decomps. 225°. Dihydromonocyclopentadienequinone and PhN_3 give the *compd.* II, m. 194°; $PhCH_2N_3$ gives the *compd.* $C_{18}H_{19}O_2N_3$, m. 141°; N_2CHCO_2Et gives the *compd.* $C_{16}H_{18}O_4N_2$, m. 177°. Dihydromonocyclohexadiene- and -butadienequinone do not react with PhN_3. Biscyclopentadienequinone and PhN_3 give the *compd.* III, darkens above 200° and decomps. 258°; the corresponding hexadiene and butadiene derivs. did not react. 3,6-Endoxo-Δ^4-tetrahydro-*o*-phthalic anhydride and PhN_3 give the compd. $C_{14}H_{11}O_4N_3$, decomps. 200°. *N,N'*-Dicarbethoxy-3,6-endomethylenetetrahydropyridazine and PhN_3 give the compd. $C_{17}H_{21}O_4N_5$, m. 126°.

Induction of the reaction between chlorine and benzene and ethylene. T. D. STEWART AND M. H. HANSON. *J. Am. Chem. Soc.* **53**, 1121–8(1931); cf. *C. A.* **24**, 3984.—$C_6H_6Cl_6$, together with substitution products, is formed when C_2H_4 is passed into a C_6H_6 soln. of Cl in the dark. A mixt. of the various stereoisomers is obtained, with the α-form (m. 157°) predominating. The molar ratio of total Cl reacting to C_2H_4 reacting varies from 2 to 11 in the present expts. and is greater the lower the partial pressure of C_2H_4. This is explained on the basis of chain mechanisms for both the C_2H_4-Cl and C_6H_6-Cl reactions, the latter being induced by and acting as an inhibitor of the former. In homogeneous soln. the above ratio, with Cl in large excess, is approx. 2. A higher proportion of the Cl is used in substitution than in the heterogeneous reactions. No evidence of a Friedel-Crafts type of reaction between the $C_2H_4Cl_2$ and C_6H_6 could be found. In a mixt. of C_6H_6, BzCl and Cl no BzPh was formed with introduction of C_2H_4. C. J. WEST

***cis-trans*-Isomerism and steric hindrance. XII. *o*-Butylcyclohexanols.** G. VAVON AND A. GUEDON. *Bull. soc. chim.* **47**, 901–10(1930); cf. *C. A.* **24**, 1355.—A study of the *cis*- and *trans*-*o*-butylcyclohexanols (I) and their ethers was undertaken for comparison of their reaction velocities. *o-Butylcyclohexanone* (II) was prepd. by catalytic hydrogenation of *o*-BuC_6H_4OH (III) followed by oxidation with CrO_3. The catalytic hydrogenation of III with Pt black yielded butylcyclohexane and 60% of I. The semicarbazone of II m. 143–4°, from which was regenerated II, b. 90–1°, d_4^4 0.914, n_D^4 1.4603. Catalytic hydrogenation of the semicarbazone in aq. alc. contg. HCl yielded the semicarbazide, m. 96–7°; oxime of II m. 43–4°. II also was obtained by condensation of butanal with cyclohexanone (IV) and subsequent catalytic hydrogenation of the butylidenecyclohexanone in the presence of 5% NaOH according to the process of Grignard and Dubien (*C. A.* **19**, 1247). The fraction b_{16} 130–45° was not purified but directly dehydrated by distn. in the presence of 2% $(CO_2H)_2$ at 30–40 mm. The fraction now b_{20} below 100° gave with semicarbazide-HCl a compd. m. 166° which is the semicarbazone of IV. The main fraction b_{20} 105–20° was directly hydrogenated and yielded II. A 3rd way of obtaining II is by the action of Mg and BuBr on *o*-chlorocyclohexanone. Bu cyclopentyl ketone (V), b_{25} 104–6°, d_4^{23} 0.893, n_D^{23} 1.4479, is obtained as a by-product. The structure of V is proved by its synthesis from cyclopentanealdehyde and BuMgBr and subsequent oxidation of the secondary alc. obtained. The formation of a 5-C ring from the 6-C system is emphasized. *cis*-I was prepd. by Pt black hydrogenation of II in AcOH-HCl. After hydrolysis of the acetate formed it b_{9-10} 101–2°; dinitrobenzoate, m. 76°; acid phthalate, m. 58–9°; phenylurethan, m. 64–5°. *trans*-I, obtained in 87% yield by treating II with Na and alc., b_{16} 111–2°, d_4^{17} 0.9046, n_D^{17} 1.4654; dinitrobenzoate 72–3°; acid phthalate, m. 71°; phenylurethan, m. 68°. The esterification of the *cis*-form is slower than that of the *trans*-isomer; hydrolysis with 0.1 *N* NaOH of the 2 acid phthalates at 39° gives K_{trans}/K_{cis} = 3.6 in H_2O, 2.5 in 75% alc. E. G.-F.

Oscillating, puckered, centroid model for the benzene ring. MAURICE L. HUGGINS. *J. Am. Chem. Soc.* **53**, 1182–3(1931).—Brief discussion. C. J. WEST

Directing influence of certain groups in the benzene nucleus. G. BARGELLINI. *Mem. accad. Italia* (*Classe sci. fis mat. E nat.*) **1**, Chem. No. 3, 15 pp.(1930).—In a preceding paper (*C. A.* **23**, 3910) the influence of OH, *O*-alkyl, NH_2 and acylamino groups in directing halogens entering the C_6H_6 nucleus were studied. In the present paper the effect of NH_2 groups when para to each other and blocked by alkyl or acyl groups is studied. Previous work has shown that when an OH group is blocked by an alkyl, and at the *p*-position an NH_2 is blocked by an acyl group, then the first halogen enters a position ortho to the alkoxy, but a 2nd halogen enters ortho to the acylamino group. *E. g.*, $MeOC_6H_4NHAc$ forms successively, acetyl-2-bromo- and then *acetyl-2,5-dibromoanisidine*, m. 195°. Its constitution was proved by oxidation which gives 2,5-dibromoquinone. The rule is then that *when a deriv. of p-aminophenol is halogenated, which has an O-alkyl group as well as NHAc, the first halogen enters ortho to the O-alkyl group and the second ortho to the NHAc group.* A. W. CONTIERI

Catalytic hydrogenation of organic compounds over copper chromite. HOMER ADKINS AND RALPH CONNOR. *J. Am. Chem. Soc.* **53**, 1091–5(1931).—Details are given for decomposing $CuNH_4$ chromate for the prepn. of Cu chromite, which is shown to be quite superior in many respects to any catalyst hitherto used. Numerous aldehydes and ketones may be quantitatively and rapidly hydrogenated to the corresponding alcs.; this holds true not only for aliphatic CO compds. but also for aromatic ones and for keto esters and a keto alc. A carbinol group adjacent to a benzenoid ring may be completely reduced. NO_2 groups may be quantitatively reduced to primary amines without the simultaneous formation of secondary amines. An alkene linkage in a

hydrocarbon as well as in an acid or ketone may be hydrogenated without otherwise modifying the org. compd. Pyridinoid rings and C to N double bonds, as in anils, may be readily hydrogenated. The furanoid ring in furyl alc. may be readily broken with the formation of 1,2- and 1,5-pentanediols in good yields. The new catalyst is not active toward cyanides or toward benzenoid nuclei. It is not nearly so sensitive as Ni to S- or halogen-contg. impurities in the compd. to be hydrogenated. Its lesser sensitivity toward deactivation probably accounts for the fact that it is much more active after it has begun to act than is Ni, despite the fact that Ni is active at lower temps. No special app. such as a reduction furnace is needed and the catalyst need not be freshly prepd. before use. The catalyst ready for use does not change on standing in contact with air or moisture. It is not rapidly deactivated during use. The rate of hydrogenation of Me_2CO over Cu chromite is very much more rapid at higher pressures. With an av. pressure of 35 atms. the hydrogenation of 1.73 mols. with 1 g. of catalyst has proceeded to the extent of only 17% in 30 min., while at a pressure of 148 atms. 60% of the Me_2CO was reduced and at 212 atms. the reaction was 95% complete in 30 min. At the end of 1 hr. the percentage of hydrogenation was 22, 92 and 100 for the 3 pressures given above. Zn chromite has also been used as a catalyst but it is much less active than the Cu compd. and has been found to catalyze condensation. C. J. WEST

Organic syntheses facilitated by pressure. GILBERT T. MORGAN. *Chemistry and Industry* **50**, 104–9(1931).—A review with many references to the patent literature of important syntheses facilitated by pressure was presented by the Herter Memorial Lecturer in which the following were discussed: aromatic amines from phenols and NH_3; alkylanilines from anilines and alcs.; alkali fusions of substituted naphthalenesulfonic acids; formation of hydrocarbons, alcs., aldehydes, ketones, etc., by pressure reactions in the gas phase from CO and H_2 with various catalysts; dehydration of alcs. to form ethers; gaseous polymerization of C_2H_4; hydrogenation in general; oxidation in general; CO_2 and phenols as in the Kolbe synthesis for salicylates; CO_2 and aromatic hydrocarbons in the presence of $AlCl_3$ to give benzoic acid, toluic acid, etc.; anilines and CO_2 to form CO_2H acids, ketones and urea derivs. In autoclaves pressures from 50 to 300 atms. may be developed without personal risk, providing the temps. are not excessive; above 360° care must be taken. It is best to assume that with every autoclave in const. use there will come a time when failure is to be expected. It is believed that a systematic study of high-pressure reactions will in many cases lead to discoveries whereby the use of pressure will be partially or entirely avoided as in the amination of naphthols where a more efficient catalyst has led to a reduction from 50 to 5 atms. Under conditions of high temp. and pressure the oxides of C may be hydrogenated catalytically to yield a complex mixt. of alcs., aldehydes, acids and esters; these results are somewhat comparable with the transformations of photosynthesis. The more complex products of vital activity are missing from high-pressure syntheses probably because at the high temp. also involved, these substances are incapable of existence; more efficaceous catalysts by causing a lowering in the temp. might make the synthesis of such natural products possible. N. A. LANGE

Transformation of aldehydes into higher molecular amines. A. SKITA AND G. PFEIL. *Ann.* **485**, 152–73(1931); cf. *C. A.* **21**, 2876.—Previous work has shown that $EtCH{:}NC_6H_{11}$(I) on reduction with Pt and H gives $PrCHMeCH_2NHC_6H_{11}$(II). The present study is an extension of this observation. Catalytic reduction of $MeCH{:}NC_6H_{11}$ at room temp. and with a pressure of 3 atm. of H is complete in 0.5 hr., giving 8% of the Et deriv. (*picrate*, m. 231°), and 38.7% of *N-butylcyclohexylamine*, b. 202–4° (HCl salt, m. 290°); the latter also results in 51.5% yield by reducing *N-(2-buten-1-al)cyclohexylamine*, b_{18} 90–1°. Reduction of I gives 49% of II; II also results from *N-(2-methyl-2-penten-1-al)cyclohexylamine*, b_{15} 118–9.5°, in 49% yields; using an equiv. amt. of EtCHO with I increases the yield of II to 76.4%; II *HCl salt*, m. 139°; *phenylurea*, m. 99°. *Butyralcyclohexylamine*, b_{16} 85–7°, is reduced in 5 hrs., giving 75% of *N-(2-ethylhexyl)cyclohexylamine*, b_{14} 140–4°; this also results in 56% yield by reducing *N-2-ethyl-2-hexen-1-al)cyclohexylamine*, b_{12} 139–43°; *HCl salt*, m. 95°, *picrolonate*, m. 225–6° (decompn.). Reduction of isovaleralcyclohexylamine gives 50% of the *N*-iso-Am deriv., b_{11} 89–93° (*HCl salt*, m. 279–80°) and 15% of *N-(2-isopropyl-5-methylhexyl)cyclohexylamine*, b_{11} 143–5° (*HCl salt*, m. 105°; *acid oxalate*, m. 193.5–4.5°); *N-(2-isopropyl-5-methyl-2-hexen-1-al)cyclohexylamine*, b_{16} 146–52°, gives 61.5% of the same amine. Isovaleralethylamine is reduced in 3 hrs., giving 20% of the iso-Am deriv., and 16.4% of *N-(2-isopropyl-5-methylhexyl)ethylamine*, b. 213–20° (*picrolonate*, m. 221–2° (decompn.)). *N-Heptylcyclohexylamine*, b_{16} 132–5° (*HCl salt*, m. 211–2°); *N-(2-amylnonyl)cyclohexylamine*, b_{17} 208–10° (42.3% yield); *HCl salt*, m. 90°; *acid oxalate*, m. 153°; *N-(2-amyl-2-nonen-1-al)cyclohexylamine*, b_{11} 208–11°; reduction gives 25.8% of the

amine. Reduction of hydrocinnamalcyclohexylamine gives 15% of the 3-phenylpropyl deriv. and about 16% of *N-(2-benzyl-5-phenylamyl)cyclohexylamine*, whose *HCl salt* m. 169–70° and *acid oxalate* m. 172°; this also results in 69% yield by reducing *N-(2-benzyl-5-phenyl-2-penten-1-al)cyclohexylamine*, b_{16} 265–70° (partial decompn.). Catalytic reduction of a mixt. of I and AcH in AcOH gives, in addn. to $C_6H_{11}NH_2$, its Et, Bu and 2-methylamyl derivs., 29.5% of *N-(2-methylbutyl)cyclohexylamine*, b_{14} 96–101° (*HCl salt*, m. 234°; *phenylurea*, m. 118°); this also results in 61% yield by reducing *N-(2-methyl-2-buten-1-al)cyclohexylamine*, b_{15} 100–5°. I and BzH give 11% of *N-(2-methyl-3-phenylpropyl)cyclohexylamine*, b_{14} 165–72° (*HCl salt*, m. 184°; *phenylurea*, m. 116°); this also results in 60.5% yield from *N-(2-methyl-3-phenyl-2-propen-1-al)-cyclohexylamine*, b_{14} 168–76°. I and furfural give 8 7% of *N-(2-methyl-3-furylpropenyl)-cyclohexylamine*, b_{15} 167–75° (*HCl salt*, m. 180°); 0.7% of its *dihydro deriv.*, b_{12} 156–61°; and 8% of the *tetrahydro deriv.*, b_{18} 143–50° (*acid oxalate*, m. 165°). The same compds. are obtained on reducing *N-(2-methyl-3-furyl-2-propen-1-al)cyclohexylamine*, b_{12} 158–62°, in 7.3, 1.8 and 10.75% yield, resp. *Furfuralcyclohexylamine*, b_{18} 131.5–5.5°; reduction gives the *N-furomethyl deriv.*, b_{16} 123–4°; *phenylurea*, m. 113°. Isobutyralcyclohexylamine and HCHO give 64.8% of *N-(2,2-dimethyl-3-hydroxypropyl)cyclohexylamine*, b_{12} 123–5°, m. 38°; *HCl salt*, m. 224°; *phenylurea*, m. 150°; *di-Ac deriv.*, b_{16} 198–9°. This also results in 37.8% yield by reducing *N-(2,2-dimethyl-3-propanol-1-al)cyclohexylamine*, b_{12} 108–10°. These results indicate that the reaction proceeds through the hydrolysis of the amine to the aldehyde, which then forms a Schiff's base with the amine and as such is reduced. Only in the case of I is practically complete hydrolysis observed. The reaction does not occur with aromatic aldehydes of the type of BzH but does with the fatty-aromatic aldehydes, such as $PhCH_2CH_2CO_2H$.

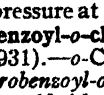
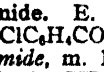
Fluosilicates of organic bases. II. C. A. Jacobson. *J. Am. Chem. Soc.* **53**, 1011–5(1931); cf. *C. A.* **23**, 117.—The *fluosilicates* of the following compds. were prepd. and the crystals photographed. *o-Tolidine*, m. 268–9°; *di-α-naphthylamine*, m. 218° (decompn.); *di-β-naphthylamine*, m. 236.3°; *di-m-nitroaniline*, m. 200°, *diphenylamine*, m. 169°; *m-phenylenediamine*, m. 243–4°; *p-phenylenediamine*, decomps. on heating; *diethylaniline*, m. 165.3°; *dinitrosodiphenylamine*, m. 124.5° (decompn.); *di-p-aminoazobenzene*, m. 220° (decompn.); *di-p-aminobenzoic acid*, m. 240 5°. The soly. in EtOH at 25° is given. C. J. West

Mechanism of chemical reactions. II. Mechanism of the synthesis of secondary and tertiary amines by reduction. Karl Kindler, W. Peschke and W. Dehn. *Ann.* **485**, 113–26(1931); cf. *C. A.* **17**, 2278.—$PhCH_2NH_2$ gives almost quant. $(PhCH_2)_2NH$ on reduction with Pd and H in 96% EtOH for 3 hrs. $PhCH_2CH_2NH_2$ (I), similarly treated, gives only 10% of the sec. amine. This reaction is assumed to proceed as follows: $RCH_2NH_2 \longrightarrow RCH{:}NH \longrightarrow RCH_2N{:}CHR \longrightarrow (RCH_2)_2NH$. A mixt. of I and $PhCH_2OH$ in $C_6H_4Me_2$, reduced as above for 3 hrs., gives a mixt. of 6% $(PhCH_2CH_2)_2NH$ but principally $PhCH_2CH_2NHCH_2Ph$ (II). Here it is assumed that the $PhCH_2OH$ is reduced to BzH, which then reacts to give $PhCH{:}NCH_2CH_2Ph$ (III), and this is reduced to II. III, prepd. from BzH and I, is nearly quant. reduced to III in 5 min. $PhCSNH_2$ (IV), on reduction with Al-Hg in moist Et_2O, gives 85% of $PhCH_2NH_2$ and 8% $(PhCH_2)_2NH$, while $PhCH_2CSNH_2$ (V) gives 26% of I and 66% $(PhCH_2CH_2)_2NH$. In 55, 90 and 145 min., resp., 84, 94 and 99% of IV and 35, 41 and 31% of V, resp., were reduced at 20° in moist Et_2O. Both primary and sec. amines result on reduction of $PhCH_2CH(OH)NH_2$ and $PhCH_2CH{:}NH$. Reduction of $PhCH_2CH(OH)NMe_2$ with Al-Hg gives $PhCH_2CH_2NMe_2$, b. 204–6°. In the reduction of $PhCH_2CN$ in AcOH-$AcONH_4$ with Pd and H, the Schiff base is an intermediate product and the final product contains about 60% of $(PhCH_2CH_2)_2NH$. The amt. of sec. amine formed is much larger in a neutral or alk. medium than in an acid medium. PhCN in AcOH is catalytically reduced at 35° and 2.5 atm. H in 20 min., giving 99% of primary amine (VI); in 96% EtOH, 70% is reduced after 180 min., giving 96% VI and 4% sec. amine; $PhCH_2CN$ is 95% reduced in AcOH after 420 min., giving 50% primary and 40% sec.



amine; in EtOH, 50% is reduced in 180 min., giving 17% primary and 68% of sec. amine. $PhCH_2CN$ and Pr_2NH, catalytically reduced in EtOH, give a mixt. of 24% of $(PhCH_2CH_2)_2NH$ and 60% of $Pr_2NCH_2CH_2Ph$. C. J. WEST



Derivatives of anesthesin. L. CONIGLIO. *Rend. accad. sci. Napoli* [3], **36**, 56–60 (1930).—New derivs. were prepd. by condensing anesthesin, p-$H_2NC_6H_4CO_2Et$ (I), with $Me_2CHCHBrCOCl$ (II), BzCl (III), phthalyl chloride (IV) and AcCl (V). The aim was to study the pharmacol. action of the derivs. in relation to the new radicals introduced into the mol. *N-α-Bromoisovaleryl deriv.* was prepd. from 0.60 g. I and 7.96 g. II; mixed in a separatory funnel with about 50 cc. of a 2% soln. of equal parts NaOH and KOH; the caseous white mass was filtered, washed repeatedly with H_2O and dried. The product was sol. in all org. solvents; a pure material, m. 115°, was obtained by dissolving in acetone and pptg. with petroleum ether. *N-Bz deriv.* from 6.60 g. I and 5.62 g. III, according to the Schotten-Baumann method, washed with H_2O and dried *in vacuo* over H_2SO_4, it crystallizes in white needles from alc., sol. in acetone, $CHCl_3$, AcOH and Et_2O, insol. in H_2O, m. 15°. *N-Phthalyl deriv.*, $C_6H_4(CO)_2NC_6H_4CO_2Et$, from 6.60 g. I and 7.12 g. IV in benzene and cooled; the white mass filtered, washed with H_2O and dried *in vacuo* over H_2SO_4, long needles from alc. crystallize out, sol. in warm AcOH and acetone, very sol. in cold $CHCl_3$, insol. in Et_2O and in H_2O, m. 152°. *N-Ac deriv.* from 6.60 g. I in 20 cc. benzene and 3.12 g. V warmed on the water bath and cooled, filtered, washed repeatedly with Et_2O and dried over $CaCl_2$, sol. in alc. from which it is pptd. with Et_2O, sol. in H_2O, acetone, AcOH, slightly sol. in $CHCl_3$, insol. in Et_2O and MeOH, m. 181°. The pharmacol. properties are being investigated. P. M.

***p*-Bromoanilides of isobutyric and isovaleric acids.** MARGUERITE KUEHN AND S. M. MCELVAIN. *J. Am. Chem. Soc.* **53**, 1173–4(1931).—The derivs. were prepd. from the acid chloride and p-$BrC_6H_4NH_2$; *p-bromoisobutyranilide*, m. 150–1°; *p-bromoisovaleranilide*, m. 128–9°. C. J. WEST

The organic sulfonic and sulfinic acids. JULIUS V. BRAUN AND KARL WEISSBACH. *Ber.* **63B**, 2836–47(1930).—In contrast to the large amount of work which has been done on the imidocarboxylyl chlorides, no attempts had ever been made to prep. the imidosulfinyl chlorides, RSCl:NR′, and the only expt. in the field of the SO_3H acids recorded in the literature indicated that the relations are materially different from those in the CO_2H acid series; PCl_5 reacts with $PhSO_2NHPh$ only after long heating and the $-SO_2NH-$ group is not attacked, only chlorination of the Ph nucleus taking place. $PhSO_2NHEt$ also reacts only at 100° and very slowly, forming (probably as the result of chlorination outside of the $-SO_2NH-$ group) a very difficultly separable oily mixt. boiling in a high vacuum within wide limits (100–70°). The hope that in the absence of aromatic residues the results would be more clear-cut was completely fulfilled. Expts. on monoalkylamides of $BuSO_3H$, iso-$AmSO_3H$ and cyclohexylsulfonic acid gave the following results: PCl_5 reacts with compds. like $BuSO_2NHEt$ considerably more sluggishly than with the amides of non-aromatic CO_2H acids but, without recourse to extreme conditions, gives compds. having the expected compn. $BuS(:O)Cl:NEt$ and whose properties were, at first, surprising; the compds. are stable to heat and can therefore be distd.; their Cl is strikingly unreactive; with H_2O and alc. they react only very slowly, with amines almost not at all. The action of an excess of PCl_5 results in a very slow chlorination of the C atom adjacent to the $-S(:O)Cl<$ group, but with still more Cl under more vigorous conditions the grouping $>C.S(:O)Cl:N-$ is finally converted into $>C.SCl_3:N-$, in which the 2 new Cl atoms (but only these) are as reactive as the Cl in the imidocarboxylyl chlorides; even cold H_2O converts the compds. back into the $>C.S(:O)Cl:N-$ derivs. It is believed that these properties are due to the "imidosulfonyl chlorides" really having a 3-membered ring structure (I) or, from the standpoint of the modern theory of semi-polar union, the structure II. It had been hoped that this might be confirmed by a detn. of the parachor, but the usual parachor consts. do not hold for this type of compds. and the values obtained differed widely from those calcd. If the peculiar behavior of the "imidosulfonyl chlorides" is due to the presence of O, the SO_2H derivs. should show no such anomaly, and as a matter of fact compds. like BuSONHEt react readily with PCl_5 to give HCl, $POCl_3$ and liquid chlorinated products reacting violently with H_2O and which cannot be distd. without decompn. even in a high vacuum. The prepn. of a no. of amides of non-aromatic sulfinic acids was used to study a question in this field which hitherto had been tested experimentally only with $PhSO_2H$, *viz.*, the dismutation of these acids ($2\,RSO_2H = RSO_2SR + RSO_3H + H_2O$). The distn. without decompn. of the $BuSO_3H$, iso-$AmSO_3H$ and cyclohexylsulfonic acid made it possible to follow the reaction quantitatively. While the mol. of RSO_2H which is oxidized at the expense of the other 2 mols. cannot be replaced by o- or p-$C_6H_4(OH)_2$ as O acceptor, it can be replaced by mercap-

tans: $2RSO_2H + HSR' = RSO_2SR + 2H_2O + R'_2S_2$. Sulfinic esters and sulfinyl chlorides, unlike the free acids, are relatively very stable but the conversion of the chlorides into thiosulfonic acids can be readily effected with Na mercaptides or, even more conveniently, with dithiocarbamates as O acceptors: $2R_2NCS_2H.NHR_2 + 2ClSOR = [R_2NC(:S)S]_2 + 2ClH.NHR_2 + R'SO_2SR'$. Sulfenyl chlorides react according to the equation $2R_2NCS_2H.NHR_2 + 2ClSR' = [R_2NC(:S)S]_2 + 2ClH.NHR_2 + R'_2S_2$. The $AlkSO_2H$ derivs. were prepd. by treating the alkyl bromides in Et_2O with Mg and SO_2 and converting the resulting acids into the chlorides with $SOCl_2$, the $AlkSO_3H$ derivs. by oxidizing the crude $(AlkSO_2)_2Mg$ with $KMnO_4$ and converting the $AlkSO_3H$ into the chlorides with PCl_5. The liquid $BuSO_2H$ no longer dissolves clear in H_2O after standing a short time at room temp.; at 100° (in N) the disproportionation is complete in about 1 hr. and the H_2O-insol. part $b_{0.2}$ 126–8° and has the compn. of *Bu butylthiosulfonate*, while the strongly acid, H_2O-sol. part is *butylsulfonic acid*, $b_{0.2}$ 145°. *Butylsulfinyl chloride*, light yellow, $b_{0.1}$ 38°, b_{12} 78°, fumes in moist air, is energetically hydrolyzed by H_2O, is stable in the absence of O, even on heating, but in dry air slowly changes into $BuSO_2Cl$. The *Et ester*, b_{12} 85°, and *ethylamide*, b_{10} 108–10°, show the same oxidizability and non-dismutation. *iso-Am isoamylthiosulfonate*, b_{12} 176–80°. *Isoamylsulfonic acid*, $b_{0.2}$ 176–8°. Isoamylsulfinyl chloride, $b_{0.1}$ 60–2°, b_{12} 91–2°. *iso-Am ester*, b_{12} 98°, remains unchanged at 100° in N. *Ethylamide*, b. 120° in a high vacuum. *Cyclohexylsulfinic acid*, yellowish oil solidifying on strong cooling to crystals, m. 33–5°, and having approx. the compn. of a *monohydrate*. *Cyclohexyl cyclohexylthiosulfonate*, faintly yellow, $b_{0.1}$ 184–6°. Cyclohexylsulfonic acid, $b_{0.1}$ 178–80°, readily absorbs H_2O to form a monohydrate, m. 92°, the m. p. given by Borsche and Lange for the acid. *Butylsulfonethylamide*, $b_{0.1}$ 120–2°. *Ethylimidobutylsulfonyl chloride*, $b_{0.2}$ 124–6°. *Isoamylsulfonethylamide*, faintly yellow oil; *imido chloride*, $b_{0.2}$ 128–30° (with 2 mols. PCl_5 is obtained a *di-Cl compd.*, $b_{0.5}$ 128–30°, which is as resistant to hydrolysis as the mono-Cl compd. and probably has the structure $C_4H_9CHClSCl.O.NEt$). *Cyclohexylsulfonethylamide*, b_{18} 183–5°, m. 72°; *imido chloride*, $b_{0.7}$ 131–2°, m. 73–4°. With 4 mols. PCl_5 is obtained a brownish oily *compd.* $C_8H_{15}NCl_4S$, b_1 140–50°, quickly converted by cold H_2O into a *compd* $C_8H_{15}ONCl_2S$, m. 156°, in which both Cl atoms are very firmly held. *Cyclohexylsulfonpropylamide*, m. 78°, reacts so slowly with PCl_5 that even after 2.5 hrs. at 100° with 2 mols. PCl_5 it gives only 60% of a mono-Cl compd. $b_{0.1}$ 145–60°; the *heptylamide*, $C_8H_{11}SO_2NHC_7H_{15}$, m. 72°, behaves in the same way. *p*-$O_2NC_6H_4SCl$, $b_{0.1}$ 125°, with piperidine piperidyldithiocarbamate in Et_2O yields 1 mol. piperidine-HCl and a mixt. of $(p\text{-}O_2NC_6H_4)_2S_2$ and piperidylthiuram disulfide which could not be sepd. anywhere nearly quantitatively but distn. in a high vacuum gave a product sepd. by crystn. from alc. into the $(O_2NC_6H_4)_2S_2$ and dipiperidylthiourea.

Separation and synthetic preparation of phenol. TADASHI MIZOSHITA. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 36.—High-temp. coal tar yields only 0.1897% PhOH and 0.569% cresols. 1 PhCl + $2Na_2CO_3$ gives 84% PhOH by heating under pressure at 320° for 2 hrs. with Cu as the catalyst. V. F. HARRINGTON

***N*-*o*-Chlorobenzoyl-*o*-chlorobenzenesulfonamide.** E. WERTHEIM. *J. Am. Chem. Soc.* **53**, 1172–3(1931).—*o*-$ClC_6H_4SO_2NH_2$ and *o*-ClC_6H_4COCl, heated at 180–90° for 1 hr., give *N-o-chlorobenzoyl-o-chlorobenzenesulfonamide*, m. 154–5°. Attempts to prep. from this diphenic sulfinide failed; Cu and NaI in AmOH gave an impure compd., m. 255–8°, with 8.67% S, which had a bitter taste. C. J. WEST

Methylation of alcoholic hydroxyl from the standpoint of the electron theory. JULIUS V. BRAUN, ERNST ANTON AND KARL WEISSBACH. *Ber.* **63B**, 2847–61(1930).—The old valence doctrine does not serve to explain why the proximity of a Ph nucleus or a double bond to the HO group in such compds. as $PhCH_2OH$, $PhCH{:}CHCH_2OH$, dioxindoles, morphine, codeine and the 2 methylmorphimethins makes the HO group so easy to methylate, as compared with the alcs., with Me_2SO_4 and alkali, but the electron theory offers a plausible explanation. The pair of electrons in a homeopolar combination XY is shifted nearer to the one or the other of the partners in the union, depending on the chem. nature of X and Y and on the near and, to some extent also, the more distant surroundings. The Ph nucleus and the double bond, which

exert an attraction on electrons, must produce in a compd. Ph.C....C.O.H or —CH:CH.C....C.O.H a shifting of the electrons toward the left, imparting to the end H atom a weak positive charge and making it more reactive. If this basic assumption is correct, it follows that (1) the inductive or attractive influence of a Ph nucleus or a double bond must diminish greatly with the distance from the HO group; (2) an influence as strong as, or stronger than, that of a Ph nucleus or C:C bond must be exerted by every dipole with its + side turned toward the HO group (*e. g.*, the groups $\bar{O}{=}\overset{+}{C}<$, $\bar{N}{:}\overset{+}{C}-$, etc.); (3) the effect must be most pronounced when in the chain contg. the HO group there is an element having the character of a positively charged ion (*e. g.*, $\bar{A}c.\overset{+}{N}\,C.....C.O.H$). The behavior of the morphine alkaloids mentioned above suggested that it is not the aromatic nuclei or the double bonds which activate the H of the HO group but that under the influence of the Me_2SO_4 the N is converted into a quaternary form and it is the NH_4 ion which acts on the HO group. To test these views a long series of comparative expts was made; the values given below represent the % yield of Me ether obtained from the different HO compds. under identical conditions: $PhCH_2OH$ (I), 64; $PhCH_2CH_2OH$ (II), 19; $Ph(CH_2)_3OH$ (III), 5; $Ph(CH_2)_5OH$ (IV), 0; $PhCMe_2OH$ (V), 0; $PhCH{:}CHCH_2OH$ (VI), 53; O.CH:CH.CH:C-CH_2OH (VII), 70; $CH_2{:}CHCH_2OH$ (VIII), >20; PrOH (IX), 0; AmOH (X), 0; $C_7H_{15}OH$ (XI), 0; $C_5H_{10}N(CH_2)_2OH$ (XII), 100; $Me_2N(CH_2)_3OH$ (XIII), 100; $PhNMe(CH_2)_3OH$ (XIV), almost 100; $C_5H_{10}N(CH_2)_4OH$ (XV), about 50; $C_5H_{10}N(CH_2)_5OH$ (XVI), 0; $Me_2N(CH_2)_5OH$ (XVII), 0; 2-dimethylamino-3-hydroxytetralin (XVIII), 100; 2-β-hydroxyethylpiperidine (XIX), 100; dihydrocodeine (XX), almost 100; 5,2-$Me(Me_2N)C_6H_2CH_2OH$ (XXI), 60; tropine (XXII), 0; $Me_2NCMe_2CH(OH)Me$ (XXIII), 0; $PhSO_2NMe(CH_2)_3OH$ (XXIV), 0; $NC(CH_2)_2OH$ (XXV), >50; $EtSO_2CH_2CH_2OH$ (XXVI), 100; $Me_2SiCH_2CH_2OH$ (XXVII), 50; $Me_2SiCH_2CH_2CH_2OH$ (XXVIII), ?; $MeCH(OH)CO_2H$ (XXIX), 15?; $PhCH(OH)CO_2H$ (XXX), 70; $PhCH(CH_2OH)CO_2H$ (XXXI), 40; phthalide (XXXII), 40; phenylparaconic acid (XXXIII), 40. Comparison of compds. I–IV shows how rapidly the influence of the Ph on the HO group decreases with the distance between them. This is also true of the 2 unsatd. alcs. tested (VI, VIII). Satd. aliphatic alcs. are resistant toward Me_2SO_4 and alkali (IX, X and XI). The furan ring is similar to the C_6H_6 ring (VII). CN and the more strongly dipolar SO_2 have as great or a greater effect than the aromatic nucleus of the C:C bond (XXV, XXVI). In compds. with basic N together with HO, the effect is greater than in aliphatic-aromatic alcs. (XII compared with II, XIII and XIV with III). The influence of N is still strong on a δ-HO (XV) but is no longer shown on ε-HO groups (XVI, XVII). That the influence of the N is due to its forming a quaternary salt is indicated by the behavior of XXI and XXIV; its greater influence, as compared with that of the Ph nucleus or C:C bond, is shown by the fact that XX is methylated to about the same extent as codeine. The non-methylation of XXII is thought to be due to the branching of the chain between the N and the HO; the base XXIII and the carbinol V behave similarly. That it is not the secondary nature of the HO or the position of the N in the ring that prevents the methylation of XXII is shown by the behavior of the alkamines XVIII and XIX. The electron attraction should be weakened by increasing the vol. of the ionized atom $X.\overset{+}{C}....C.O.H$; to test this point, the sulfonium compds. XXVII and XXVIII were studied but no clear picture of the methylation of XXVIII could be obtained; XXVII, however, acted as had been expected. Of the simple aliphatic HO acids, only XXIX gave results which were at all definite; they indicated that the influence of the C.O is not inordinately great, as also indicated by comparison of XXX with I and of XXXI with II. In the reaction between Me_2SO_4 and an activated HO group it may be assumed that as the result of an attraction of the positively charged S by the weakly negatively charged O in the OH group there is formed an intermediate addn. product $\begin{matrix}R\\H\end{matrix}\!\!>\!O....SO_2(OMe)_2$ which then in some way undergoes further reaction. The extraordinary ease with which alkamines and HO acids are methylated is of practical interest for purposes of prepn. and in questions of structure. The HO bases prepd. from compds. of the type ArCH:CH— by addn. of Br, boiling with H_2O and treatment with amines are formed through an oxide

ArCH.CH.O which may give either ArCH(NHR)CH(OH)— or ArCH(OH)CH(NHR)–.

No means of distinguishing between these two possibilities was hitherto available, but methylation will give an ether which must be identical with or different from the compd. ArCH(OMe)CH(NMe$_2$I)— obtained by treating ArCHBrCHBr— with MeOH, then with NH$_2$Me and methylating exhaustively. By this means it was found that the hydroxymethylamino *base* (**XXXIV**) obtained by Mannich from isosafrole really has the structure $CH_2O_2C_6H_3CH(NHMe)CH(OH)Me$ which he assigned to it without any real proof. The methylations were carried out under as nearly identical conditions as possible; the substance dissolved or suspended in 10 parts H_2O at 5° was treated with 6 mols. Me_2SO_4 and 14 mols. 10% NaOH, shaken 5 min. and allowed to stand (the temp. rose to 50–5°) 15 min. The methiodide of **XII** forms a red *chloroplatinate*, m. 228°, and a *chloroaurate*, m. 243°; the methiodide of the Me ether gives an orange *chloroplatinate*, m. 234° (decompn.), and a *chloroaurate*, m. 108°. *Methiodide* of the Me ether of **XIII**, m. 221°; *chloroplatinate*, decomps. 235°. *Methiodide* of **XIV**, m. 132°; *Me ether*, m. 119–21°. *Methiodide* of **XV** Me ether, semi-oily. **XVIII**, m. 31°; *Me ether methiodide*, m. 223°; *methochloride*, m. 230°; *chloroplatinate*, light orange, m. 229°. **XXIX** with Me_2SO_4 forms a quaternary salt which cannot be pptd. out; the compn. of the *chloroplatinate*, $C_{20}H_{44}O_2N_2Cl_6Pt$, m. 212°, shows that both the HO and NH groups are methylated; with MeI is obtained a *methiodide*, decomps. 235°, the compn. of whose *chloroplatinate*, $C_{18}H_{40}O_2N_2Cl_6Pt$, yellow, m. 204°, shows that the HO group has remained intact. *Me ether* of **XXI**, b_{12} 120–5°; *picrate*, m. 155°; *chloroplatinate*, m. 172°; *methiodide*, m. 115° (effervescence) (the corresponding derivs. of **XXI** m. 157°, 180°, 147°, resp.). *Methiodide* of **XXIII**, m. 172° (foaming). **XXIV**, from $PhSO_2NNaMe$ and $Cl(CH_2)_3OH$ on the H_2O bath, $b_{1.5}$ 194°, $b_{0.3}$ 167°. Ephedrine with Me_2SO_4 readily yields the quaternary salt of the *Me ether;* the corresponding *iodide*, $C_{13}H_{22}ONI$, m. 190°, smoothly loses MeI when heated *in vacuo*, yielding the *Me ether*, b_{16} 116°; *picrate*, m. 166–8°. α-Methoxy-β-bromodihydrosafrole (**XXXV**), obtained from isosafrole dibromide (**XXXVI**) with MeOH, and which certainly has the MeO group on the α-C atom, gives with Me_2SO_4 and then KI an unusually hygroscopic quaternary *iodide* (**XXXVII**), yielding a *chloroplatinate*, m. 216°, while the hydroxybromoisosafrole from **XXXVI** and H_2O yields, together with a little **XXXVII**, chiefly the non-hygroscopic *methiodide*, m. 190°, of **XXXIV**; *chloroplatinate*, m. 198°. *β-Hydroxydiethyl sulfone* (**XXVI**), from $EtSO_2Na$ and $ClCH_2CH_2OH$ in alc. on the H_2O bath, b_{12} 193–5°, m. 46°; *Me ether*, b_{12} 142–4°. *Dimethyl-β-hydroxyethylsulfonium iodide* (**XXVII**), from $MeSCH_2CH_2OH$ and MeI, m. 60–2°, absorbs moisture from the air (*chloroplatinate*, red-brown, m. 80–1°). *γ-Hydroxypropyl homolog* (**XXVIII**), m. 52–5° (*chloroplatinate*, orange, m. 115°). **XXIX** with Me_2SO_4 gave a small quantity (1.5 g. from 10 g. **XXIX**) of a compd., b_{12} 95–6°, having the compn. of the *Me ether* of **XXIX**. The Me ether of **XXX**, m. 71°, $b_{0.4}$ 121–2°. *Me ether* of **XXXI**, $b_{0.3}$ 134–6°, m. 62°; *chloride*, $b_{0.5}$ 88°, reacts readily with C_6H_6 and $AlCl_3$ to give the *ketone* $PhCH(CH_2OMe)COPh$, yellowish, $b_{0.2}$ 139–41°, converted by concd. HCl into the *ketone* $PhCH(CH_2Cl)COPh$, light yellow, $b_{0.5}$ 139–40° with some loss of HCl. **XXXII** gives the *acid* $o\text{-}HO_2CC_6H_4CH_2OMe$, m. 93–4°, $b_{0.5}$ 121–5°, does not form a chloride with $SOCl_2$ but loses MeCl with regeneration of **XXXII**. **XXXIII** gives a *compd.* $b_{0.5}$ about 155°, m. 95–6°, having the compn. of (*α-methoxybenzyl*)-*succinic anhydride*, and giving the *acid* m. 140°, when pptd. from Na_2CO_3 with acids.

C. A. R.

Derivatives of chloroacetylated phenols and phenol-alcohols. A. LAKNER. *Magyar Chem. Folyoirat* **35**, 151–5(1929).—ICH_2CO derivs. of di-HO derivs. of C_6H_6, like $ClCH_2CO$ derivs., are hydrolyzed by NH_3. With $AgNO_2$ halogenoacetylphenols react vigorously at 96°, affording dinitro derivs. and Ag halogenoacetate; AgCN behaves analogously. The following are described: *chloroacetates* of *pyrocatechol*, m. 56°, b_{10} 185–6°; *resorcinol*, m. 76°, b_5 191–2°; *quinol*, m. 126°; *iodoacetates*, m. 48–9°, 59–60°, 112–3°, resp. Quinol chloroacetate forms with $PhNMe_2$ an equimol. *compd.*, m. 152–3°, decomp. 156–7°. *Phenylethyl aminoacetate*, m. 115°; *phenylpropyl aminoacetate*, m. 105°.

B. C. A.

Propargyl ethers of phenol. CHARLES D. HURD AND FRANK L. COHEN. *J. Am Chem. Soc.* **53**, 1068–77(1931).—PhC:CBz (I) was obtained from PhC:CCOCl and EtOH, giving the Et ester and reacting this with PhMgBr. The yield of the ester is 65% and of the ketone 85%; the ketone b_{15} 200–2° and m. 53–5°. $PhC:CCPh_2OH$ results in 65–70% yield from BzPh and PhC:CNa. MeC:CH and EtMgBr give a Grignard reagent which reacts with Me_2CO to give 47% of *2-methyl-3-pentin-2-ol* (*trimethyl propargyl alc.*) (II), b_{16} 75–7°, n^{20}_D 1.4193; a by-product is *2-methyl-1-penten-3-ine*,

CH_2:CMeC:CMe (III), b. 75–7°, n_D^{20} 1.4002. 1-Phenylethinylcyclohexan-1-ol, b_1 166–9°, m. 58–60°. PhC:CNa and *p*-$Me_2NC_6H_4Bz$ give 50% of *α,γ-diphenyl-α-p-dimethylaminophenylpropargyl alc.*, m. 144–5°. II gives a *chloride*, light yellow, b_{47} 57–61°, n_D^{20} 1.4143 (33% yield). *γ-Methylpropargyl chloride* (*1-chloro-2-butine*), light yellow, b. 81–4° (44% yield). *Triphenylpropargyl Ph ether* (IV), from the chloride and PhONa in 70% yield, m. 90–90.5°; *trimethylpropargyl Ph ether* (V), viscous yellow oil, n_D^{20} 1.3408; *γ-methylpropargyl Ph ether* (VI), b_{25} 123–6°, n_D^{20} 1.3894 (57% yield). IV, heated slowly and uniformly to 310°, gives PhOH and *9-phenylethinylfluorene*, yellow, m. 98–100°; this was also prepd. from 9-chlorofluorene and PhC:CNa. Both V and II decomp. on heating into PhOH and III. When refluxed, VI changed primarily into a tar, the apparent mol. wt. of which was 400. No simple allenes were found although they may have been the precursors of the tars. C. J. West

Bromine derivatives of certain mixed ethers and some of their reactions. L. Chas. Raiford and Louis H. Howland. *J. Am. Chem. Soc.* 53, 1051–7(1931).—*Pentabromophenyl alkyl ethers: iso-Pr*, m. 86° (nearly quant. yield); *Bu*, m. 79–80° (quant. yield); *iso-Bu*, m. 92–3° (45% yield); *sec-Bu*, m. 57–8° (25% yield); *iso-Am*, m. 64–5° (quant. yield); no reaction was obtained with *tert*-Bu or *α*-Am halides. Four methods were studied for splitting the ethers: (1) glacial AcOH soln. of ether and PBr_3 to which the calcd. amt. of H_2O was gradually added was heated under a reflux; (2) the mixt. in (1) was heated in a sealed tube at 135–50° for 12–15 hrs.; (3) Br was dropped into a C_6H_6 soln. of the ether contg. I as a catalyst; (4) the ether, excess Br and about 1% Al as $AlBr_3$ reacted at room temp. for 2 days. Of the tri-Br derivs. of the Ph alkyl ethers, only iso-Pr and *sec*-Bu were completely split by (1); these were also split by (3) (others not studied); Me, Et, Pr, iso-Bu and iso-Am were completely split by (2) but showed no reaction with (1). Of the penta-Br derivs., iso-Pr and *sec*-Bu were completely split by (1); Me, Et, Pr, Bu, iso-Bu and iso-Am were completely split by (2); Me, Et and iso-Pr showed no reaction with (3); the following % of Br_5COH were obtained in (4): Me 80; Et 40; Pr 40; iso-Pr 60; Bu 30; iso-Bu 20; *sec*-Bu 70; iso-Am 30. *2,4-Dichlorophenyl allyl ether* (I), b_{25} 144–5°; *3,5-di-Br deriv.* (II), b_{10} 145°; *2,6-di-Br deriv.* (III), b_{10} 132–3°; *penta-Br deriv.* (IV), m. 167–8°. I and Br in $CHCl_3$ at 0° give the *β,γ-di-Br deriv.*, b_{10} 188° (95% yield); II gives the *2,3,4,5-tetra-Br β,γ-di-Br deriv.*, m. 123–4° (97%); III gives the *β,γ-di-Br deriv.*, m 48–9°, as does IV, m. 122–3° (96 and 94%, resp.). Alc. KOH transforms these into derivs. of *Ph propargyl ethers: 2,4-di-Cl*, liquid, decomps. on distn. *in vacuo*; *2,4-di-Br*, m. 65°; *2,6-di-Br*, m. 58–60°; *2,4,6-tri-Br*, m. 136–7°; the yields are 97–9%. The *Ag salts* (with 1 mol. $AgNO_3$) of these ethers were prepd., as well as the *Cu* and *Hg salts* of the 2,4-di-Br and 2,4,6-tri-Br derivs. The HBr evolved in the bromination of Ph alkyl ethers may split them unless AcONa is present. The splitting is most complete when the alkyl group is connected through a sec. or tert. C atom. Ph allyl ethers contg. 2 or more Br atoms in the nucleus could not be rearranged by heat. C. J. West

Effect of substituents on certain physical properties of benzene picrate. O. L. Baril and E. S. Hauber. *J. Am. Chem. Soc.* 53, 1087–91(1931).—The addn. of HO groups to benzene picrate (I) lowers the m. p. and deepens the color of the picrate formed; the addn. of Me groups to I raises the m. p. of the product and deepens the color of the picrate less than the HO group. The addn. of Me groups to a side chain of I gradually increases the m. p. and deepens the color of the picrate; this increase is more rapid than when a corresponding no. of Me groups are substituted in the ring. The sym. tri-HO and tri-Me derivs. of I are the darkest and the color of the picrates become lighter as we approach the 1,2,3-derivs. The same deepening of color was obtained with the Me derivs. of $C_{10}H_8$. Unsatn. in the side chain yields a very unstable picrate. In the following list of *picrates* the color and m. p. are given: C_6H_6, 83.9°; PhMe, light yellow, 88.2°; PhEt, light yellow, 96.6°; PhPr, yellow, 103.5°; *o-*, *m-*, and *p*-$C_6H_4Me_2$, lemon-yellow, 88.5, 90–1.5° and 90.5, resp.; 1,2,3-$C_6H_3Me_3$, yellow, 89.5°; 1,2,4-$C_6H_3Me_3$, yellow, 96–7°; 1,3,5-$C_6H_3Me_3$, bright yellow, 96.6°; 1,2,3,4-$C_6H_2Me_4$, golden yellow, 92–5°; C_6HMe_5, golden yellow, 131°; C_6Me_6, orange-yellow, 170°; all except the last 3 of these are unstable, decompg. in the air. PhOH, yellow, m. 83.1°; *o-*, *m-* and *p*-$C_6H_4(OH)_2$, orange-yellow (*o-* and *m-*) and light yellow, m. 122°, 89–90° and 115–7°, resp.; 1,2,3-$C_6H_3(OH)_3$, lemon-yellow, 128–9°; 1,2,4-$C_6H_3(OH)_3$, orange-red, 96°; 1,3,5-$C_6H_3(OH)_3$, brown, 101–3°; *o-*, *m-* and *p*-MeC_6H_4OH, orange-yellow, yellow and bright red, m. 88°, 61.6° and 64–5°, resp.; orcinol, orange-yellow, 92°; 1,2,4-, 1,3,2- and 1,4,2-$Me_2C_6H_3OH$, chrome-yellow, orange-yellow and orange, m. 83.8°, 50–3° and 81–2°, resp. $C_{10}H_8$, yellow, 149°; *α-* and *β-*Me derivs., lemon-yellow, 140–1° and 115–6°, resp.; *α-* and *β-*Et derivs., lemon-yellow and yellow, m. 97.4 and 69–70°, resp.; *α-* and

β-Pr derivs., yellow, m. 140–1° and 89–90°, resp.; α- and β-Bu derivs., orange-yellow, m. 104–5° and 71–3°, resp.; 1,4- and 2,6-di-Me derivs., orange-yellow, m. 139–40° and 141–2°, resp.; 1,2,6-tri-Me deriv., orange-yellow, m. 121–2°; α- and β-$C_{10}H_7OH$, orange-yellow, m. 188.5° and 155.5°, resp.; anthracene, ruby-red, m. 138°; hexa-Me deriv., dark brown, m. 203°; phenanthrene, orange-yellow, m. 132.8°; acenaphthene, orange-red, m. 160.5°; stilbene, red, m. 90–1°; fluorene, red-brown, m. 77°; pyrene, red, m. 220°. C. J. West

Phenyl ethers. Manfred Oesterlin. *Monatsh.* **57**, 31–44(1931).—PhONa and *p*-BrC_6H_4OMe with Cu at 200–10° for 4 hrs. give *p-methoxydiphenyl ether*, b_{14} 163–5°; $AlCl_3$ in C_6H_6 splits off the Me group, giving the *p-HO deriv.* (I), m. 84°; bromination (KBr and $KBrO_3$ with concd. H_2SO_4 in CS_2) gives 82% of the *p'-Br deriv.* (II), m. 85°. I in KOH and *p*-BrC_6H_4OMe with Cu at 210° for 4 hrs. give *p-methoxy-p'-phenoxydiphenyl ether*, m. 82°; $AlCl_3$ gives the *p-HO deriv.*, m. 87°. *p*-$MeOC_6H_4OH$ and *p*-BrC_6H_4-OMe with Cu and 80% KOH give 65% of *p,p'-dimethoxydiphenyl ether*, m. 102°; the *di-HO deriv.*, m. 160°. *p*-$MeOC_6H_4OH$ and *p*-$C_6H_4Br_2$ with KOH and Cu at 200–10° for 5 hrs. give *di(p-methoxyphenyl) hydroquinone ether* (*p*-$MeOC_6H_4O)_2C_6H_4$; this also results from II and *p*-$MeOC_6H_4OH$ with Cu and KOH at 210° for 4 hrs. The *di-p-HO deriv.*, m. 188°. *p*-$MeOC_6H_4OH$ and (*p* $BrC_6H_4)_2O$ give *p-di(methoxyphenyl)dioxydiphenyl ether*, $(MeOC_6H_4OC_6H_4)_2O$, m. 164°. *p*-$O_2NC_6H_4OPh$, m. 61°; NH_2 deriv., m. 84°; Ac deriv., m. 131°; nitration gives *p-acetylamino-m-nitrodiphenyl ether*, yellow, m. 104°; reduction gives the *m-NH_2 deriv.*, m. 124°; di-NH_2 deriv., m. 66°. *p-Amino-m-nitrodiphenyl ether*, red-orange, m. 47–8°, then solidifies and m. 81°; the reduction product is the di-NH_2 deriv., m. 66°; HCl salt, m. 216°; 3,3-dinitrobenzil gives *?,?-di-(p-nitrophenyl)-6-phenoxyquinoxaline*, light yellow, m. 195–6°. *p*-$ClC_6H_4NO_2$ and *p*-HOC_6H_4OPh with Cu and KOH at 150° for 5 hrs. give *p-phenoxy-p'-nitrodiphenyl ether*, yellow, m. 94°; *p-NH_2 deriv.*, m. 84°; *Ac deriv.*, m. 148°; nitration gives *p-phenoxy p'-acetamido-m'-nitrodiphenyl ether*, m. 124°; sapon. and reduction give *p-phenoxy m',p'-diaminodiphenyl ether*, m. 95°. *p*-$MeOC_6H_4OH$ and *p*-$ClC_6H_4NO_2$ give *p-methoxy-p'-nitrophenyl ether*, yellow, m. 111–2°; *p'-NH_2 deriv.*, m. 81–2°; *HCl salt*, m. 212°; *sulfate*, m. 220°; *Ac deriv.*, m. 131°; nitration gives the *m'-nitro deriv.*, m. 106°; *p-methoxy-m'-nitro-p'-aminodiphenyl ether*, m. 76–7°; *m',p'-di-NH_2 deriv.*, m. 105°. *p-Di-(nitrophenyl)dioxydiphenyl ether*, m. 136°; *di-NH_2 deriv.*, m. 109°; *di-Ac deriv.*, m. 265–6°. C. J. West

Diphenyl ether series. II. Preparation and structure of some sulfonic acids and related derivatives. C. M. Suter. *J. Am. Chem. Soc.* **53**, 1112–6(1931); cf *C. A.* **23**, 4460.—Bromination of Ba phenoxybenzene-4,4'-disulfonate and treatment of the ppt. with Na_2CO_3 soln. gives 57% of the *Na 4-bromophenoxybenzene-4'-sulfonate, p-toluidine salt*, m. 245–7°. Further bromination of the Na salt gives 84% of (4-$BrC_6H_4)_2O$. Ph_2O and Ac_2O, shaken with 95% H_2SO_4 and heated 1 hr. on the H_2O bath, give 93% of the mono-SO_3H acid (cf. Quilico, *C. A.* **22**, 1765); *p-toluidine salt*, m. 221–2°; bromination of the Na salt gives (4-$BrC_6H_4)_2O$; fusion of the Na salt with NaOH gives little or no 4-HOC_6H_4OPh. With PCl_5, heating 10 hrs. at 170–80° gives 54% of *4-phenoxybenzenesulfonyl chloride*, b_{12} 205.7°, m. 45.6°; amide, m. 128.9°; *anilide*, m. 86–8°. 4-BrC_6H_4OPh and 95% H_2SO_4 give a mono-sulfonate; $ClSO_3H$ gives *4-bromophenoxybenzene-4'-sulfonyl chloride*, m. 81.2°, also obtained in 91% yield by bromination of 4-$PhOC_6H_4SO_2Cl$; *amide*, m. 131.2°; *anilide*, m. 108–9°. *Phenoxybenzene-4,4'-disulfonyl chloride*, m. 128–9°; *diamide*, m. 158.6°. Reduction of the sulfonyl chloride with Na_2SO_3 and Na_2CO_3 gives *4-phenoxybenzenesulfinic acid*, m. 100.1°, which drops to 91–3° in 48 hrs. Reduction of the chloride with Zn and H_2SO_4 gives 60% of *4-thioldiphenyl ether*, b_{20} 178–80°, m. 21–2°; oxidation of the Na salt with air or with I in EtOH gives the disulfide, m. 47–8°. C. J. West

3,5-Dimethoxyaniline. Reinhard Seka and Walter Fuchs. *Monatsh.* **57**, 63–70(1931).—3,5-$(MeO)_2C_6H_3CO_2Me$ (I), m. 43°, and liquid NH_3 in a bomb tube at room temp. for 4 weeks give 92% of the *amide*, m. 148–9°, which may also be prepd from the acid chloride and NH_3; the Hoffmann degradation gives about 52% of *3,5-dimethoxyaniline*, b_{12} 177°, m. 46°; *HCl salt*, m. 210°; *chloroplatinate*, golden yellow, decomps. 223°; *picrate*, yellow, decomps. 167–70°; *Bz deriv.*, m. 139°; *anisoyl deriv.*, m. 119–20°. I and $N_2H_4 \cdot H_2O$, boiled 8 hrs., give 50% of the *hydrazide*, m. 168.5° (*HCl salt*, m., 210°); the azide, m. 50–1°, decomps. about 70° and with H_2SO_4 gives $(MeO)_2$-$C_6H_3CO_2H$; *urethan*, m. 43.5°. C. J. West

The behavior of *p*-acetophenetide toward chlorine and bromine. E. Burěš and J. Kovařovičová. *Časopis Českoslov. Lékárnictva* **10**, 197–202, 233–9(1930).—Chlorination of *p*-acetophenetide (I) in glacial AcOH at ordinary temp. and pressure gave 2,3,5,6-tetrachloro-*p*-acetophenetide (II), m. 226°, while bromination of I resulted in 3,5-di

bromo-*p*-acetophenetide (III), m. 175°. The entrance of the halogens caused an increase in stability, and a decrease in basicity and in ease of replacement of NH_2. Sapon. of II gave 2,3,5,6-tetrachloro-*p*-phenetide, m. 96°, from which the following *ethoxybenzenes* were prepd.: 2,3,5,6-tetrachloro, m. 56°; 2,3,4,5,6-penta-Cl, m. 75°; 2,3,5,6-tetrachloro-4-bromo, m. 81°; 2,3,5,6-tetrachloro-4-iodo, m. 79°; and 2,3,5,6-tetrachloro-*p*-quinone. Sapon. of III yielded 3,5-dibromo-*p*-phenetide (IV), m. 54°, the constitution of which was detd. by conversion to 3,5-dibromophenetole (V), b. 267°. Attempts to replace the NH_2 group in IV by OH or CN were unsuccessful, but the following *3,5-dibromoethoxybenzenes* were prepd.: Me_2N, m. 84°; BzNH, m. 159°; EtNH, m. 91°; Ac_2N, m. 108°; 4-Br m. 72°; 4-I, m. 99°; 4-Cl, m. 42–4°; and the picrate of IV, m. 145°. Nitration of III yielded 3-bromo-5-nitro-*p*-phenetide, m. 108°. Nitration of V gave 3,5-dibromo-1-ethoxy-4-nitrobenzene, m. 128°, which on reduction yielded IV. 3,4,5-Tribromo-1-ethoxy-2-nitrobenzene, m. 52–3°, was prepd. WILLIAM J. HUSA

Dehydration with potassium hydroxide of the ethylol group adjoining the benzene nucleus. III. Dehydration of the α,α′-alkylarylethanols. SEBASTIEN SABETAY. *Bull. soc. chim.* [4], **47**, 614–20(1930); cf. *C. A.* **24**, 1099.—In the distn. of alcs. of the phenylethyl alc. type over anhyd. KOH the secondary and tertiary alcs. are much more stable than the primary ones that easily form the corresponding unsatd. hydrocarbon. S. shows that of *hydratropic alc.*, $PhCHMeCH_2OH$ (I), and *methylbenzylcarbinol*, $PhCH_2CHMeOH$ (II), only I is dehydrated, to *α-methylstyrene*, $PhCMe:CH_2$ (III), by anhyd. KOH while *dehydration with "porosite"* (Ramart-Lucas and Amagat, *C. A.* **22**, 1582, and Fourneau, *C. A.* **16**, 2495) forms a mixt. of III and PhCH:CHMe. By heating 10 g. of I over 5–7 g. anhyd. KOH 2 layers form, the upper one of which is distd. off, extd. with Et_2O, dried and rectified, finally over Na. III b_{744} 159–60°, n_D^{22} 1.5350, d_{22}^{22} 0.9065, mol. refraction 40.56. It tends less to polymerization than styrene and forms a liquid *dibromide*. The identity of III was established by comparing it with III prepd. from $PhMe_2COH$ according to Staudinger and Breusch (*C. A.* **23**, 3213) as well as with "porosite" (cf. references above). *α-Ethylstyrene*, $PhEtC:CH_2$ (IV), was similarly prepd. by the action of anhyd. KOH on $PhEtCHCH_2OH$. IV b_{748} 177–80°, n_D^{22} 1.5262. Its *dibromide* seems to be liquid. Dehydration of II under the same conditions yields only traces of PhCH:CHMe. G. TOENNIES

New method of synthesis of phenylpropargyl alcohol and its homologs substituted in the ring. L. BERT. *Compt. rend.* **191**, 493–5(1930).—Instead of condensing PhC≡CH with HCHO, which will give very poor yields, B. prepd. PhC≡CCH$_2$OH in the following way (the figures under the arrows indicate the % yield obtained):

$$PhBr \xrightarrow[94]{Mg + (C_2H_5)_2O} PhMgBr \xrightarrow[100]{CH_2ClCH.CHCl} PhCH_2CH.CHCl \xrightarrow[84]{KOH\text{-}BuOH}$$

$$PhCH:CHCH_2OBu \xrightarrow[83]{HCl} PhCH:CHCH_2Cl \xrightarrow[60]{AcONa} PhCH\,CHCH_2Ac \xrightarrow[100]{Br} PhCH\text{-}$$

$$BrCHBrCH_2OAc \xrightarrow[66]{KOH} PhC:CCH_2OH.$$

The com. cinnamyl acetate, which is employed in perfumery, can be used as a starting material. F. R. GREENBAUM

Reduction of Schiff bases. L. ZECHMEISTER AND J. TRUKA. *Ber.* **63B**, 2883-4 (1930).—Mg in MeOH can be used advantageously for the reduction of the -CH:N- group in Schiff bases to $-CH_2NH-$. The reaction takes place in a neutral soln. and even when the product is decompd. with H_2O there is no marked alky. The base is dissolved in almost anhyd. MeOH, an at least 5 fold excess of Mg ribbon is added (the reaction being regulated by cooling or heating, as needed), then the MeOH is distd. off, the residue decompd. with ice H_2O and the $Mg(OH)_2$ dissolved out with 30–50% AcOH. The following amines were obtained in 70–90% yield in this way: $PhCH_2NHPh$, m. 37–8°; *p*-$MeOC_6H_4CH_2NHPh$, m. 64.5°; *o*-$HOC_6H_4CH_2NHPh$, m. 108°; $PhCH_2CH_2CH_2NHPh$, m. 193–5°; 3,4-$CH_2O_2C_6H_3CH_2NHPh$, m. 78°; *p*-$Me_2NC_6H_4CH_2NHPh$, m. 62°; *p*-$MeC_6H_4NHCH_2Ph$, m. 318–20°; α-$C_{10}H_7NHCH_2Ph$, m. 67°; α-$C_{10}H_7NHCH_2C_6H_4OMe(p)$, m. 80°; β-$C_{10}H_7NHCH_2Ph$, m. 68°; β-$C_{10}H_7NHCH_2C_6H_4OMe(p)$, m. 104.5°. C. A. R.

Acyl derivatives of *o*-aminophenol. VI. C. B. POLLARD AND R. E. NELSON. *J. Am. Chem. Soc.* **53**, 996–1001(1931); cf. *C. A.* **23**, 4940.—A study of the diacyl derivs. of *o*-$H_2NC_6H_4OH$, when 1 of the acyl groups was always the $PhCH_2CO$ radical,

is reported. When both acylating agents were of the type ClCOR, isomeric diacyls were obtained depending on the order of the introduction of the acyl groups. In 5 cases out of 8 complete rearrangement occurred during sapon., 1 case showed partial rearrangement and in 2 cases rearrangement did not occur. Apparently relative acidity and wt. are not the controlling factors in this type of rearrangement. When 1 of the acylating agents was an alkyl chlorocarbonate, the same diacyl deriv. was obtained regardless of the order of introduction of the groups. *o-Phenylacetylaminophenol* (I), m. 149–50° (60% yield); *o-butyrylamino deriv.*, m. 80–1° (58% yield); *o-(m-bromobenzoylamino) deriv.*, m. 180° (60% yield); *m-Cl isomer*, m. 156–8° (52% yield). I and AcCl with a drop of H_2SO_4 give 60% of the *acetate*, m. 101–2°; *o*-$AcNHC_6H_4OH$ and $PhCH_2COCl$ give 45% of *o-acetylaminophenyl phenylacetate*, m. 99–100°; sapon. of either gives $PhCH_2CONHC_6H_4OH$, showing that rearrangement occurred in the second case. *o-Phenylacetylaminophenyl propionate* (II), from I and EtCOCl, m. 98–9° (40% yield); *butyrate* (III), m. 91–2° (40% yield); *valerate* (IV), m. 80–2° (50% yield); *isovalerate* (V), m. 87–8° (50% yield); *chloroacetate* (VI), m. 106–7° (50% yield); *benzoate* (VII), m. 110–1° (60% yield); *m-chlorobenzoate* (VIII), m. 146–8° (65% yield). *o-Propionylaminophenyl phenylacetate*, m. 71–2° (35% yield); sapon. of this or of II gives $PhCH_2CONHC_6H_4OH$ (IX); the *o-butyrylamino deriv.*, m. 46–8° (40% yield), gives $PrCONHC_6H_4OH$ on sapon., while the isomeric III gives IX; the *o-valerylamino deriv.*, m. 71–2° (40% yield), gives $BuCONHC_6H_4OH$ (X) on sapon., while the isomeric IV gives 65% IX and 35% X; *o-isovalerylamino deriv.*, m. 56–7° (55% yield), gives iso-$BuCONHC_6H_4OH$, as does V, on sapon.; *o-chloroacetylamino deriv.*, m. 113–4° (55% yield), or VI yields IX on saponification; *o-benzoylamino deriv.*, m. 108–9° (75% yield), yields $BzNHC_6H_4OH$ on hydrolysis, while the isomeric VII gives IX; *o-(m-chlorobenzoylamino) deriv.*, m. 150–2° (55% yield), or VIII give on hydrolysis $ClC_6H_4CONHC_6H_4OH$; *o-(m-bromobenzoylamino) deriv.*, m. 157–9° (55% yield), gives the corresponding Br deriv. on hydrolysis. The *phenylacetate of Me o-hydroxycarbanilate*, m. 105–6° (60% yield), yields on hydrolysis 50% each of IX and $MeOOCNHC_6H_4OH$; the *Et deriv.*, m. 62–3° (40% yield), gives $EtOOCNHC_6H_4OH$; the *iso-Bu deriv.*, m. 72–3° (53% yield), gives the iso-Bu deriv. C. J. West

Reduction potentials of some higher benzologs of the quinones. Louis F. Fieser and Emma M. Dietz. *J. Am. Chem. Soc.* **53**, 1128–33(1931).—A potentiometric study of the benzologs of anthraquinone and phenanthrenequinone leads to the following conclusions: The potentials of the benz- and dibenzanthraquinones lend support to the *o*-quinonoid theory of the structure of anthracene. Hydroxychrysenequinone constitutes an exception to the rule that when a quinone can exist in 2 forms, the 1 of lower potential will predominate. The following values for the reduction potential at 25° (E_0 (av.) in v.) are reported: 1,2-benzanthraquinone, 0.228; 1,2,7,8-dibenzanthraquinone, 0.264; 1,2,5,6-dibenzanthraquinone, 0.268; (1,2)*Bz*-3-metho-1,2,5,6-dibenzanthraquinone, 0.257; 5,6-chrysenequinone, 0.465; 6,12-chrysenequinone, 0.392; 12-hydroxy-5,6-chrysenequinone, 0.391; 12-EtO deriv., 0.418; 1,2-benz-3,5-anthraquinone, 0.430; picenequinone, 0.474. C. J. West

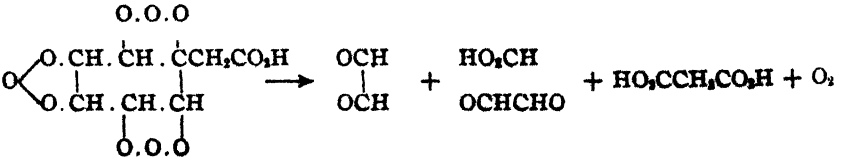
Configurational relationships of phenylated carbinols. III. P. A. Levene and A. Walti. *J. Biol. Chem.* **90**, 81–8(1931); cf. *C. A.* **24**, 4008.—A direct chem. method is found for the correlation of the configuration of $Me(PhCH_2)CHOH$ with *sec*-aliphatic alcs. The method is based on the condensation of optically active ethylenic oxides with aliphatic or aromatic radicals by the Grignard reaction. Condensation of *d*-$MeCH.CH_2.O$ (I) with C_5H_7MgBr gave *l*-$MeCH(OH)C_6H_9$, $[\alpha]_D^{25}$ —1.75° (without solvent), and its *α-naphthylurethan* gave $[\alpha]_D^{25}$ —4.28° (in abs. alc.). PhMgBr and I gave *l*-$Me(PhCH_2)CHOH$, $[\alpha]_D^{25}$ —19.8° (without solvent); *α-naphthylurethan*, $[\alpha]_D^{25}$ —31.6°. The latter carbinol was oxidized to the corresponding ketone which was then identified by the *semicarbazone*, m. 188°. L. and W. conclude that the direction of rotation is detd. by the position of the heavier group, provided the Ph group is not less than 1 C atom from the asym. C atom. H. W. Leahy

Beckmann rearrangement. IV. Unsaturated ketoximes. Karl v. Auwers and Maria Seyfried. *Ann.* **484**, 178–211(1930); cf. *C. A.* **19**, 1405; **23**, 4701.—PhCH:CHBz (I) with NH_2OH in alk. soln. gives 3,5-diphenylisoxazoline, m. 75°, and a mixt. of alkali-sol. hydroxyaminoöximes. The oxime (II) of I, m. 115–6°, was prepd. by the use of $NH_2OH.HCl$; this was unchanged by boiling with 2 *N* NaOH for 10 hrs. The Beckmann rearrangement gives PhCH:CHCONHPh (cf. Henrich, *C. A.* **1**, 1411). II yields a dibromide, m. 156°, which splits off HBr when heated above its m. p., giving 3,5-diphenylisoxazole (III). Beckmann rearrangement gives a *dibromohydrocinnamic*

anilide, m. 179°. PhCHBrCHBrBz could not be transformed into the oxime. PhCH:CBrBz yields an oxime, m. 151° (*C. A.* **23**, 4701), which gives **III** with EtOH-KOH. The Beckmann rearrangement product, probably PhCH:CBrCONHPh, was obtained only as a brown smeary product. *p*-$MeOC_6H_4COCH$:CHPh (**IV**) and $PhNHNH_2$ in AcOH give *1,5-diphenyl-3-p-anisylpyrazoline*, m. 140.5–1.5°; the concd. H_2SO_4 soln. becomes blue-violet on addn. of $FeCl_3$; NH_2OH in alk. soln. gives *3-p-anisyl-5-phenylisoxazoline*, m. 104.5–5.5°, oxidized by CrO_3 in AcOH to the isoxazole (**V**), m. 121°; this is also obtained from *p*-$MeOC_6H_4COC$: CPh and $NH_2OH.HCl$, while free NH_2OH gives 3-phenyl-5-anisoylisoxazole, m. 127–8°. **IV** and $NH_2OH.HCl$ in EtOH give *benzal-p-methoxyacetophenone oxime*, m. 140–2°; *Ac deriv.*, m. 134–5°; Beckmann rearrangement gives *cinnamic p-anisidide*, m. 152–3°. *p*-$MeOC_6H_4COCBr$·CHPh, b_{13} 250–3°, with NH_2OH in NaOH gives **V**; NH_2OH HCl gives the *oxime*, m. 153°. The relative rates of decompn. of the ketone and oxime by EtOH-KOH are: 10 min., 17, 86%; 20 min., 50, 95%; 30 min., 66, 95%; 15 hrs., 100, 95%. Beckmann rearrangement gives a brown smear, from which *p*-$MeOC_6H_4CO_2H$ was isolated after hydrolysis. *β-Bromobenzal-p-methoxyacetophenone*, from PhC : $CCOC_6H_4OMe$, yellow, m. 65–6°; NH_2OH and alkali give **V**; $NH_2OH.HCl$ gives 50% of the oxime (**VI**), m. 115–6°. The relative rates of decompn. of the ketone and oxime by alkali are: 10 min., 10, 11%; 20 min., 95, 51%; 30 min., —, 68%; 15 hrs., 95, 85%. The relative rates of decompn. of the α- and β-bromo oximes with 2% NaOH are: 2 min., 10, 11%; 7 min., 45, 14%; 12 min., 70, 16.5%; 17 min., 95, 16.5%. The Beckmann rearrangement of **VI** gives *β-bromocinnamic p-anisidide*, m. 144°. *Benzal-p-ethoxyacetophenone dibromide*, m. 151–2°. **V. Substituted cinnamaldoximes and cinnamonitriles.** *Ibid* 212–35.—*cis*-PhCH:CBrCHO (**I**) is oxidized to *trans*-PhCH:$CBrCO_2H$ by alk. Ag_2O or by O_2 in $CHCl_3$. The oxime (**II**) of **I**, m. 144°, results in acid, alk. or neutral medium; warming with EtOH-H_2O-KOH gives PhC : CCH:NOH, m. 108°; Ac deriv. of **II**, m. 81–2°; heating **II** with Ac_2O gives *cis*-PhCH:CBrCN (**III**), b_9 138–40°, $d_4^{19.1}$ 1.4624, $n^{19.1}$ 1.61984, 1.62983, 1.65669 for α, He and β; this also results from the acid amide and $POCl_3$ at 70–2°. *Dibromocinnamonitrile*, m. 92–3°, also gives **III** with EtOH-KOH. **II** and PCl_5 in dry Et_2O, allowed to stand 10–24 hrs., give the *trans-isomer* (**IV**), b_{12} 148–50°, m. 33–5°, $d_4^{58.5}$ 1.4263, $n^{58.5}$ 1.60386, 1.61348, 1.63904 for α, He and β; **IV** was also obtained from the *trans*-acid amide, m. 120–1°, and $POCl_3$ at 70–2°. Attempts to change **III** to **IV** or **IV** to **III** failed. The relative rates of reaction of **III** and **IV** with EtOH-KOH are: 2 min., 42.3, 78% decompose; 10 min., 99.6, 42.6%. **III** or **IV** and 10% EtOH-KOH give *β-ethoxycinnamonitrile*, b_{10} 146–8°, $d_4^{18.4}$ 1.0601, $n^{18.4}$ 1.55988, 1.56718, 1.58641, 1.60482 for α, He, β and γ. Addn. of EtOH to PhC : CCN gives an *isomeric nitrile*, b_{11} 163–5°, d_4^{17} 1.0543, 1.54569, 1.55169, 1.56756 for α, He and β. Both forms give $BzCH_2CN$ with dil. H_2SO_4 and show little difference in their reaction with Br in CS_2. PhC : CCHO and HBr in AcOH give *β-bromocinnamaldehyde*, b_{12} 144–6°, d_4^{20} 1.492, $d_4^{18.85}$ 1.4937, $n^{18.85}$ 1.62865, 1.63884, 1.66649 for α, He and β; it slowly decomposes in the air, giving off HBr. Heating with 1.1 mols. AcOK in abs. EtOH for 7 hrs. splits off 24.4% of the Br; *oxime*, m. 81°, sepd. by means of the Na salt into 2 isomers, m. 63–6° and 103° (*Ac deriv.*, m. 68–9°). The relative rates of decompn. of the aldehyde and oxime by 5% EtOH-KOH are: 5 min., 30.5, 2.2%; 10 min., 77.2, 4.4%. C. J. WEST

Reduction of the mixture of aldehyde or ketone with nitrite. II. A. OGATA AND S. HIRANO. *J. Pharm. Soc. Japan* **50**, 1141–52 (1930); German abstr. 147–8; cf. *C. A.* **24**, 4758.—Reduction of the mixt. of equiv. quantities of BzH and $NaNO_2$ in alc. AcOH or HCO_2H with excess Zn dust gave $PhCH_2NH_2$, $(PhCH_2)_2NH$, *α,β-diphenyl-α-hydroxy-β-benzylaminoethane* (**I**) and NH_3 as end-product. **I**, $C_{21}H_{21}ON$, m. 151°, sol. in hot alc., but insol. in H_2O. HCl salt, m. 226–8°, *Bz deriv.*, m. 135–6°. The formation of *benzylamine* is due to the formation of an intermediate compd., *benzaldoxime*, followed by reduction, while *dibenzylamine* is due to the reaction between $PhCH_2NH_2$ and unreacted BzH, followed by reduction. F. I. NAKAMURA

Isomerization of the hydroxy aldehydes. IV. Transformation of benzylbromoacetaldehyde and benzylglycolaldehyde. S. DANILOV AND E. VENUS-DANILOVA. *Ber.* **63B**, 2765–75; *J. Russ. Phys.-Chem. Soc.* **62**, 1697–1711(1930); cf. *C. A.* **24**, 1093.—*Benzylbromoacetaldehyde* (**I**), from $PhCH_2CH_2CHO$ and Br in CS_2, is an unstable oil readily resinifying and polymerizing on standing, but it yields a cryst. *monohydrate*, m. 87.5–8°, which permitted of studying the conversion of **I** into *benzylglycolaldehyde* (**II**) and the acid (**III**). Heated with H_2O and freshly pptd. $BaCO_3$ **I** gives **II** in quite good yields, together with 4% $PhCH_2CH_2CO_2H$ (**IV**). With Ag_2O are obtained 20% **II**, 9.4% **III**, 5.6% of a condensation product (**V**) of **I** and 31% **IV**. PbO_2 yields chiefly halogen-contg. condensation products of **I** and 22.6% **IV**. The structure of **II** is es-



tablished by its prepn., its derivs. and its oxidation products; $KMnO_4$ in aq. C_5H_5N gives $PhCH_2CHO$, BzOH and III. Its isomerization into the HO ketone is accompanied by the formation of a diketone: $PhCH_2CH(OH)CHO$ (II) ⟶ $PhCH(OH)COMe$ (VI) + PhCOCOMe (VII). II, b_4 120–1°, m. 51.5–2°, reacts with NH_3-$AgNO_3$, fuchsin-SO_2 and Fehling soln., mol. wt. in freezing C_6H_6 143.7; *oxime*, m. 123°; *semicarbazone*, m. 136.5°; *phenylosazone*, yellow, m. 137°; *benzoate*, m. 70°, mol. wt. in freezing C_6H_6 252.6. III, m. 97.5°, mol. wt. in freezing C_6H_6 150. VII, b_{13} 113–5°; dioxime, m. 238–9°. VI, b_{13} 130–2°, mol. wt. in freezing C_6H_6 155–61; semicarbazone, m. 194°. With $PhMgBr$ VI yields $PhMeC(OH)CH(OH)Ph$, m. 103°, gives with concd. H_2SO_4 a deep red color destroyed by H_2O and is oxidized by CrO_3-AcOH to PhCOMe and BzOH. C. A. R.

New *p*-bromophenacyl esters. S. G. Powell. *J. Am. Chem. Soc.* **53**, 1172 (1931).—The following *p-bromophenacyl esters* were prepd.: *trimethylacetate*, m. 76.5°; *isocaproate*, m. 77.3°; *enanthate*, m. 69.2°; *isoheptylate*, m. 75.5°; *pelargonate*, m. 63.5°. C. J. West

Oximes of α,β-unsaturated ketones and the Beckmann rearrangement. A. H. Blatt. *J. Am. Chem. Soc.* **53**, 1133–41(1931).—Certain α,β-unsatd. ketones, when treated with $NH_2OH.HCl$, yield oximes of the general configuration $RCH{:}CHCR'{:}NOH$. These oximes undergo a *trans*-shift in the Beckmann rearrangement and when dissolved in concd. H_2SO_4 rearrange in a different manner to yield the isomeric isoxazolines $RCH.CH_2.CR'{:}NO$. The so-called stable oximes of these α,β-unsatd. ketones are in reality isoxazolines and are formed through a process which does not involve either the true oxime as an intermediate or the simple 1,4-addn. of NH_2OH to the ketone. *Benzal-o-chloroacetophenone oxime* m. 110–24° when heated at the rate of 2° per min., even though the oxime was pure; PCl_5 in excess in abs. Et_2O gives *cinnamic o-chloroanilide*, m. 136–7°, also obtained from the acid and *o*-$ClC_6H_4NH_2$. Boiling the oxime with MeOH-KOH for 5.5 hrs. removes only 2.3% of the Cl. *Benzal-p-bromoacetophenone oxime* m. 138–50°; there was no evidence of isoxazoline formation with EtOH-KOH or NH_2OH; PCl_5 gives the *p-bromoanilide of cinnamic acid*, m. 191°; bromination of the oxime gives a *di-Br deriv.*, m. 155° (decompn.); with EtOH-KOH it eliminates HBr, giving *3-p-bromophenyl-5-phenylisoxazole*, m. 178–9°; this also results in 50% yield by heating the oxime at 150° or by heating in glacial AcOH; it was also obtained from $PhCHBrCHBrCOC_6H_4Br$ and $NH_2OH.HCl$; the *isoxazoline*, m. 138–9°, results from the oxime and concd. H_2SO_4 or from the ketone, $NH_2OH.HCl$ and KOH. C. J. West

Methods of manufacturing vanillin. J. Schwyzer. *Chem.-Ztg.* **54**, 817–8, 839–40(1930).—Explicit details of the 4 practical methods for the manuf. of vanillin are given. The methods are (*a*) chlorination of PhOH, treatment with $Ba(OH)_2$ to form *o*-$C_6H_4(OH)_2$, treatment of this with *m*-$O_2NC_6H_4SO_3Na$, CH_2O and Fe filings to give 3,4-$(HO)_2C_6H_3CHO$, followed by methylation; (*b*) treatment of piperonal with PCl_5 and hydrolysis of the product to 3,4-$(HO)_2C_6H_3CHO$, followed by methylation. (*c*) sulfonation of $PhNO_2$, reduction by electrolysis or by Zn and HCl, and treatment with guaiacol, $FeSO_4$ and CH_2O, or treatment of guaiacol with MeOH, $Me_2NC_6H_4NO$ and CH_2O, or guaiacol is treated with alloxan prepd. by the action of Cl_2 on uric acid, sapon. with NaOH, treatment with SO_2, then with *p*-$Me_2NC_6H_4NH_2$, and finally with NaOH; (*d*) formation from clove oil. C. H. Peet

The action of ozone on benzoic acid and phenyl aliphatic acids. H. Rupe and H. Hirschmann. *Helv. Chim. Acta* **14**, 49–56(1931).—BzOH and phenyl aliphatic acids add on a mol. of O_3 at each of the double bonds of the benzene nucleus to form triozonides. These compds. are white camphor-like substances at low temps. and oils at room temps. They are not very stable and tend to decomp. with explosive violence at room temp. They decomp. with water to form, probably, 1 mol. O_2, 2 mols. glyoxal, 1 mol. HCO_2H and 1 mol. of a dibasic acid. The yields of these hydrolysis products are poor. The yields of the ozonides are also poor as apparently much of the phenyl aliphatic acids are completely oxidized. The triozonide of $PhCH_2CO_2H$ (I) probably decomps. with water as follows:

Ten g. of I was dissolved in 100 cc. CCl_4 and at 0–15° treated with 10–12% O_3 for 24 hrs. The white ozonide was filtered and washed with ice-cold abs. ether and decompd. with water on the water bath. The clear soln. gave 1.1 g. of $(CH{:}NNHCO\text{-}NH_2)_2$ (IV), decomps. 300°. HCO_2H was identified by its odor and the sepn. of about 0.5 g. which reduced $HgCl_2$ and HgO. $CH_2(CO_2H)_2$ was identified by formation of $PhCH.CHCH{:}C(CO_2H)_2$, m. 202–3° instead of 208° as given by Rupe (*Ber.* **37**, 3123) and by the solid acid isolated in about 0.1 g. yield, giving off CO_2 when melted. I (1.7 g.) was recovered unchanged. In 1 expt. 10 g. of $PhCH_2CH_2CO_2H$ (II) in 100 cc. CCl_4 was treated at 0–15° with 10–12% O_3 for 24 hrs. The white ozonide after decompn. with water yielded 4.2 g. of IV, 0.8 g. $(CH_2CO_2H)_2$ and only 0.1 g. of II was recovered unchanged. Ten g. of BzOH (III) in 80 cc. $CHCl_3$ and 20 cc. CCl_4 was treated at 0–15° with 10–12% O_3 for 20 hrs. III gave the best yields of ozonide but this ozonide was the least stable. One sample of 3.5 g. exploded in the desiccator. The ozonide from the above sample on decompn. with water yielded 0.62 g. IV and 0.5 g. $(CO_2H)_2$ and 5.5 g. III was recovered unchanged. III is more resistant to the action of O_3 than either I or II. ODEN E. SHEPPARD

Condensation products of phenylacetic hydrazide. REINHARD SEKA AND ST. PETER HEILPERIN. *Monatsh.* **57**, 45–51(1931).—$AcCO_2H$ and $PhCH_2CONHNH_2$ (I) in H_2O give 76.6% of the *hydrazone*, $PhCH_2CONHN{:}CMeCO_2H$, m. 168°; the mother liquor contains *diphenylacetic hydrazide* (II), $(PhCH_2CONH)_2$, m. 236–7°. With $AcCH_2CO_2Et$ and I only II is formed. Levulinic acid gives the *phenylacetic hydrazone*, m. 119°; the mother liquor contains II. Galactose likewise gives a *hydrazone*, m. 192–3° (58% yield). Ac_2 and I give a *monophenylacetic hydrazone*, m. 138°, sol. in H_2O, and a *diphenylacetic hydrazone*, $C_{20}H_{22}O_2N_4$, decomps. 254°. Benzil gives a *diphenylacetic hydrazone*, $C_{30}H_{26}O_2N_4$, m. 198–9°. C. J. WEST

Several new 4′-sulfo-*o*-benzoylbenzoic acid derivatives and the corresponding anthraquinone compounds. IVAN GUBELMANN, H. J. WEILAND AND O. STALLMANN. *J. Am. Chem. Soc.* **53**, 1033–6(1931).—2-$HO_2CC_6H_4COC_6H_4SO_3Na$-*p*, nitrated with a mixed acid (100 g. mixed acid contg. 70% HNO_3, 22% H_2SO_4 and 8% H_2O with 480 parts of 25% oleum) in 100% H_2SO_4, the acid being added over 6–8 hrs. at 15–20° and the reaction then heated at 35° for 3 hrs., gives the *5′-NO_2 deriv.*; 100 g. of the free acid, heated with 25% oleum at 150°, give 80 g. of *2-nitroanthraquinone-7-sulfonic acid*; with $NaClO_3$ in dil. HCl there results quant. the *7-Cl deriv.*, light yellow, m. 251–2°; reduction gives nearly quantitatively the *2-NH_2 deriv.*, light orange, m. 302–3°. 5,2-$H_2N(p\text{-}HO_3SC_6H_4CO)C_6H_3CO_2H$, by reduction of the above NO_2 deriv., gives with oleum 2,7-$H_2NC_6H_3(CO)_2C_6H_3SO_3H$, which may be transformed into the 2,7-di-NH_2 deriv. by NH_4OH and As_2O_3 at 180°. Further proof is offered by the m. p. of the corresponding di-HO deriv. and its di-Ac deriv. C. J. WEST

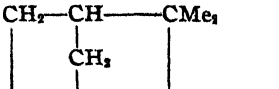
Some new water-soluble organomercury compounds. JOHN H. WALDO. *J. Am. Chem. Soc.* **53**, 992–6(1931).—MeHgI and *o*-$HSC_6H_4CO_2H$ in EtOH-NaOH give 80–5% of *methylmercurithiosalicylic acid*, m. 174° (all m. ps. cor.); *Et deriv.*, m. 111°; *iso-Am deriv.*, m. 78°; *p-ethylmercurimercaptobenzoic acid* does not m. 250°; the *sulfonic acid* was also prepd. The following compds. were prepd. but analyzed only for Hg: *phenylmercurithiosalicylic acid*, m. 228.5° (decompn.); *benzyl deriv.*, m. 144.5° (decompn.); *α-ethylmercurimercaptobutyric acid*, m. 76°; *p-ethylmercurimercaptophenylacetic acid*, m. 116.7°; *p-ethylmercurimercaptobenzenesulfonic acid*, m. above 300°. These compds. are sol. in $NaHCO_3$ and form with the alkali metals sol. salts whose solns. are in general stable and do not give an immediate ppt. of HgS with $(NH_4)_2S$. Therapeutic data are given: the alkaryl derivs. are less toxic than the aryl; the salts of CO_2H derivs. are less toxic than the SO_3H derivs.; some decrease in the therapeutic index is produced by a change from the *o*- to the *p*-position on the C_6H_6 ring and by alkyl instead of alkaryl derivs. The aryl compds. are decidedly less stable, either in soln. or dry, than the alkaryl compds. C. J. WEST

Pyromellitic acid. Benzodiketohydrindene and benzodipyridazine derivatives. REINHARD SEKA, HANS SEDLATSCHEK AND HEINRICH PREISSECKER. *Monatsh.* **57**, 86–96(1931).—$O(CO)_2C_6H_2(CO)_2O$ (I) and quinaldine, heated at 250° until the mass is solid, give the *condensation product* (II), $C_{30}H_{16}O_4N_2$, dark reddish brown, decomps. 265°, insol. in EtOH, and the yellow-brown, EtOH-sol. *compd.*, $C_{20}H_{11}O_4N$, decomps. about 125°. Sulfonation of II with 50% oleum at 170° gives a product similar to quinoline yellow, which dyes wool and silk a pure yellow. I and α-$C_{10}H_7NH_2$ give *pyromellitic dinaphthylimide*, m. 431°. $N_2H_4.H_2O$ (4 mols.) gives the *dihydrazide*, light yellow, decomps. about 450°; its *tetra-Ac deriv.* m. 235–8°. 1,4,2,5-$Bz_2C_6H_2$-$(CO_2H)_2$ and 10 mols. $N_2H_4.H_2O$ in abs. EtOH, heated 24 hrs. at 120°, give 90% of *1,6-diphenyl-4,9-dihydroxybenzodipyridazine*, carbonizes at 445°; 1,5,2,4-$Bz_2C_6H_2$-

$(CO_2H)_2$ and 6 mols. $N_2H_4.H_2O$ give the *1,9-diphenyl-4,6-dihydroxy deriv.*, decomps. 430°. $(MeC_6H_4CO)_2C_6H_2(CO_2H)_2$ and $N_2H_4.H_2O$ give the *1,9-dixylyl-4,6-dihydroxy deriv.*, carbonizes at a high temp. 2-Benzoylanthraquinone-3-carboxylic acid and 3.8 mols. $N_2H_4.H_2O$ in abs. EtOH, heated 9 hrs. at 120°, give the *hydrazide*, light yellow, decomps. 374°. 1,2,4,5-$C_6H_2(COCl)_4$ and MeONa in C_6H_6 give 88% of *tetra-Me pyromellitate*, m. 138°; the *tetra-Ph ester*, m. 179.5°, results in 24% yields.

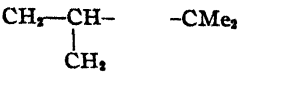
C. J. WEST

The influence of impurities on some physical and crystallographic properties of hemimellitic acid. V. AGAFONOV. *Compt. rend.* **192**, 99–101(1931); cf. *Compt. rend.* **124**, 855(1897).—After 2 recrystns. of hemimellitic acid, $C_6H_3(CO_2H)_3$ (I), there can still be isolated small quantities of Ca hemimellitate (II) and another compd. (III), both of which are monoclinic and have smaller birefringence than I. The refractive indices for the D line are: I, n_p 1.4316, n_m 1.6358, n_g (calcd.) 1.6744; II, n_p 1.52, n_g 1.68; III, n_p 1.515, n_g 1.63. The pure I is triclinic and the axial ratios are 1.705:1:0.6185. The ds. and solubilities at 20° of the 3 compds., and a full description of the crystals of I, are given. Microscopic observation of the process of crystn. shows that small quantities of II and III are included within the crystals of I and are probably the cause of its polychroism in the ultra-violet, since according to A., polychroism is always due to the presence of impurities or polymers in regular orientation.



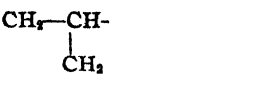
K. V. THIN

Sclareol and its derivatives. MAURICE-MARIE JANOT. *Compt. rend.* **191**, (1930).—Sclareol (I) obtained from the essential oil of *Salvia sclarea* L. appea be $C_{17}H_{30}O_2$. It b_3 188–9° and b_{19} 218–22° to give by condensation a solid pro which is transformed slowly at room temp. and instantaneously at 45° into crystals, m. 104–5°. I is not sapond. by alc. KOH or by KOH in $PhCH_2OH$. Heated to near its m. p. it loses 45% of its wt. in 72 hrs. It gives no test for MeO, is acetylated with difficulty, giving only a 50% yield, and is benzoylated in the presence of pyridine with difficulty. It gives CO_2 and $CO(NHPh)_2$ when heated to 150° with OCNPh. Alc. I gives a violet color with saccharose and furfural, and a garnet-red color with PhCH:CHCHO, vanillin and piperonal. (Ekkert, *C. A.* **22**, 2384). In CS_2 contg. Ag_2CO_3 I adds Br to give 3 compds.: (1) a cryst. deriv., m. 122–4°, contg. 35.33% Br, and (2) and (3), hexagonal crystals m. 134–5° and 140–3°, resp. I adds H in alc. in the presence of colloidal Pd to give 98% of a cryst. deriv. m. 114–5°, mol. wt. 270. Oxidation with $KMnO_4$ in HOAc gives sclareolic acid besides other compds. and oxidation with H_2CrO_4 gives a non-acidic compd. m. 124–5°. Alc. I shows no absorption in the ultra-violet. The sp. rotatory data of the various compds. are given.



C. J. PEDERSEN

Camphor and terpenes. VI. So-called camphor cyanohydrins. J. HOUBEN AND E. PFANKUCH. *Ann.* **483**, 271–304(1930); cf. *C. A.* **21**, 1808.—H. previously showed that camphorimine easily adds HCN, giving a camphor cyanohydrin; Passerini (*C. A.* **20**, 595) claims to have isolated the same compd. from pernitrosocamphor and KCN. A re-examn. of P.'s compd. (I) shows that it is camphene-1-carboxamide. From I is prepd. a Ag salt and a Me ester, $C_{12}H_{21}NO_3$, m. 102°. The *dl*-, *d*- and *l*-forms of I may be obtained by starting with the proper camphor; thus, the *d*-form prepd. from the pernitrosocamphor from *d*-camphor, HCN and Et_3N in Et_2O has $[\alpha]_D$ 78.5°. Sapon. of I with alkali gives camphene-1-carboxylic acid; the *d*-form has $[\alpha]_D^{19}$ 95.5°. When the *d*- and *l*-forms are mixed in petroleum ether, the *dl*-form seps., showing that the 2 acids differ only in optical properties. O_3 oxidizes the acid to camphenilon-carboxylic acid (II) and camphenonic acid (III), m. 133–4°. II gives an *oxime*, m. 171–2°. The action of O_3 on I gives the amide of III. III with aq. alkali gives camphenecamphoric acid, the *dl*-form m. 133–4° and the *d*-form m. 142–3°. Reduction of the acid gives *dihydrocamphene-1-carboxylic acid*, m. 174–5°, $[\alpha]_D^{20}$ —16.7°. Reduction of I gives the corresponding amide, m. 189°. I and Ac_2O, boiled 2 hrs., give *d-camphene-1-carboxylic nitrile* (IV), b_{18} 108–10°, m. 38–40°, $[\alpha]_D^{18}$ 40.5°. The acid with $SOCl_2$ and NH_4OH gives I, m. 208°. The camphor cyanohydrin of H. and P. (V) is not sapond. by concd. HCl or 48% HBr; with HNO_3 it gives IV and a blue-green oil, which gives with MeOH-KOH *d*-camphene-1-carboxylic acid and a small quantity of the amide; there also results an oxynitrile, which is dehydrated by Ac_2O to IV and with EtOH-H_2O-KOH gives *3-(α,α-dimethylacetonyl)pentamethylenecarboxylic acid* (VI), b_{19} 186–8°, $[\alpha]_D^{18}$ —2.6°; *semicarbazone*, m. 200–2°. Further degradation with NaOBr gives camphenecamphoric acid (VII), m. 134–5°, identical with that obtained from III. The oxynitrile is a *camphene hydrate-1-carboxylic nitrile*. *d*-Camphene-1-carboxylic acid and HBr in AcOH give the *dl-Br hydrate*, m. 118–20° (decompn.), $[\alpha]_D^{19}$



—16.5°; dil. alkali or K_2CO_3 gives the *camphene hydrate-1-carboxylic acid*, m. 142–3°, $[\alpha]_D^{17}$ —17°; the H_2O is split off by boiling with 0.1 *N* H_2SO_4 for 15 min.; the *Me ester*, m. 59–60°, $[\alpha]_D^{19}$ —19.5°; MeOH-KOH gives VI. *d*-Camphene-2-carboxylic acid and HBr in AcOH give the *Br hydrate*, m. 165–6°; the corresponding *hydrate* m. 221°; *Me ester*, m. 61–2°, $[\alpha]_D^{18}$ 24.5°. *dl-Camphene-bromohydrate-1-carboxylic nitrile* m. 150–1°; attempts to prep. the hydrate gave only the unsatd. compd.

C. J. West

π-Camphor derivatives. II. Identity of dihydroteresantalic acid with 7-π-apocamphanecarboxylic acid. Torsten Hasselström. *J. Am. Chem. Soc.* **53**, 1097–103(1931); cf. *Ann. Acad. Fenn.* **30**, 12(1929).—The lactone of 2-hydroxy-7-π-apocamphanecarboxylic acid, with alk. $KMnO_4$, gives *ketodihydroteresantalic acid* (*2-keto-7-π-apocamphanecarboxylic acid*), m. 269–70°, $[\alpha]_D^{28}$ —55° (10% EtOH); *semicarbazone*, m. 204–5° (decompn.); heating the latter with EtONa at 170–80° for 15 hrs. gives a good yield of 7-π-apocamphanecarboxylic acid (dihydroteresantalic acid), m. 228–9° (cor.), nearly optically inactive; this is identical with the compd. obtained by complete synthesis in part I. The crude mixt. of Me chlorodihydroteresantalate, reduced with Al-Hg in moist Et_2O at room temp., and finally with Na and EtOH, gives dihydroteresantalol (π-borneol), m. 171°; oxidation with $K_2Cr_2O_7$ and H_2SO_4 gives dihydroteresantalal, whose semicarbazone m. 212–3° (decompn.); further oxidation with $KMnO_4$ in NaOH gives dihydroteresantalic acid, m. 229–30°, identical with the acid prepd. as above. The addn. of HCl to teresantalol, m. 114°, gives a liquid and a solid form of chlorodihydroteresantalol; the solid part (2-chloro-7-π-borneol) m. 125–6° (decompn.) and on reduction with Na and EtOH gives π-borneol. C. J. West

Optically active α-pinenes. F. H. Thurber and R. C. Thielke. *J. Am. Chem. Soc.* **53**, 1030–2(1931).—Details are given for the prepn. of pinene nitrosochlorides; the 3 forms, *dl*-, *d*- and *l*-, m. 115°, 89.5° and 90°, resp., and have $[\alpha]_D^{20}$ (C_6H_6) 0°, 396.2° and 366.8°; they decompose at room temp. to a brown oily mass in about 3 weeks, but are stable for a much longer time at —20°; the regenerated α-pinenes show the following properties: b_{760} 155–6°, d_{20} 0.8591, n_D^{20} 1.4663, $[\alpha]_D^{20}$ 51.14° and —51.28°. The HCl compds. m. 132° (cor.) and the active forms have $[\alpha]_D^{20}$ (1% EtOH soln.) 33.52° and —33.24°. Contrary to previous reports the *dl*-pinene yields an inactive HCl deriv. and the active pinenes yield active HCl derivs. whose rotations are equal and opposite in sign. C. J. West

Stereochemistry of derivatives of biphenyl and analogs. Francis Lions. *J. Am. Chem. Soc.* **53**, 1176–9(1931).—L. outlines certain researches in the 2- and 4-phenylpyridine and 2-phenylquinoline series, phenylpyrroles, phenylindoles and biphenyl derivs. Failure to obtain these substances in enantiomorphous forms has prevented publication; this note is offered because of the work of Adams (*C. A.* **25**, 105) in the field of phenylpyridines. C. J. West

Bistibyls. I. Tetraphenylbistibyl. Attempts to obtain tetraphenylbibismuthyl. F. F. Blicke, U. O. Oakdale and F. D. Smith. *J. Am. Chem. Soc.* **53**, 1025–9(1931).—*Diphenylstibyl iodide*, m. 68–70°, results from the chloride and NaI in Me_2CO; a PhBr soln. does not absorb O, although a mixt. with Ph_3CBr does. The iodide reacts with Cu in PhBr, giving the bistibyl but this apparently undergoes decompn. or is rendered inactive toward O by the Cu halide or by combination with unchanged Ph_2SbI. The iodide in abs. EtOH with NaH_2PO_2 gives *tetraphenylbistibyl*, m. 121–2°, which reacts instantly with I, giving Ph_2SbI; it also absorbs the calcd. amt. of O to give $(Ph_2Sb)_2O_3$. Ph_2BiI in PhBr, shaken with Ag, Hg, Zn and Cu bronze, did not give solns. which absorbed O. NaH_2PO_2 did not appear to react with an EtOH soln. at room temp., and on heating gave a black product. $(Ph_2Bi)_2$ could not be obtained. C. J. West

Action of phenol on benzoyldiphenylmethyl bromide. C. Frederick Koelsch. *J. Am. Chem. Soc.* **53**, 1147–50(1931); cf. Schuster, *C. A.* **25**, 943.—S. reported that Ph_2CBrBz and PhOH give $Ph_2C(OPh)Bz$ (I), which reacted with PhMgBr to give $Ph_2C(OPh)C(OH)Ph_2$ (II). Repetition of the reaction shows that the reaction really gives *p*-BrC_6H_4OH and Ph_2CHBz (S.'s I). Ph_2CHBz and KOH give Ph_2CH_2 and BzOK,

while Ac_2O and H_2SO_4 give $Ph_2C:C(OAc)Ph$. Ph_2CHBz and Ph[illegible] give Ph_2CHCPh_2OH, m. 232-3° (S.'s II), which decomposes with KOH to [illegible] and BzPh.

C. J. WEST

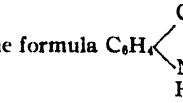
Constitution of colorless and colored triphenylmethane derivatives. T. LIPSCHITZ. *Ber.* **64B**, 161–82(1931); cf. *C. A.* **24**, 100, 1368, 4020.—In an earlier paper (Lifschitz and Girbes, *C. A.* **22**, 3855) L. has formulated his theory as to the constitution of derivs. of Ph_3CH. In the present paper he answers criticism of his theory by Hantzsch, Dilthey and others, criticizes H.'s theory as to the nature of halochromes, shows the untenability of certain of D.'s views, and develops his own theory further, adding special proofs for certain phases of it. H. has shown that the substances $Ar_3C.X$ belong to 2 optically different series, between which there is no optical transition. H. considers these series isomeric; if they are, the colorless and colored Ph_3C derivs. should have the same mol. wts. Since there is no proof of this, L. states that the assumption of isomerism has no foundation. Another defect of H.'s theory is that it cannot explain the most characteristic property of halochrome salts—their peculiar light absorption. In most of the compds. $Ar_3C.X$, the C X bond is heteropolar, Ar_3C^+X'. This may give the electrolyte $[Ar_2C...R]X'$, whose free ions may be stable or may undergo further change. Anion X′ may be solvated, or may form complex ions with suitable mols., such as metal halides. The cations may form

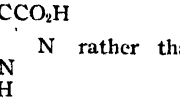
$$Ar_2C=\begin{matrix}R_1\\ \\ R\end{matrix}\Big]X' \text{ (I)},$$

the real mother substance of the halochrome carbonium

Because of their quinoid nature these can form deeply colored mol. compds., such as

$$\left[\begin{matrix}Ar_2C\\ :\\ R_2\end{matrix}\right]\begin{matrix}R^-\\ \downarrow\end{matrix}$$





which are analogous in structure to meriquinoid compds. Structure I belongs to various so-called halochrome compds. with dye-like absorption. L's theory is thus shown to explain the facts satisfactorily. Retaining a coördination no. of 4 for C, as assumed by Werner, and without using the forced deductions of H, it is possible to explain the influence of the solvent on the color of Ph_3CH derivs. The first step in the formation of the colored forms is substitution; the final step is addn. with the formation of mol. compds. of quinoid ions. Where the latter is not possible and complex formation with the compd. itself enters in, the reason lies in the nature of the medium. In the substances mentioned the chromophor which shows the visible color is the quinone C atom in the ring. Solns. of halochrome derivs. of the same triphenylcarbinol contain not the same complex, as H. thought, but different complexes with the same chromophor. With the exception of neutral perchlorates all the isolated halochromes are mol. compds, and it can easily be shown that complex formation produces the color. L.'s theory also explains satisfactorily the electrolytic behavior of Ph_3CH derivs., and is further strengthened by the results obtained in detns of the mol. wts. of such derivs.

LOUISE KELLEY

The synthesis of *N*-methylhydroxynaphthindolequinone and *N*-methylnaphthisatinquinone. ZENJIRO KITASATO AND CHUZABURO SONE. *Bull. Chem. Soc. Japan* **5**, 348–54(1930); cf. *C. A.* **22**, 1779.—To study the origin and properties of such indigoid substances as nandazurin, 1-methylhydroxynaphthazolequinone (**VIII**) has been synthesized as follows: 2,3-dibromo-α-naphthoquinone and $NaCH(CO_2Et)_2$ give bromo-α-naphthoquinonemalonic ester (**I**), 5 g. of which suspended in 15 cc. abs. alc. and treated with 5 g. 33% alc. $MeNH_2$ gives crystals. H_2O dissolves a yellow substance, 1-methyl 3-carbethoxy-α-naphthazolequinone (**II**), decomps. about 220°, and leaves a red substance, 2-bromo-3-methylacetamido-1,4-naphthoquinone, m. 165°. Two g. of **II** with 120 cc. 7% NaOH gives **VIII**, m. over 300°, 1 g. of which with 10 cc. concd. H_2SO_4 and 6 cc. 10 *N* HNO_2 give 1-methyl-2,3-ββ-naphthazoledione-4,9-quinone, m. 268°. To elucidate the mechanism of the above reactions the following reactions were conducted: 6,3,4-$Br(MeO)_2C_6H_2CH:CHCO_2Et$ and 2-bromo-3-carbethoxy-1,4-naphthoquinone both give an amide with $MeNH_2$, m. 183° and 164–5°, resp.

V. F. HARRINGTON

Tervalent nitrogen. I. The constitution of indazolecarboxylic acid. TARO HAYASHI. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 911–5(1930) (*Abstracts* 88 (in English), published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, Nos. 275–6).—Crude *indazolecarboxylic acid* (**I**) (Auwers, *C. A.* **14**, 65) gives, by treating it with 0.5 *N* KOH, 0.5 *N* H_2SO_4, hot AcOEt and PhMe, white crystals, m. 266–6.5°, whose EtOH soln. is optically inactive. *Brucine salt* m. 236–6.5°, $[\alpha]_D^{15}$ —102°; crystals from a mixt. of pyridine and EtOH (*a*) and H_2O (*b*) show following specific rotations:

(*a*) $[\alpha]_D^{15.5}$ —104° (*b*) $[\alpha]_D^{15.6}$ —86°, $[\alpha]^{15.6}$ —90° *Cinchonine salt*, m. 233.5–4°, $[\alpha]^{17}$ 18.1°, $[\alpha]^{17}$ 47.7°. *Quinine salt*, m. 245–6°, $[\alpha]^{18.5}$ 200°. The Me ester of I, methylated with MeI, followed by sapon. and recrystn. from 30% EtOH (K. v. Auwers, *loc. cit.*) gives *1-methylindazolecarboxylic acid* (II), m. 213–4°. Similarly, on methylation with $(MeO)_2SO_2$ and purification with MeOH, there results *2-methylindazolecarboxylic acid* (III), m. 225–6°. I, II and III show similar absorption curves but the absorption band of I is displaced to the side of shorter wave lengths. From these results I would seem to have the formula  rather than  , which contains an asym. C atom.

K. KONDA

Condensation of aldehydes and phenols. V. *m*-Chlorobenzaldi-β-naphthol. OTTO DISCHENDORFER AND HEINRICH MANZANO *Monatsh.* **57**, 20–30(1931); cf. *C. A.* **25**, 290.—β-$C_{10}H_7OH$ (10.2 g.) and 5 g. *m*-ClC_6H_4CHO in AcOH-concd. HCl, after standing 24 hrs., give *3-chlorobenzaldi-β-naphthol* (I), crystg. with 1 mol. AcOH, m. 178–9°; *Na salt*, needles; *di-Ac deriv.*, m. 216–7°; *di-Bz deriv.*, m. 164°; Me_2SO_4 gives a *mono-Me ether*, m. 168°. I in EtOH and 10% NaOH, treated with Br as long as a yellow ppt. forms, gives *dehydro-3-chlorobenzaldi-β-naphthol*, $C_{27}H_{17}ClO_2$, light yellow, m. 199°. I, AcOH and concd. H_2SO_4, warmed 1 hr. on the H_2O bath, give *ms-(3-chlorophenyl)dinaphthopyran* or *9-(3-chlorophenyl)-1,2,7,8-dibenzoxanthene* (II), m. 191–2°, sol. in warm concd. H_2SO_4 with a golden yellow color and a green fluorescence; II also results in 78% yield by warming the mixt. of $C_{10}H_7OH$ and ClC_6H_4CHO in AcOH-HCl 1 hr. on the H_2O bath. II in AcOH-HCl, oxidized with MnO_2 and treated with solid $FeCl_3$, gives *ms-3-chlorophenyldinaphthopyrylium chloride ferrichloride*, red needles, m. 225–6°; *mercurichloride*, red needles with green metallic luster, m. 272°; *perbromide*, red needles, m. 205–6° (decompn.), *perchlorate*, bright red needles with green luster. The $FeCl_3$ salt in Me_2CO contg. a little H_2O gives *ms-3-chlorophenyldinaphthopyranol*, m. 254–5°, sol. in cold concd H_2SO_4 with an orange red color. *Et ether*, m. 215–6°; *Me ether*, m. 217–8°, the ethers result from the $FeCl_3$ salt and the corresponding alc.

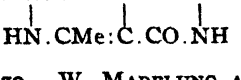
C. J. WEST

The structure of organic molecular compounds with principles of two- and three-dimensional variation. EDUARD HERTEL AND GEORG H. ROMER. *Z. physik. Chem.*, Abt. B., **11**, 77–89(1930).—X-ray investigation of org. mol. compds. shows that not all can be built up on the principle of 3-dimensional variation. A 2-dimensional variation explains anthracene-1,3,5-$C_6H_3(NO_2)_3$. A 1-dimensional variation explains [fluorene]$_3$[1,3,5-$C_6H_3(NO_2)_3$]$_4$. The crystal structures of 1,3,5-$C_6H_3(NO_2)_3$ and 2,4,6-$MeC_6H_2(NO_2)_3$ are discussed.

FOSTER D. SNELL

Structure of nitrofuran and the mechanism of nitration in the furan series. B. T. FREURE AND JOHN R. JOHNSON. *J. Am. Chem. Soc.* **53**, 1142–7(1931).—2-Nitrofuran, prepd. by the decarboxylation of 5-nitrofuroic acid, is identical with the compd. obtained from furan by nitration; the latter had been incorrectly formulated by Marquis (*Ann. chim. phys.* **4**, 216(1905)) to be 3-nitrofuran. Evidence is presented to support the view that the intermediate nitroacetates, produced in the nitration of various furan derivs. in Ac_2O soln., are ring structures rather than open-chain enols. The mechanism of the nitration process is suggested tentatively to be a 1,4-addn. to the furan ring, without scission of the O bridge. Me furoate yields a *nitroacetate*, $C_8H_9NO_7$, m. 96.3° (cor.); on catalytic hydrogenation 2.5 mols. H are absorbed, water decomposes the compd.; warming with C_5H_5N gives Me 5-nitrofuroate, m. 81.6° (cor.)

C. J. WEST



Local anesthetics in the pyrrole series. II. F. F. BLICKE AND E. S. BLAKE. *J. Am. Chem. Soc.* **53**, 1015–25(1931); cf. *C. A.* **24**, 1183.—In certain types of compds. at least, the following substitutions may be made in local anesthetics without loss, in a qual. sense, of anesthetic activity: the substitution of 2-pyrryl or Bz and 4-aminobenzoyl and the replacement of the NMe_2 and NEt_2 by the 1-pyrryl or the 1-pyrrolidyl nucleus. β-(1-Pyrryl)ethyl alc. (I), b_{12} 110–3° and K in C_6H_6, heated until the metal disappeared and then treated with BzCl, gave 78% of the *Bz deriv.*, $BzOCH_2CH_2NC_4H_4$, m. 53–5°. The K deriv. of I and *p*-$O_2NC_6H_4COCl$ in Et_2O-C_6H_6 give the *4-nitrobenzoate*, slightly yellow, m. 92–4°; catalytic reduction with Pt oxide in abs. EtOH gives the *4-aminobenzoate*, m. 87–8°. The *2-pyrroyl deriv.* m. 73–4°. *p*-$H_2NC_6H_4CO_2CH_2CH_2Cl$ and pyrrolidine, heated for 8 hrs. at 115–20°, give β-(*1-pyrrolidyl*)*ethyl 4-aminobenzoate*, m. 98–100°. γ-(1-Pyrryl)propyl alc., b_{748} 229–31°, gives a *Bz deriv.*, b_6 165–70°; the *4-nitrobenzoyl deriv.* m. 68–70°; the *4-aminobenzoyl deriv.*

m. 114–6°; the *2-pyrroyl deriv.* m. 69–70°. *γ-(1-Pyrrolidyl)propyl 4-aminobenzoate*, m. 84–5°. The K deriv. of MeEt(Me_2NCH_3)COH (II) and BzCl give stovaine. *Methylethyl(1-pyrrolidyl)methylcarbinyl benzoate*, from the carbinol, BzCl and C_6H_6 on heating 3 hrs. on the water bath. The *2-pyrroyl deriv.* of II m. 194–5°. *Dimethyl-1-pyrrylmethylcarbinol*, b_{2-3} 86–8°, gives oily Bz and 2-pyrroyl derivs. *Diethyl-1-pyrrylmethylcarbinol*, b_1 108–10°; the Bz deriv. was oily. The corresponding Et deriv. b_{4-5} 125–8°; the Bz deriv. was oily. The *4-(2-pyrroyl)-1-methyl derivs.* of the stable and labile forms of 2,2,6-trimethyl-4-hydroxypiperidine were prepd. from the 2 forms of 1-methylvinyldiacetone alkamine (K deriv.) and pyrroyl chloride; both m. 106–7° but a mixed m. p. was 80–3°. Notes are given on the prepn. of pyrrolidine. C. J. West

The preparation of hydroxyproline. Harriette K. Klabunde. *J. Biol. Chem.* **90**, 293–5(1931).—Hydroxyproline is readily obtained as a by-product during the isolation of proline from the products of the hydrolysis of gelatin by 33% H_2SO_4. In Town's procedure (*C. A.* **23**, 162) for the sepn. of the hydrolysis products proline and hydroxyproline occur in fraction 3, the Cu salts are sol. in both H_2O and MeOH. It is sepd. from proline by its insoly. in abs. alc. and can be isolated as the picrate from the alc.-insol. residue. Yields of 18–20 g. can be obtained from 1 kg. of gelatin

A. P. Lothrop

Heterocyclic ring systems. III. Ring closure reactions of heterocyclic *o*-dicarboxylic acids. Reinhard Seka and Heinrich Preissecker. *Monatsh.* **57**, 71–80 (1931); cf. *C. A.* **20**, 386.—Di-Et 2,5-diphenylfuran-3,4-dicarboxylate (1 mol.) and 7 mols. $N_2H_4.H_2O$, heated in EtOH 24 hrs. at 100–20°, give 76% of the *cyclohydrazide*, $C_{18}H_{12}O_3N_2$; the corresponding 2,5-di-Me ester reacts with the destruction of the ester Di-Et 2,5-dimethylpyrrole-3,4-dicarboxylate and 4.8 mols. $N_2H_4.H_2O$, heated 12 hrs. at 140–50°, give 80% of the *cyclohydrazide*, begins to carbonize at 295°, decomps. 359°; crystals from H_2O with 1 mol. solvent; the corresponding *2,5-di-Ph deriv.* m 324° (82% yield). *Pyrazolinedicarboxylic dihydrazide*, decomps. 170°, carbonizes 280° (86% yield); *dibenzohydrazone*, m. 218°; the ring system is very labile and could not be isolated. *2-N-Phenyl-1,2,3-triazole-4,5-dicarboxylic dihydrazide*, m. 225° (60% yield); *dibenzohydrazone*, m. 240°; heating *in vacuo* for 2 hrs. gives the *cyclohydrazide*, m. 317°. Imidazole-4,5-dicarboxylic acid does not give an anhydride or a cyclic hydrazide. **IV. Splitting of the furan ring systems with hydrazine hydrate.** *Ibid* 81–5.—Di-Et 2,5-dimethylfuran-3,4-dicarboxylate and 2.4 mols. $N_2H_4.H_2O$ in abs. EtOH, heated 24 hrs. at 100–20°, give the *compd.* $C_8H_{10}O_2N_4$, begins to carbonize at 315–20°; *tetra-Ac deriv.*, m. 140°; *tetra-Bz deriv.*, m. 190°. The same compd. is obtained by the action of $N_2H_4.H_2O$ upon $(EtO_2CCHAc)_2$. The compd. is believed to be 3,6-dimethyldihydropyridazine-4,5-dicarboxylic cyclohydrazide,

C. J. West

Bis(5-phenyl-2-pyrrole)indigo. W. Madelung and L. Obermann. *Ber.* **63B**, 2870–6(1930).—Posner (*C. A.* **21**, 87) considers the indigoid dyes to be intramol. quinhydrones (I), the secondary valences coming into play between the carbonyl O and the aromatic nucleus and the NH serving only to make the aromatic nucleus capable of entering into such a secondary valence union. It might be pointed out, however, that Friedländer and Kielbasinski's bis(5-phenyl-2-thiophene)indigo (*C. A.* **7**, 2193), in which the conditions demanded by P.s' theory are not fulfilled, is nevertheless very similar in color and properties to the normal thionaphtheneindigo. It seemed of interest to study more closely the relationship of a pyrroleindigo to the normal indole indigo, and *bis(5-phenyl-2-pyrrole)indigo* (II) was accordingly synthesized. It seemed that the logical starting material would be a phenylated deriv. of 3-hydroxypyrrole (designated as *pyrroxyl* by analogy with indoxyl) which should readily be converted by appropriate oxidizing agents into the corresponding indigo. K phenylglycidate, $NH_2CH_2CO_2H$ and KOH on the water bath yield 80% of the *di-K salt*, needles with $6H_2O$ from MeOH, m. 96°, crystals with $4H_2O$, m. 86°, from H_2O, of *α-hydroxy-β (carboxymethylamino)hydrocinnamic acid* (III), m. 235°. Attempts to apply the Heumann reaction to this acid were only partially successful in that the product of the KOH fusion yielded a very small quantity of an acid (not isolated) which on heating with water gave an oil which must have been the desired pyrroxyl, for treatment with $FeCl_3$ and water gave a small quantity of the corresponding II. KOH fusion is not practicable as a method of prepn., however, for by far the greater part of the III is completely destroyed. Attempts to bring about the ring closure by thermal decompn.

of the Ca or Th salt of III were likewise only partially successful. Ac_2O with the K salt of III, however, yielded 33% of *phenylacetylpyrroxylic acid (5-phenyl-1-acetyl-3-hydroxypyrrole-2-carboxylic acid)* (IV), m. 150°, decarboxylated by boiling 4 hrs. in water in a CO_2 atm. to the *pyrrole* (38% yield), m. 88°, gradually becoming reddish in the air. This with Ac_2O and a drop of concd. H_2SO_4 gave 33% of *5-phenyl-1,3-diacetoxypyrrole*, pale red, m. 181°, also obtained in small yield by heating III with Ac_2O. With $FeCl_3$ and HCl IV gave 80% II, brown-violet needles from C_5H_5N, m. somewhat above 300° with evolution of a red vapor, also insol. in most org. solvents in the cold, somewhat in hot C_6H_6 and AcOH, easily in hot C_5H_5N; the intensely red soln. in AcOH is turned pure blue by mineral acids; the H_2SO_4 soln. is orange-yellow. A 10^{-5} *M* soln. in C_5H_5N shows extinction below 560$\mu\mu$, lightening at 480–500$\mu\mu$, a 4×10^{-5} soln. in 50% H_2SO_4 lightening at 580–620$\mu\mu$, a 2×10^{-5} soln. of the acetate lightening at 540–560$\mu\mu$. With complex-forming metallic chlorides it forms complexes of different colors (blue with $SnCl_4$ in C_6H_6, brown-yellow with $TiCl_4$) which remain in soln., while dry HCl ppts. a blue HCl salt. The alk. $Na_2S_2O_4$ vat has only a slight affinity for cotton and imparts a very weak violet-red color. *Bis(5-Ac) deriv.*, brown-red, m. 220°, sol. in AcOH and C_6H_6 with intense red color, no longer has any basic properties or the ability to form metal compds. The properties of II show conclusively that P.s' theory as to the structure of indigo is incorrect. C. A. R.

Reaction of aliphatic imido ethers with hydrazine. WILFRID OBERHUMMER. *Monatsh.* 57, 106-11(1931).—HN:CHOEt and anhyd. N_2H_4 in abs. Et_2O give 25–30% of 1-amino-1,3,4-triazole, besides NH_4Cl and $N_2H_4.HCl$; with salts of N_2H_4 in abs. EtOH, only about 3% of the triazole was isolated. C. J. WEST

2-*N*-Phenyl-5-*C*-phenyl-1,2,3-triazolecarboxylic acids. MARIO GALLOTTI WITH G. BARRO AND L. SALTO. *Gazz. chim. ital.* 60, 866–72(1930).—In an analogous way to the transformation of phenanthrene to diphenic acid (I), the oxidation of 2-*N*-phenyl-1,2-naphtho-1,2,3-triazole leads to 2-*N*-phenyl-2,3-triazolylphenyl-*o*,4-dicarboxylic acid (II) (cf. Charrier and Gallotti, *C. A.* 19, 2205, 2954), but *2-N-phenyl-5-C-phenyl-1,2,3-triazole-4-carboxylic acid*, $PhC(:N.NPh.N:C)CO_2H$ (III) (see later) cannot be prepd. in this way because when II is heated alone or with soda lime or with NaOH it does not simply eliminate a CO_2H group or both CO_2H groups (as with I) with formation of III or *o*-$HO_2CC_6H_4C(:N.NPh.N:CH)$ (IV). The reaction is much more complicated, with formation of an anhydride deriv., whose constitution is not yet explained. It was of interest, therefore, in explaining the genetic relations between II and III and IV, and their possible transformation into 2-*N*-phenyl-5-*C*-phenyl-1,2,3-triazole (V), to attempt to prep. II, III and IV by some other method. The present paper describes the synthesis of III and unsuccessful attempts to prep. II. EtPhCO, treated with *iso*-$AmNO_2$ in the presence of a little anhyd. HCl, extd. with dil. NaOH, the ext. washed with Et_2O, AcOH added to the aq. residue and the ppt. recrystd. from dil. EtOH, yields 55–60% of BzC(:NOH)Me (VI). The latter and $PhNHNH_2$ yield, after recrystn. of the product from EtOH, almost 100% of *phenylhydrazone oxime* PhC(:NNHPh)C(:NOH)Me (VII), lustrous, m. 210°. VII (24 g.), added to Ac_2O (70 g.) at 50–5°, after several min. (when clear brown) made ice-cold and when solidified cold water (12 vols.) added, agitated for some time, the ppt. washed with cold water and recrystd. from 95% EtOH, yields the *Ac deriv.*, PhC(:NNHPh)C(:NOBz)Me (VIII), lemon-yellow, m. 137°. VIII (30 g.) and aq. Na_2CO_3 (14 g. in 650 cc.), heated 40 hrs. on a boiling water bath, cooled, satd. aq. $KMnO_4$ added until permanently red, excess $KMnO_4$ destroyed by aq. $NaHSO_3$ and dil. H_2SO_4, extd. with Et_2O, and the ext. evapd., yields 50% of crude 2-*N*-phenyl-4-*C*-methyl-5-*C*-phenyl-1,2,3-triazole (IX). IX (15 g.) and alk. $KMnO_4$ (26 g. and 66 cc. of 10% NaOH in 330 cc. water), refluxed for 100 hrs. (until homogeneous), decolorized with EtOH, filtered, the residue washed with boiling water, the combined filtrates concd., aq. HCl added, the ppt. recrystd. from boiling water, BzOH eliminated by subliming at 180° and the residue recrystd. repeatedly from water, yield III, m. 208–9°, stable above its m. p., but at 230° decomps. to an orange-yellow *substance* which sublimes at a still higher temp. This decompn. is more extensive than merely the elimination of CO_2, for in this case V would have been formed. III is a strong acid, turns blue litmus red, decomps. carbonates (with lively effervescence) and forms alk. salts extremely sol. in water and difficult to obtain in a cryst. state. Prepd. like VI, a 45–50% yield of *o*-$MeC_6H_4COC(:NOH)Me$ is obtained, and this with $PhNHNH_2$ yields almost 100% of the *phenylhydrazone oxime*, *o*-$MeC_6H_4C(:NNHPh)C(:NOH)Me$ (X), m. 175–7°. Following the same procedure as with VII, X (18 g.) and Ac_2O (55 g.) yield almost 100% of the *Ac*

deriv. of **X**, *o*-$MeC_6H_4C(:NNHPh)C(:NOAc)Me$ (**XI**), light yellow, m. 140°. **XI** (50 g.) and aq. Na_2CO_3 (30 g. in 1200 cc.), heated 40 hrs. on a water bath, and treated as before with $KMnO_4$, yields about 50% of crude *2-N-phenyl-4-C-methyl-5-C-tolyl-1,2,3-triazole.* C. C. DAVIS

A new synthesis of substituted thioxanthydrols. J. REILLY, P. J. DRUMM AND B. DALY. *Proc. Roy. Irish Acad.* **39B**, 515–22(1930); cf. *C. A.* **21**, 1253, 2885; **22**, 766.—$(p\text{-}MeC_6H_4)_2O$ (I) reacts with $C_6H_4(CO)_2O$ (II) or BzCl (III) and $AlCl_3$ to give only monosubstituted derivs. H_2SO_4 does not act upon the substituted *o*-benzoylbenzoic acid formed with II to yield a substituted anthraquinone but gives 2,7-dimethylfluoran (IV) instead. The product from the reaction of I with III is 9-phenyl-2,7-dimethylxanthydrol instead of the expected ketone so the formation of IV probably proceeds through a xanthydrol. Exactly similar results are obtained with $(p\text{-}MeC_6H_4)_2S$ (V) instead of I save that the condensation of V with III proceeds less smoothly. V, b_{16} 186°, m. 57.3°, was obtained in 70% yield by diazotizing $p\text{-}MeC_6H_4NH_2$, destroying the excess HNO_2 with $CO(NH_2)_2$ and slowly adding the diazonium chloride with vigorous stirring to $p\text{-}MeC_6H_4SH$ (VI) (1 mol.) in dil. NaOH (1 mol.) at 60–70°, keeping the mixt. at this temp. for 1 hr. after addn. is complete. (Explosive diazo thioethers result at lower temps.) $(p\text{-}MeC_6H_4)_2S_2$ (VII), m. 45.6°, was prepd. by adding 3.3 g. Br_2 to 5 g. VI in 100 cc. Et_2O at 0°. It dissolves in concd. H_2SO_4 to give violet to blue colors, whereas V gives only a faint green; hence it is probable that the violet color obtained by Dilthey and others (*C. A.* **24**, 91, 1855) with V was really due to VII. 2-*o*-Carboxybenzoyldi-*p*-tolyl sulfide (VIII) was prepd. by the Friedel and Craft reaction and by heating $p\text{-}MeC_6H_4SK$ with $o\text{-}(2,5\text{-}ClMeC_6H_3CO)C_6H_4CO_2K$ in the presence of a trace of Cu powder. The Ag salts were sparingly sol. in H_2O but sol. in dil. NH_4OH and the m. ps. and the mixed m. ps. were the same, 207°. VIII gave an oxime, m. 129°, and warmed with concd. H_2SO_4 gave 2,7-dimethylthiofluoran, m. 222°. 9-Phenyl-2,7-dimethylthioxanthydrol (**IX**) (from V and III), m 207°. It dissolves in AcOH with a pink color which becomes reddish orange on heating. It dissolves in H_2SO_4 to a reddish orange soln. with a brownish yellow fluorescence and the color is not destroyed nor is there pptn. on dilu with H_2O. Addn. of anhyd. $FeCl_3$ to an HCl satd. soln. of **IX** in AcOH forms a carmine-red ferrichloride, m. 202°. Satn. of a soln. of **IX** in anhyd. Et_2O with HCl gives deep red prisms of the chloride-HCl of **IX** which is readily sol. in $CHCl_3$ and in $PhNO_2$ but insol in Et_2O and in PhH. This compd. probably has a quinonoid rather than a sulfonium structure (cf. *Ber.* **37**, 2937; *C. A.* **4**, 1172). **IX** is slowly reduced by boiling in alc. HCl to the corresponding thioxanthene, m. 157°, but reduction by Zn in 80% AcOH is much more rapid. $PhNEt_2$ reacts with **IX** to give 4′-diethylamino-9,9-diphenyl-2,7-dimethylthioxanthene, colorless needles, m. 211°. C. H. PEET

Purely aliphatic *strepto*-pentamethin dyes. W. KÖNIG AND W. REGNER. *Ber.* **63B**, 2823–7(1930).—That compds. of the type $Alk_2N.(CH)_{2n-1}:NAlk_2X$ or, rather, $[Alk_2N^{+}\!\!-\!\!CH\!\!-\!\!CH\!\!-\!\!CH\!\!-\!\!CH\ldots\ldots CH\!\!-\!\!\!-\!\!NAlk_2]X^{-}$ are not only colored but have sufficient color strength and fiber affinity for practical dyeing purposes had not as yet been definitely proved, although indications of this had been obtained with the pentamethinium salts (n = 3). Zincke, at the beginning of his classical work on the cleavage of pyridine, had attempted to prep. the salts $[R_2N.CH.CH.CH.CH.CH.NR_2]X$ (I, R_2N = Me_2N and $CH_2.CH_2.CH_2.CH_2.CH_2.N$) but obtained them only in the form of very difficultly sol. $HgCl_2$ addn. compds., and he distinctly expressed the opinion that the salts themselves are so unstable that they cannot be isolated as such, and as the yellow color of the $HgCl_2$ compds. might to a certain degree be produced by the $HgCl_2$ the question whether these salts are real dyes remained unanswered. The desired evidence has now been supplied by the synthesis of the well-crystd. *perchlorates* (I, X = ClO_4). By the BrCN-C_5H_5N method they are formed only to a minor extent, together with many other products, which renders their purification difficult; they can also be obtained from $NHMe_2$ or piperidine with various di-*N*-arylaminopentamethinium salts, but these methods are far inferior to that depending on the treatment of the Zincke aldehydes, $ArAlkNCH:CHCH:CHCHO$, with $NHMe_2$ or piperidine in the presence of 1 equiv. of $HClO_4$. The 2 perchlorates are, in solid form, yellow with beautiful blue surface luster; they are relatively stable, easily dissolve in H_2O and alc. with green-yellow color and dye tannated cotton similarly to the auramines as regards tone and depth of color. The absorption curves of the 2 salts are almost identical; the NMe_2 compd. shows a single main band with a max. at 412$\mu\mu$ which is materially more persistent and narrower than the corresponding

band complex of auramine perchlorate; at around 300μμ the dye is extraordinarily transparent. Colorimetric comparison of alc. solns. of the Me_2N compd. and com. auramine G showed relative strengths of about 85:100. The fastness to light of the color on tannated wool was at least equal to that of auramine and the fastness to acids and alkalies was greater. A further striking property of the new salts is their strong luminescence under the Hanauer quartz lamp (intense green and orange-yellow for the Me_2N and piperidine compds., resp.); this fluorescence is shown only by the solids, not their solns., and is limited to the perchlorates. The *1,5-bisdimethylaminopentamethinium perchlorate* m. 165°; the *1,5-bis-N-piperidino salt* m. 111°. C. A. R.

Linear pentacene series. XX. Optical absorption of pentacene compounds. GUIDO MACHEK. *Monatsh.* **57**, 201–24(1931); cf. *C. A.* **24**, 5019.—Details are given, in tables and as curves, of the absorption of pentacene-6,13-monoquinone, pentacene-5,7,12,14-diquinone, 1,8-dihydroxypentacene-5,7,12,14-diquinone, the 6,13-di-HO deriv., the 1,8-di-Br deriv., the 6,13-di-Br deriv. and the 1,11-di-NO_2 deriv. in C_5H_5 and C_5H_5N and of the 1,11-di-Br deriv., the 2,9-di-Br deriv., the 1,8- and 1,11-diamino derivs., and the 1,8-di-NO_2 deriv. in C_5H_5N. The influence of the solvent and of the substituents of the absorption spectra is discussed. C. J. WEST

Alkali-organic compounds. VIII. Reactions between lithium alkyls, pyridines and condensed pyridine systems. K. ZIEGLER AND H. ZEISER. *Ann.* **485**, 174–92 (1931); cf. *C. A.* **24**, 5752.—Quinoline and a 1.32 *N* BuLi soln. in C_5H_5 give an addn. product (I) which, on decompn. with H_2O, gives 90% of *2-butyl-1,2-dihydroquinoline* (II), $b_{0.06}$ 128°, b_{14} 160–2°, d_4^{20} 0.997, n_α^{20} 1.5699, n_{He}^{20} 1.5772; *picrate*, deep red, m. 140–60°. Thermal decompn. of I gives 50–60% of *2-butylquinoline* (III), b_{14} 153° after purification through the *picrate*, m. 162–3°; the crude III also yields a *picrate*, m. 145°, probably that of the 4-Bu deriv. III has d_4^{20} 1.003, n_α^{20} 1.5699, n_{He}^{20} 1.5766. Heating II in 5 parts $PhNO_2$ gives 70–80% III. PhLi gives principally 2-phenylquinoline and a little 4-Ph deriv. Isoquinoline and BuLi give an unstable dihydro-1-butylisoquinoline, which $b_{0.4}$ about 135° and on dehydration by boiling in $PhNO_2$ gives 70% of *1-butylisoquinoline*, b_{14} 154–7°, b. 283–4°; *picrate*, m. 185.5°. PhLi gives the 1-Ph deriv. Acridine and BuLi give 9-butyl-9,10-dihydroacridine. 2-Butylpyridine and BuLi give *dibutylpyridine*, b. 243–4°; *chloroplatinate*, yellow, m. 192.5–3°. Quinaldine gives a Li deriv., which yields with PrBr III; $PhCH_2Cl$ gives 2-(β-phenylethyl)quinoline, m. 28°. Allyl chloride gives *2-(3-butenyl)quinoline*, b_{14} 152.5–4°, d_4^{20} 1.023, n_α^{20} 1.5853, n_{He}^{20} 1.5920; *picrate*, yellow, m. 143°. Ph_2CO gives *1,1-diphenyl-2-(2-quinolyl)ethanol*, m. 165°; H_2SO_4 in AcOH splits off H_2O and gives *2-(β,β-diphenylvinyl)quinoline*, m. 103–3.5°. The Li compd. of picoline and $PhCH_2Cl$ give 2-(β-phenylethyl)pyridine. C. J. WEST

Ultra-violet absorption spectra of the quinoline group. C. STANTON HICKS. *Australian J. Exptl. Biol. Med. Sci.* **7**, 171–81(1930).—Cinchonine, quinine, cinchotoxine, hydrocupreine, quinoline, cupreine, methylquinine, ethylquinine, ethylhydrocupreine, eucupine, yohimbine and euquinine were studied. The quinoline nucleus is the detg. factor in the absorption characteristics of the group. The absorption curves of stereoisomers were practically identical. Substitution in the quinoline HO group, reduction of the vinyl group, esterification, or opening of the quinuclidine nucleus, exert little or no effect upon the curves. The absorption curve of yohimbine is similar to that of indole and quinoline. C. G. KING

The alkyl-*py*-quinolines. (Generalization of the Skraup's reaction applied to α-alkylglycerols.) RAYMOND DELABY AND MLLE. JEANNE HIRON. *Compt. rend.* **191**, 845–7; *Bull. soc. chim.* [4], **47**, 1395–400(1930).—The alkyl-*py*-quinolines were obtained in low yields by means of the Skraup's reaction modified by the authors. They are clear yellow liquids possessing a strong odor, and were found to be mixts. of α- and γ-isomers, the former being present in greater quantities. The phys. properties of the following quinolines and their derivs. are: α-ethyl-, α-propyl and α-butylquinoline, resp., b_{18} 128-31°, 142–5°, 150–5°; d_{17} 1.050, 1.038, 1.020 (at 18°); n_D^{23} 1.5979, 1.5886, 1.5799; picrate, m. 148°, 159°, 143°; chloroplatinate, m. 188°, oily, 163.5°; chloromercurate, m. 118°, 112°, —; iodomercurate, m. 135°, —, —; iodobismuthate, m. 205° (decompn.), 186°, 163°. C. J. PEDERSEN

Methoxylated phenylquinolines or 2-phenyl-4-hydroxyquinoline. REINHARD SEKA AND WALTER FUCHS. *Monatsh.* **57**, 52–62(1931).—These compds. were prepd. as a preliminary step to the synthesis of certain flavones. PhNHBz gives 68.5% of a chloroimide, b_{20} 200–10°, m. 40°, which condenses with $CHNa(CO_2Et)_2$ in Et_2O, by heating 16 hrs. at 130–50°, giving 27.6% of the Et ester, m. 261–2°, of 2-phenyl-4-ketoquinoline-

carboxylic acid, which reacts with PCl_5 and NH_3 to give the *amide*, m. 208°, and with $N_2H_4.H_2O$ to give a *pyrazolone compd.*, $C_{16}H_{11}ON_3$, m. 317°. *p*-$MeOC_6H_4NHBz$, m. 156.5°, gives a chloroimide, b_{20} 220°, m. 63–4°; $CHNa(CO_2Et)_2$ gives 26.5% of the *Et ester*, m. 245°, of *2-phenyl-4-keto-6-methoxyquinoline-3-carboxylic acid*, m. 235°; sublimation at 12 mm. splits off CO_2, giving *2-phenyl-4-keto-6-methoxyquinoline*, m. 287°. *p*-$MeOC_6H_4NHCOC_6H_4OMe$-*p*, m. 202°, yields a *chloroimide*, b_{20} 215–25°, m. 109°; condensation with $CHNa(CO_2Et)_2$ gives the *Et ester*, m. 265–6°, of *2-p-methoxyphenyl-4-keto-6-methoxyquinoline-3-carboxylic acid*, m. 252°; the AcOH soln. shows a pale bluish yellow fluorescence. Sublimation in a high vacuum gives 70% of *2-p-methoxyphenyl-4-keto-6-methoxyquinoline*, crystg. with 1 mol. H_2O, m. 295°.

Pyrimidines. CXX. Action of ozone on uracil. Treat B. Johnson and Robert B. Flint. *J. Am. Chem. Soc.* **53**, 1077–81(1931); cf. *C. A.* **24**, 2462.—Uracil is not readily attacked by O_3 in glacial AcOH or 85% HCO_2H at room temp.; if, however, the pyrimidine is suspended in either solvent and washed O_3 is bubbled into such a suspension for several hrs., the uracil is finally completely destroyed; the 2 major products are oxaluric acid and *formylglyoxalurea*, $C_4H_4O_4N_2$, m. 162°, which does not yield a phenylhydrazone; the *Ag salt* crystallizes with 1 mol. H_2O; it reduces Fehling soln. and Tollens reagent; dil. H_2SO_4 gives HCHO and $CO(NH_2)_2$. Part of the uracil mol. is completely broken down with the formation of $CO(NH_2)_2$, $(CO_2H)_2$ and HCO_2H. **CXXI. Action of ozone on some derivatives of uracil.** *Ibid* 1082–7.—4-Methyluracil and O_3 give 67% of *acetylglyoxylurea*, m. 150°, $CO(NH_2)_2$ and $(CO_2H)_2$. 4-Phenyluracil gives benzoylglyoxylurea. Thymine gives 40% of $H_2NCONHCHO$; $AcCO_2H$ was not detected. 5-Bromouracil gives parabanic acid. 5-Nitrouracil reacts slowly (28 hrs.), giving parabanic and oxaluric acids. 1,3-Dimethyl-5-bromouracil gives *dimethyloxaluric acid*, m. 124–5°. These results show that the pyrimidine ring is destroyed with the formation of characteristic ureide constructions and simple oxidation products. In no case is the urea configuration of the respective pyrimidines destroyed by the O_3 treatment. The application of ozonization makes possible an improved technic for detg. the structure of uracil compds. The advantages gained exptly. become apparent when one is called upon to sep. and identify the products of oxidation.

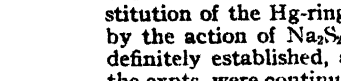
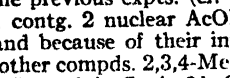
IV

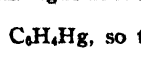


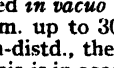
m. 79°, is dehydrated at 110° and then m. 141°, soly. in H_2O at 30° 1:20; *chloroplatinate*, decomps. 240°; *zinc chloride salt*, m. 171°; *mercurichloride*, softens at 250° and then decomps. without melting. I does not contain a *N*-alkyl group and cannot be dehydrogenated by $Hg(OAc)_2$ in 50% AcOH or by other methods; Br gives only a



loose Br addn. product. Oxidation with $KMnO_4$ gives only $(CO_2H)_2$. I is not reduced by Na and abs. EtOH, Sn and HCl or HI and red P. I is regarded as *decahydro-3,5,8-trimethyl-4,8-ethenopyrindacine*. Nitration of I gives a mixt. of 4 products when heated at 170° for 3 hrs.; *3,5-di-NO₂ deriv.* (II), m. 116.5° (*picrate*, m. 231°); *decahydro-3,5-dimethyl-3,5,7a-trinitro-4,8-ethenopyrindacine-8-carboxylic acid* (III), yellow, m. 347° (decompn.); *octahydro-7-methyl-7-nitro-1,4-carbonylpyrindine-3-carboxylic acid* (IV), m. 189–90° (decompn.), readily oxidized with alk. $KMnO_4$; berberonic acid, m. 240–1° (decompn.). C. J. WEST

Oxidation of heterocyclic arsenic compounds by iodine. G. A. RAZUVAEV AND V. S. MALINOVSKII. *Ber.* **64B**, 120–30(1931); cf. *C. A.* **24**, 2132.—A new method for the *detn. of As* in alkyl and aryl derivs. of 9,10-dihydrophenarsazine (I), in 10-chloro-9,10-dihydrophenarsazine (II), in 9,10-dihydrophenarsazine oxide (III) and in phenoxarsine oxide (IV). A soln. of the sample in 15–20 cc. EtOH was dild. with H_2O until cloudy, and titrated with alc. I (0.1 *N* for 0.3–0.5 g. samples, 0.02 *N* for 0.1 g. sample) to a bright yellow color. During titration H_2O was added 2 or 3 times, so that the total vol. was 60–100 cc. The color appearing on the addn. of the 1st portions of I disappeared at once on shaking. Toward the end of the titration, 10–30 sec. was required for disappearance of the color. Finally 1–2 drops of I soln. gave a bright yellow color which lasted 24–48 hrs. This method is good for all derivs. of I which are not colored or contaminated with colored substances. The oxidation products must also be colorless or nearly so. The method is not good for I, since a brown color developed and obscured the end point. With IV, which is insol. in EtOH, the method was modified With both IV and II, the addn. of $NaHCO_3$ during the titration was advantageous. The results obtained by this new method were within the permissible limits of error. Before the oxidation products could be studied it was necessary to remove the HI also formed. This was done (1) by neutralization with NaOH, or (2) by pptn. with an excess of freshly pptd. Ag_2O and removal of the ppt. of AgI and Ag_2O by filtration. The products were obtained on concn. of the soln. and with a nearly theoretical yield in each case. Method 1 gave mainly the di-OH derivs. of the 10-R derivs. of I; method 2 gave the corresponding oxides. The products usually contained some H_2O of crystn. or hygroscopic moisture, which was removed by drying *in vacuo* (5–10 mm.) over P_2O_5. The di-OH derivs. dried *in vacuo* at 70–150° gave the oxides. The following oxidation products were isolated: di-OH deriv. of 10-Me deriv. of I, m. 210–15° (80% yield); the corresponding oxide (also obtained by drying the di-OH deriv. over P_2O_5) decomps. without melting at 256–7°; the di-OH deriv. of the 10-Et deriv. of I m. 141–3° when contg. H_2O; it m. 141–183° when H_2O-free; the corresponding oxide m. 239°; the di-OH deriv. of the 10-Pr deriv. of I m. 93°; the corresponding oxide m. 111–2°; the di-OH deriv. of 10-iso-Am deriv. of I m. 95–6°; the corresponding oxide m. 101–2°, hygroscopic; the 10-Ph deriv. of I was not obtained, the product being always the oxide, m. 280–300° (decompn.). Oxidation of III gave phenarsazinic acid (V); of II gave V; of IV gave phenoxarsinic acid, m. 221–2°; of $AsPh_3$ gave triphenylarsine dihydroxide, m. 112–4°. These oxidation products gave dark-red or cherry-red solns. in concd. H_2SO_4. The following derivs. of I were prepd.: 10-Pr deriv., from MgPrI and II, m. 81–2°; 10-iso-Am deriv., from iso-AmMgBr and II, m. 76–8°; 10-Ph deriv., from PhMgBr and II, m. 148–9°. LOUISE KELLEY



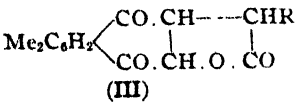


The formation of a closed heterocyclic ring of mercury atoms. II. L. VECCHIOTTI AND M. PANCIERA. *Gazz. chim. ital.* **60**, 904–9(1930); cf. *C. A.* **25**, 957.—The constitution of the Hg-ring compds. prepd. in the previous expts. (cf. V., *C. A.* **23**, 3447) by the action of $Na_2S_2O_3$ on $PhNH_2$ derivs. contg. 2 nuclear AcOHg groups was not definitely established, and in view of this and because of their interesting character, the expts. were continued with the prepn. of other compds. 2,3,4-$Me(AcOHg)_2C_6H_2NH_2$. 3,4-Diacetomercurio-*o*-toluidine (cf. V. and Copertini, *C. A.* **24**, 348) (6 g.) and aq $Na_2S_2O_3$ (10 g. in 10 cc.), let stand 1 month in darkness, filtered, the residue washed with water and dried over H_2SO_4 yield *3,4-bimercuri-bi-o-toluidine* (I), m. 200°, could not be obtained pure enough to det. the mol. wt. Its constitution is either

or

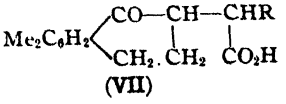
Because of this doubt, a quite different method was tried to obtain a compd., the identity of which could be more easily established. *o*-$C_6H_4Br_2$ (50 g.), 2% Hg-Na (500 g.), dry gasoline (50 g.) and AcOEt (5 g.), refluxed 5 hrs. at 120°, filtered hot, the gray product in the residue sepd. mechanically from the Hg, dried in air, washed with boiling water, dried, recrystd. from boiling cumene (because of the insoly. in all ordinary solvents) and washed with EtOH and then with Et_2O, and dried *in vacuo* over H_2SO_4, yields *1,2-bi-*

mercuribiphenyl (II), turns light brown when heated, but does not m. up to 300°. Its analysis corresponds to C_6H_4Hg, so that it is either  or $C_6H_4{:}Hg$. To decide between these 2 formulas, its decompn. was studied. II and glacial AcOH, refluxed for a long time, filtered hot, the filtrate cooled, and fractionally crystd. and the product dried *in vacuo* over H_2SO_4, yield a *bis(acetomercuri)benzene*, $(AcOHg)_2C_6H_4$ (III), does not m. up to 300°. The mother liquor from this crystn., neutralized with KOH and steam-distd., the distillate extd. with Et_2O and the Et_2O evapd. from the ext. yields C_6H_6. This is in accordance with the 1st formula of II given above, and with the reaction  + 2AcOH ⟶ III + C_6H_6. III (6 g.) and I (7.68 g.) in aq. KI (6 g. in 60 cc.), intimately mixed, let stand 24 hrs. at room temp., steam-distd., the distillate extd. with Et_2O, the ext. evapd., the residue cooled with ice, the solidified product dissolved in a min. of boiling EtOH, the soln. made ice-cold and the ppt. dried *in vacuo* over H_2SO_4, yields *o*-$C_6H_4I_2$, m. 27° (cf. Körner and Wender, *Gazz. chim. ital.* **17**, 491). This proves conclusively that II has the 1st formula given above.



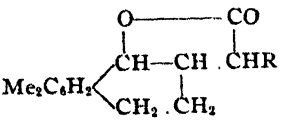
C. C. Davis

Attempted synthesis of a tricyclic system present in morphine. Richard H. Manske. *J. Am. Chem. Soc.* **53**, 1104–11(1931).—An attempt, thus far unsuccessful, to effect the synthesis of a portion of the morphine nucleus, is reported. Details are given of the prepn. of phenylsuccinic and β-phenylglutaric acids. Reduction of $EtO_2C{-}CHPhCH_2CO_2Et$ with Na and EtOH gives *2-phenylbutane-1,4-diol*, b_4 165°, sets to a solid glass at −10°; *bisphenylurethan*, m. 113°; dry HBr in Ac_2O gives the *dibromide*, b_{16} 173–5°, loses HBr readily and in several days turns turbid and dark; NaCN, followed by hydrolysis, gives *β-phenyladipic acid*, m. 146°; with PCl_5 and then $AlCl_3$ in CS_2, there results *1-keto-1,2,3,4-tetrahydronaphthalene-4-acetic acid*, but the yield was so small that it was not obtained in a state of purity; there also resulted a small quantity of *4,9-diketo-1,2,3,4-tetrahydroacenaphthene*, m. 149°. *3-Phenylpentane-1,5-diol*, b_4 174°; *bisphenylurethan*, m. 112-3°; the *dibromide*, b_{16} 177-82°, loses HBr readily and with EtOH-PhONa gives *3-phenyl-1,5-diphenoxypentane*, m. 72°. *γ-Phenylpimelic acid*, m. 84°; PCl_5, followed by $AlCl_3$, gives 53% of *1-keto-1,2,3,4-tetrahydronaphthalene-4-propionic acid*, m. 108-9°; the *Me ester* is a viscous oil; there also results in this condensation *hexahydrobenzonaphthene-α,α'-dione*, m. 111°; *dioxime*, m. 253-4°. β-Phenylglutaric acid, PCl_5 and $AlCl_3$ give *hydrind-1-one-3-acetic acid*, m. 155°; *Me ester*, b_{18} 175-80°, m. 54°. In the reduction of esters with Na, the use of EtOH is as satisfactory as the toluene method; in the case of the ester contg $PhO(CH_2)_3CN$, there results *α-phenoxybutyr-δ-phenoxybutylamide*, m. 94-5°. $PhO(CH_2)_5OH$ is obtained in 75% yield with the Na-EtOH reduction; $HO(CH_2)_{10}OH$ is obtained in 77% yield.



C. J. West

Syntheses in the field of the santonin derivatives. A. E. Chichibabin and M. N Shchukina. *Ber.* **63B**, 2793–806(1930).—This paper is published because of the appearance of the communications of Clemo, Haworth and Walton (*C. A.* **24**, 4046) and of Berg (*C. A.* **24**, 4300). The method chosen for the synthesis of santonin and related substances is closely analogous to that used for the synthesis of pilopic acid (*C. A.* **24**, 3015). Succinic esters and their homologs are condensed with oxalic esters to oxalosuccinic esters, $R'O_2CCHRCH(CO_2R')COCO_2R'$, which are reduced to the HO esters, $R'O_2CCHRCH(CO_2R')CH(OH)CO_2R'$, and these on heating yield the lactonic acid esters, O CO CHR CH(CO_2R') $CHCO_2R'$ which contain 3 asym. C atoms and may therefore exist in 4 optically inactive stereoisomeric forms. By condensation of the anhydrides or chloroanhydrides of these lactonic acids with aromatic compds. (especially *p*-xylene and $2,5\text{-}Me_2C_6H_3OMe$) it was planned to prep. the products of incomplete condensation, $2,5\text{-}Me_2C_6H_2COR''$ (I) and $2,5,4\text{-}Me_2(MeO)C_6H_2COR''$ (II) (R'' = —CH.O.CO.CHR.$CHCO_2H$), and those of complete condensation (III and IV) (IV = III with $Me_2(MeO)C_6H$ instead of $Me_2C_6H_2$). I and II on reduction should yield the dibasic acids $Me_2C_6H_2CH_2CH_2CH(CO_2H)CHRCO_2H$ (V) and $Me_2(MeO)C_6H_2CH_2CH_2CH(CO_2H)CHRCO_2H$ (VI) which by ring closure should give the tetrahydronaphthalene derivs. VII and VIII. Reduction of the ketone C:O group in VII and VIII and subsequent lactone formation should give compds. with structures (IX and X) which, when R = Me, have been shown by the work of C., H. and W. to be the structures of hyposantonin and desmotroposantonin Me ether. IX and X



are also obtained by the method successfully used by C., H. and W., *viz.*, ring closure of **VII** and **VIII** to the unsatd. lactones, **XI** and **XII**, and reduction. Reduction of the two ketone C:O groups in **III** and **IV** should give compds. (**XIII** and **XIV**) having the structures which recently have usually been assigned to hyposantonin and desmotroposantonin Me ether. Sapon. of the MeO group in **X** and **XIV** would give the compds. (**XV** and **XVI**) having the 2 structures which have been given to desmotroposantonin. **XIII** and **XIV** can also be obtained in a more round-about way: reduction of **I** and **II** to $Me_2C_6H_3CH_2R''$ (**XVII**) and $Me_2(MeO)C_6H_2CH_2R''$ (**XVIII**) (R in R'' (see above) = Me), ring closure to the tetrahydronaphthalene derivs. (**XIX** and **XX**) and the reduction of the C:O groups to CH_2. All these syntheses might be rendered difficult by the presence of the 3 asym. C atoms but it was hoped that the intermediate products corresponding to the stable hyposantonin and desmotroposantonin might also be stable and therefore the most easily formed modifications. The work has not yet been completed and the results so far obtained are published now to reserve the right of further investigation along this new broad road to the synthesis of santonin-like lactones. From $EtO_2CCHMeCH_2CO_2Et$, $(CO_2Et)_2$ and NaOEt was obtained 80–90% EtO_2C-$CHMeCH(CO_2Et)COCO_2Et$ (probably a mixt. of stereoisomers), converted by reduction with amalgamated Al in moist Et_2O into 85% of a mixt. of esters of 3 stereoisomeric HO acids. On distn. *in vacuo* elimination of EtOH and lactone formation occurred and 200 g. of the reduction product after 15 fractionations yielded 88 g. liquid ester b_{13} 182–3°, d_{20} 1.1717, n_D 1.4498, 18 g. b_{13} 186–7°, d_{20} 1.1747, n_D^{20} 1.4507 and 13 g. solid ester, b_{13} 200–4°, m. 70°. Of these *di-Et 3-methylbutanolide-1,2-dicarboxylates*, the first yielded with boiling HCl a free *acid* m. 179–82°, which with AcCl gave, along with dimethylmaleic anhydride, the *anhydride*, m. 162°; *anilide*, from the anhydride and boiling $PhNH_2$, m. 212–4°. The ester b_{13} 186–7° gave an *acid* m. 186°, which strongly depressed the m. p. of the preceding acid and was for the most part unchanged by boiling AcCl, the small quantity which did react giving the above anhydride. The 2 acids are apparently *cis-trans* isomers. The solid ester gave an *acid* m. 185°, forming with AcCl an *anhydride* m. 201° which partly isomerizes into the 162° anhydride on distn. *in vacuo* and yields the same anilide with $PhNH_2$. The 162° anhydride with *p*-xylene and $AlCl_3$ gave the *acid* **I**, m. 171–3°, converted by heating 5 min. in concd. H_2SO_4 on the H_2O bath into an *isomer* m. 150°, which is obtained directly from the chloroanhydride of the 181–2° acid with *p*-xylene and $AlCl_3$. **I** and its isomer with amalgamated Zn and concd. HCl gave the *compd.* **V**, m. 161–3°, but with amalgamated Zn and AcOH they yielded a *compd* $2,5\text{-}Me_2C_6H_3COCH_2CH(CO_2H)CHMeCO_2H$, m. 169–72°, which is reduced to **V** by the Clemmensen method. The *chloroanhydride*, m. 182° (decompn.), of **I**, heated at 160–85°, yields the *diketone* **III**, light yellow, m. 137–9°, reacts neutral to litmus, sol. in boiling 10% but only difficultly in 0.1 *N* NaOH. The 162° anhydride with $2,5\text{-}Me_2C_6H_3OMe$ gives the *ketolactonic acid* **II**, m. 207–8° (together with a small quantity of a substance m. 156°), which is reduced by the Clemmensen method to the compd. **VI**, m. 131°, converted by demethylation with HI into the cryst. product from which was obtained, by the method of C., H. and W., their unsatd. lactone m. 250–2°.

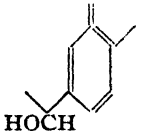
Sulfur sugars and their derivatives. XV. Nature of the sugar of mustard oil glucosides. Wilhelm Schneider, Hellmuth Fischer and Walter Specht. *Ber.* **63B**, 2787–98(1930); cf. *C. A.* **23**, 4932.—It has been established that the natural mustard oil glucosides are *S*-glucosides of the type $RN{:}C(OSO_3M)SC_6H_{11}O_5$ (M = K, an org. base, etc.) and it only remained to det. whether they are α- or β-glucosides. From their negative rotation and the fact that all plant glucosides hitherto investigated have been found to be derivs. of β-glucose, it was to be expected that these *S*-glucosides would also belong to the β-series, although Wrede had reported that the thio-

sugar obtained from sinigrin is not identical with the thioglucose synthesized by Schneider and collaborators which, from its method of prepn. and reactions, seemed to be beyond doubt a β-compd. The subsequent prepn. in pure cryst. form of the Na salts of the 2 mutameric thioglucoses and the exact characterization of the optical behavior of the free thiosugar undermined the ground on which Wrede based his conclusion that the thiosugar from sinigrin is the α-form and again left open the question of its configuration. Since the 2 typical glucosidases, emulsin and yeast maltase, cannot be used, the mustard oil glucosides being hydrolyzed only by myrosinase, which is sp. for them alone, and since the synthesis of these glucosides has not yet been effected, their configuration could be settled only by detg. that of the glucose set free by their cleavage. Preliminary expts. along these lines on sinigrin have already been described (S. and Becker, *C. A.* **24**, 2466). Contrary to this preliminary announcement, however, the initial rotation of the glucose liberated by myrosinase is not unequivocal. It was found that it is impossible to prep. an optically inactive myrosinase soln. and its rotation is so affected by NH_3 as to render it impossible to recognize with certainty any mutarotation effect of the sugar split off. The expts. described in the present paper, however, confirm the results given in the preliminary note and lead to the same conclusion on a firmer exptl. basis. The mustard oil glucosides are smoothly and rapidly decompd. by aq. $AgNO_3$, with pptn. of allyl mustard oil-$AgSO_4$ in the case of sinigrin and a mixt. of the mustard oil and sinapic acid Ag compds. in that of sinalbin, and if the HNO_3 set free is at once neutralized by carrying out the reaction in the presence of Ba or Ag carbonate, the reaction is practically complete in 0.5 hr. and the mutarotation of the liberated glucose is not unduly accelerated by the acid. Hg″ salts can also be used, although not so satisfactorily, for the decompn. From sinigrin, m. 127–9°, $[\alpha]_D^{18}$ —16.4° (H_2O, *c* 2.622), with 3 mols. $AgNO_3$ was obtained a glucose soln. with $[\alpha]_D^{20}$ changing from 81.0° 40 min. after adding the $AgNO_3$ to 64.7° after 120 min. and 53.7° for $t = \infty$ (20–30 hrs.). Sinalbin, m. 84–5°, $[\alpha]_D^{20}$ —8.76° (H_2O, *c* 0.2967), gave a glucose soln. with $[\alpha]_D^{20}$ 93.7°, 52.4° (const.) after 40 and 120 min., resp. With $Hg(OAc)_2$ the decompn. is so slow that at the end of 1 hr. the rotation is still rising because of the increasing concn. of sugar with high rotation, and only after 2 hrs. does the mutarotation begin to manifest itself by a decrease in the rotation. These results show plainly that the sugar split off is the α-form, and would seem to confirm Wrede's conclusion that sinigrin and sinapin are α-glucosides. The synthetic Na β-glucothiosate should then give with $AgNO_3$ β-glucose with a low initial rotation, but as a matter of fact there was obtained a glucose soln. with $[\alpha]_D^{20}$ changing from 68.5° after 45 min. to a const. value of 48.5° (that the final value is somewhat lower than the equil. value, 52.5°, for glucose is due to the fact that the colloidal glucothiose-Ag compd. is adsorbed on the $BaCO_3$-Ag_2S; if the decompn. is carried out in the absence of $BaCO_3$ the mutarotation is considerably accelerated but leads to const. values very close to 52.5°). In the desulfurization of β-glucothiose by $AgNO_3$, the glucose is therefore split off as α-glucose, and as the reaction is entirely analogous to that with the mustard oil glucosides the latter are certainly β-glucosides. This is confirmed by the formation of β,β-diglucosyl disulfide octaacetate, m. 140°, $[\alpha]_D^{21}$ —158.7° in $(CHCl_2)_2$, from sinigrin heated on the H_2O bath with about 2.2 mols. of 0.1 *N* NaOH, cooled to room temp., neutralized, immediately treated with 0.1 *N* I as long as it is used up, evapd. *in vacuo* and treated with Ac_2O in cold C_5H_5N. C. A. R.

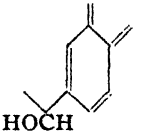
Digitalinum verum. H. Kiliani. *Ber.* **63B**, 2866–9(1930).—For the hydrolysis of *Digitalinum verum* (I) K. had previously always used a dil. HCl contg. alc. and then treated the sugar soln., after removal of the digitaligenin, with Br to sep. the oxidation product of the digitalose as digitalonolactone (II) from the *d*-gluconic acid formed at the same time, but the yield of II was very small (never more than 10%). It therefore seemed desirable to devise another cleavage method for such glucosides, especially since the use of HCl contg. alc. leads to the formation of considerable quantities of ethylsugars, which greatly interfere with the sepn. and identification of the individual sugars. K. had left, from his earlier work, several kg. of digitalis by-alkaloids which, he found, still contained considerable quantities of I. This he extd. by a method similar to that used before but differing in the relative proportions of substance and solvents employed; he will publish the details of this method after he has tested it on a com. by-product to be soon supplied to him. The 90 g. of crude I he obtained by his new method was purified by the method previously described but for its hydrolysis he used an acid contg. AcOH instead of alc. (35 cc. glacial AcOH, 55 cc. H_2O and 10 cc. concd. HCl); the solvent action of the AcOH on both the glucoside and the genin is

about the same as that of the alc., no ethylsugars are formed and, because of the dilu. and the presence of HCl, the danger of acetylation is exceedingly small. Details of the hydrolysis and of the working up of the sugar soln. for II are given. The yield of II is regularly around 40%. Attention is called to an error in Haworth's book, *The Constitution of Sugars*. C. A. R.

Strophanthin. XIX. The dehydrogenation of strophanthidin and gitoxigenin WALTER A. JACOBS AND ELMER E. FLECK. *Science* **73**, 133–4(1931); cf. *C. A.* **24**, 5773.—The Se method of dehydrogenating is used and gives promising results pointing toward the structure of the hydrocarbon upon which these aglucones are built. Four fractions were obtained from strophanthidin and 2 from gitoxigenin. The hydrocarbon obtained from fraction II from gitoxigenin resembles the $C_{23}H_{18}$ hydrocarbon obtained from fraction 4 from strophanthidin. W. H. TIFFANY



Unedoside, a new glucoside hydrolyzable by emulsin, from the fresh leaves and branches of Arbutus unedo L. M. BRIDEL AND (MLLE.) C. BOURDOUIL. *J. pharm. chim.* [8], **12**, 241–53; *Bull. soc. chim. biol.* **12**, 910–20(1930). cf. Bourquelot and Fichtenholz, *C. A.* **4**, 2948.—Unedoside (I), obtained with a yield of only 0.1 g. per kg. of fresh leaves or branches, is sol. in water (3% at ordinary temp.) and 95% alc. and insol. in Et_2O, crystallizes from Me_2CO contg. 7% water in long prisms, m. 225.5°; loses only 0.35% of its wt. *in vacuo* at 50°, $[\alpha]_D$ −112.43°, $[\alpha]_{5461}$ −133.92°, reducing power, 0.853 that of dextrose, similar to that of verbenaloside (verbenalin; Bourdier, *C. A.* **2**, 661, 1595); the latter differs, however, by a higher m. p. and lower $[\alpha]$. Upon hydrolysis with H_2SO_4 I gives a black ppt. caused by the decompn. of the nonglucidic product *unedol;* the rotation becomes pos., but the reducing power diminishes by more than 20%. Following hydrolysis of I with emulsin, unedol does not form a black ppt. as with H_2SO_4, but the soln. turns red-brown, unedol ppts. and the reducing power of the soln. diminishes; hence I is the only glucoside whose hydrolysis is characterized by a *loss* of reducing power. Unedol has been crystd ; it also possesses reducing properties. A bibliography of 8 references is added. S. WALDBOTT

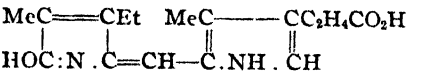


Chlorophyll. XV. Phyllo- and pseudophylloerythrins. H. FISCHER, OTTO MOLDENHAUER AND OSKAR SÜS. *Ann.* **485**, 1–25(1931); cf. *C. A.* **25**, 961.—Phylloerythrin (I) gives with MeOH-KOH a quant. yield of the *K salt*, $C_{33}H_{33}N_4O_3K$, sol. in H_2O but insol. in all org. solvents; 12% HCl gives I. Heating I with *m*-$C_6H_4(OH)_2$ gives a porphyrin spectroscopically identical with pyrroporphyrin I in AcOH-concd. HCl, treated with H_2O_2, gives a Cl deriv , probably a mixt. of $C_{32}H_{32}N_4O_3Cl_2$ and $C_{33}H_{33}N_4O_3Cl$. I and $H_2NCONHNH_2$ in C_5H_5N yield the *semicarbazone*, small needles, $C_{34}H_{37}N_7O_3$, for which the spectrum in C_5H_5N is given; the max. is at 631.2; the *Me ester*, $C_{36}H_{39}N_7O_3$, forms deep red prismatic needles. $N_2H_4 \cdot H_2O$ and I give a *hydrazone*, prismatic needles with a red-violet surface luster; the spectrum is shifted to the violet; after short exposure to light the spectrum of I is again seen I also yields an *oxime*, $C_{33}H_{35}N_6O_3$, prismatic needles; the *Me ester*, m. 270° (decompn.), forms deep red needles. Reduction of I by heating with EtONa and $N_2H_4 \cdot H_2O$ 6 hrs. at 165–70° gives *desoxophylloerythrin* (II), $C_{33}H_{36}N_4O_2$, prisms or prismatic needles with blue-violet surface luster; HCl no. about 1.5; the spectrum is given in pyridine-ether and HCl; *Me ester*, m. 264° (cor.); *Fe complex*, $C_{34}H_{36}N_4O_2FeCl$, prismatic needles; *Cu salt*, tablets from $CHCl_3$-MeOH. Reduction of the semicarbazone of I with EtONa at 168° gives a porphyrin spectroscopically identical with isopheoporphyrin a_3. Pseudophylloerythrin (III) with ice-cold oleum for 15 min. gives I; while 2 mols. I crystallizes with 1 mol. $CHCl_3$, III does not do so, even after heating with HCO_2H 24 hrs., showing that III is unchanged by this treatment. Oxidation of III with H_2O_2 gives rhodoporphyrin and a 2nd product, probably isochloroporphyrin e_4. III gives an *oxime* (*Me ester*) and a *semicarbazone*. The di-Me ester of diacetyldeuteroporphyrin yields a *dioxime*, needles, and a *semicarbazone*, for which the spectra are given. Reduction of this ester gives a mixt. of hemo- and mesoporphyrins. II does not react with EtONa and N_2H_4 at 170°. 3,4′-Dimethyl-4,3′-diethyl-5-bromo-5′-bromomethylpyrromethene-HBr and 3,3′,4′,5′-tetramethyl-4-propionic acid-pyrromethene-HBr, on fusion with $(CH_2CO_2H)_2$ at 210° give *1,3,5,6,7-pentamethyl-2,4-diethyl-8-propionic acid-porphin*, whose *Me ester*, $C_{38}H_{48}O_2N_4$, m. 242° (cor.); its spectrum is entirely different from that of II. The Fe and Zn salts of III are reported. C. J. WEST

The enzymic hydrolysis of gelatin in its relation to the formation of diacipiperazines. A. BLANCHETIÈRE. *Compt. rend.* **191**, 1479–81(1930); cf. *C. A.* **23**, 1619, 2698, **4219**.—A relation has been pointed out between the N of the diacipiperazines formed in fermentative hydrolysis of proteins and the N content of certain amino acids known to be resistant to hydrolysis. Gelatin differs much in chem. behavior from ovalbumin and gliadin. In peptic digestion, the ratio of diacipiperazine N in

gelatin as compared with that in ovalbumin is 0.64 while the corresponding ratio of amino acid to ovalbumin is 0.97. In comparative expts., the ratio of diacipiperazine N in gelatin to that in gliadin is 0.295 while the corresponding ratio of amino acid to gliadin is 0.471. This is interpreted to indicate that the diacipiperazine N is less in gelatin than in certain resistant anhydrides of amino acids, and also that gelatin has less N linked by cyclopeptidic structure than has ovalbumin or gliadin. N. M. N.

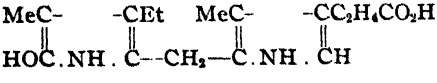
Ergosterol and some of its derivatives. Z. DE BOE. *Bull. acad. roy. méd. Belg.* **10**, 336–75(1930); cf. Castille, *C. A.* **24**, 5320.—A critical review, with 34 references, of the literature on the *isomerization, reduction* and *oxidation derivs.* of *ergosterol A* (I) and a study of certain isomerizations and reductions of I. *"Iso-ergosterol"* was prepd. according to Reindel (cf. *C. A.* **21**, 1464) and, confirming Heilbron (*C. A.* **24**, 1388), shown to consist of a mixt. of *isoergosterol B* (II) and *ergosterol B* (III), both of which possess a secondary alc. group and 3 double bonds and correspond to $C_{27}H_{42}O$. II, crystd. from MeOH-EtOAc (4:1) or EtOH, m. 135–6°, has α —66° and forms an *acetate* (IV), m. 112°. III m. 145–6° and turns on standing into II. Sapon. of its *acetate* (V), m. 139°, yields mainly II. The ultra-violet absorption spectra of II–V in C_6H_{14} and EtOH-Et_2O are described. A mixt. of II and III was also obtained by the action on I of dry HBr at 0°, while by boiling I with H_2SO_4 in EtOH only II was formed. From a soln. of I in dry pyridine and BzCl kept at 0°, *ergosterol benzoate*, m. 164–5° after recrystns. from MeOH and Et_2O, was isolated. Its absorption spectrum in EtOH and C_6H_{14} is described. By heating I with BzCl to 150–70°, *isoergosterol benzoate*, m. 125–6° after recrystn. from MeOH-EtOAc, is formed. Sapon. with KOEt yields a mixt. of II and III. From the absorption spectra the conclusion is drawn that the isomerization of I into II and III consists of a shifting of double bonds such as



By refluxing I in AmOH in presence of Na and avoiding air oxidation, *dihydroergosterol A*, $C_{27}H_{44}O$ (VI), free of I and m. 208–9° after crystn. from dry MeOH-EtOAc or dry Et_2O, was obtained, while crystn. from ordinary EtOH gave the *dihydrate* of VI, m. 205° and retaining 2 H_2O even after 6 hrs. at 120° over H_2SO_4. From the MeOH-EtOAc filtrates *isodihydroergosterol A*, $C_{27}H_{44}O$ (VII), m. 173–4°, was isolated. Sapon. of the *acetate* of VI, m. 181°, gave VII. These relations are confirmed by a study of the absorption spectra. A similar reduction of III could not be realized, but when III was refluxed in AmOH in presence of Na, *α-isoergosterol B*, m. 188–90°, possessing 3 double bonds and 1 secondary alc. group, could be isolated. Sapon. of its *acetate* m. 112° gave II. The corresponding absorption spectra are reported. It is shown that Heilbron's observations on the alleged isomerization of VI (*C. A.* **24**, 623) by HCl gas are merely due to a m.-p. depression caused by transformation of I, present in impure prepns. of VI, into III; no isomerization being observed with pure VI. An attempt to reduce I by HI and red P at 230° led to a non-cryst. material free of alc. groups, evidently contg. only 1 double bond and possibly consisting of a mixt. of *ergostane*, $C_{27}H_{48}$, and *ergostene*, $C_{27}H_{46}$. The same mixt. seems to be formed by the same reduction of II. G. TOENNIES

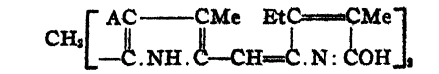
Soy-bean lecithin. II. Lecithins of the α-series. YOSHIKUNI YOKOYAMA AND BUNSUKE SUZUKI. *Proc. Imp. Acad.* (Japan) **7**, 12–4(1931); cf. *C. A.* **25**, 530.—The α-lecithins obtained as double salts with $CdCl_2$ were brominated and fractionated by means of petr. ether, Et_2O and $CHCl_3$; 4 bromides were isolated, the first 3 being oils: *palmito-linoleo-α-lecithin, oleo-linoleo-α-lecithin, dioleo-α-lecithin* and *dilinoleo-α-lecithin*, m. 113–4°; these structures were established by hydrolysis and identification of the fatty acids. C. J. WEST

Neo-, xantho-neobilirubic acid and partial synthesis of mesobilirubin and mesobilirubinogen (urobilinogen). H. FISCHER AND RICHARD HESS. *Z. physiol. Chem.* **194**, 193–228(1931).—Bilirubin, the biol. degradation product of the blood pigment, contains 33 C; its cleavage product, bilirubic acid, obtained by energetic reduction, contains 17 C and represents, therefore, only 0.5 of the bilirubin mol. The other half has hitherto escaped identification. This unknown half of the bilirubin mol., *neobilirubic acid* (I), has now been isolated and identified. The method employed for the cleavage of bilirubin was the resorcinol fusion used by Schumm (*C. A.* **23**, 153)

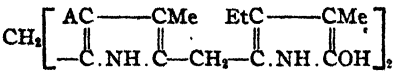


for breaking off the unsatd. side chains of hemin. Bilirubin itself did not give satisfactory results under this treatment, but its hydrogenation product, mesobilirubin, yielded a yellow cryst. product *neoxanthobilirubic acid* (II). The relationship between II and I is that of pigment and leuco compd. The synthesis of mesobilirubin was effected by condensing 2 mols. of II with 1 CH_2O. This supplies the additional C atom of the bilirubic acid half of the mol., the other half being neobilirubic acid itself. *Neoxanthobilirubic acid* (II), m. 229° (*Me ester* m. 190°), was prepd. by adding mesobilirubin to boiling resorcinol, pouring the molten mass into H_2O, extg. the ppt. with $CHCl_3$ and recrystg. from MeOH. It contains a free CH since it yields a cryst. *monoazo dye*, m. 193° (decompn.), with PhN_2Cl. Bromination converts it into a *mono-Br deriv.*, darkens 171° but does not m. below 350°, in which the Br is substituted on a pyrrole nucleus. With $C_6H_4(CO)_2O$ at 180-90° it forms an orange-yellow *phthalide*, m. 298°. On reduction with Na-Hg it yields the leuco compd. I, which gives an intense Ehrlich reaction and on treatment with MeOH at 190° reverts to II. On oxidation it yields methylethylmaleic imide, m. 67°. It contains 1 CH_2 less than xanthobilirubin. The probable formula of II is

While bilirubic acid breaks down into cryptopyrrole and cryptopyrrolecarboxylic acid, a substance of the above structure should yield cryptopyrrole and hemopyrrolecarboxylic acid. Both of these products were actually obtained and identified. The pyrrole ring contains a reactive CH which condenses with aldehydes, 2:1. With BzH the product is *bis(neoxanthobilirubic acid)phenylmethane*, m. 257°, represented by the formula



In the Gmelin reaction this product gives a sequence of colors similar to that of bilirubin. It is the first synthetic product to give this characteristic reaction. When reduced with HI-AcOH it yields *benzylneobilirubic acid*, m. 187°. The other product should be I, but it has not yet been identified. Other aldehydes give similar condensation products with II; *o*-$O_2NC_6H_4CHO$ ⟶ *bis*(II)-*o-nitrophenylmethane*, m. 259°, *p*-$Me_2NC_6H_4CHO$ ⟶ *bis*(II)-*p-dimethylaminophenylmethane*, m. 239°, 4-methyl-3,5-dicarbethoxy-2-formylpyrrole ⟶ *condensation product*, m. 239°, AcH ⟶ *bis*(II)*methylmethane*, m. 267°, CH_2O ⟶ *bis*(II)*methane*, m. 310°. This last product coincides with *mesobilirubin* in cryst. form, m. p., mixed m. p. and Gmelin reaction. It gives the same *Me ester*, m. 190°, which forms the same red *HCl salt*. Both mesobilirubin and the synthetic product are reduced by Na–Hg to the leuco deriv., *mesobilirubinogen*, both give an intense diazo reaction, and with $Zn(OAc)_2$ yield *urobilin*, m. 192°, with its characteristic fluorescence. The crystallographic identity is complete. All of the above aldehyde condensation products are yellow and well crystd. Condensation products were also obtained with MeAc and with camphor. Reduction of II by HI-AcOH or by Na-Hg gives the leuco compd. *neobilirubic acid* (I), m. 185°. This gives a sharp m.-p. depression with bilirubic acid which m. 187°. Like II it contains a free CH and condenses with aldehydes. The condensation product with BzH, m. 248°, is identical with that obtained from mesobilirubin and BzH (Me ester m. 212°). The PhCH deriv. is reduced by HI-AcOH to *benzylneobilirubic acid*, m. 189°. The latter cannot be brominated, but with Br-AcOH it undergoes oxidation to *benzylideneneobilirubic acid*, m. 248°. These 2 substances represent pigment and leuco compd. Bilirubic acid, on the other hand, does not condense with BzH since the pyrrole rings are completely satd. The formula for I is



Reduction of mesobilirubin by HI-AcOH gives both halves, I and bilirubic acid, in 50% yield. They may be sepd. by $CHCl_3$ in which the former is difficultly and the latter easily sol. The condensation products of I and II with aldehydes represent 2 distinct types, similar to those obtained with simple pyrroles, *viz.*, the tripyrrylmethanes and the dipyrrylmethenes. MeAc condenses first to mesityl oxide and

this with II to *bis*(II)*isobutylenemethylmethane*, m. 246°. Mesobilirubin is

and its leuco compd., *urobilirubinogen*,

The main difficulty in explaining the urobilin reaction is the fact that dehydrogenation does not give mesobilirubin. Air oxidation gives, instead, urobilin. Perhaps the formation of urobilin consists in dehydrogenation to a trimethin pigment in which numerous possibilities of isomerism exist. Such a structure would be extremely unstable and inclined to formation of resins. All this confirms the supposition that hemin consists of 4 pyrrole rings which are linked by 4 methin bridges. Hemin contains 34, bilirubin 33 C atoms. A connecting CH group thus steps out and is replaced by 2OH in the opened porphin ring, and the new bis(hydroxypyrro)methin pigment, the hypothetical structure of urobilin but with C_2H_3 in place of Et groups, would then occur as intermediate product in the formation of bile pigment. There still remains, however, the possibility of a more complete breakdown of the blood pigment and a resynthesis to bilirubin from the resulting fragments. A. W. Dox

Condensing hydrocarbons. Imperial Chemical Industries, Ltd. Fr. 694,350, Apr. 23, 1930. Aromatic or unsatd. hydrocarbons are prepd. by passing hydrocarbons contg. at least 2 atoms of C per mol. through a heated space at a temp. of at least 1000° or 1100°, preferably 1200°, and at a volumetric speed of 50 or 100, preferably more. The treatment may be carried out in several steps with removal of aromatic hydrocarbons between the steps, the temp. and speed increasing from step to step. The walls of the reaction chamber may be made of agglomerated SiC or graphite or an alloy resistant to heat. If it is desired to favor the production of $C_{10}H_8$ the walls may be made of sillimanite.

Synthetic hydrocarbons. Henry C. Wade. Fr. 694,924, Mar. 29, 1930. Liquid synthetic hydrocarbon products are prepd. by vaporizing crude petroleum or portions thereof having relatively high b. ps. or liquefied coal or like materials, and during this treatment leading the vapor through a spiral path with speed and without pressure, and through a zone contg. a metallic catalyst at a moment when the hydrocarbon reaches the atomic state and along with steam to produce nascent H and free C which combine. The vapors are condensed or fixed in the state of gas by a suitable heat treatment. An app. is described.

Hydrogenating aromatic hydrocarbons and their derivatives. I. G. Farbenind. A.-G. Brit. 336,583, July 10, 1929. Compds. such as C_6H_6, naphthalene or their hydroxy or amino derivs. are hydrogenated at temps. below 350° in the presence of mixed catalysts immune from poisoning from S and the like and which comprise oxides or hydroxides or sulfides of metals of group 6 of the periodic system in admixt. with

metals of group 8 or heavy metals of group 1 (as such or in the form of their compds.) deposited on carriers of large surface. Examples are given of the use of sulfides of Pt and of W deposited on active silica, oxides of Ni and Mo and $CaCO_3$ deposited on active charcoal, and sulfides of Co and Mo deposited on Florida earth.

Hydrocarbon derivatives. I. G. FARBENIND. A.-G. Fr. 695,095, May 5, 1930. Hydrocarbon derivs. contg. in the mol. more than one halomethyl group are prepd. by the reaction on polynuclear hydrocarbons, of an aq. soln. of CH_2O satd. with hydracids. Examples are given of the prepn. of di(ω-chloromethyl)naphthalene, m. 130–140°; chloromethyl derivs. of $C_{14}H_{10}$ and a product corresponding to $C_{10}H_{10}(CH_2Cl)_2$, m. 117.5°.

Halogenation of paraffin hydrocarbon series. N. V. BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Dutch 23,383, Jan. 15, 1931. For the halogenation of satd. aliphatic hydrocarbons an enameled reaction vessel is used; this prevents both corrosion and C liberation.

Halogenated isocyclic compounds. I. G. FARBENIND. A.-G. Brit. 335,948, April 3, 1929. Isocyclic compds. substituted in the nucleus by Cl or Br or both are prepd. by reaction on isocyclic compds. with HCl or HBr or both in oleum or chlorosulfonic acid or their mixts. in the presence of halogen carriers such as S, I, Sb, As, Bi, Hg or their compds. Temp. conditions may be chosen to avoid or favor side-reactions such as prepn. of halogenated sulfonic acids or halogenated quinones. Among the starting materials which may be treated are benzene, naphthalene, anthracene, pyrene, perylene and their nitro, amino and halogen derivs., benzanthrones, dibenzanthrones, *ms*-benzodianthrones, *ms*-naphthodianthrones, *allo-ms*-naphthodianthrones, *ms*-anthradianthrones, anthanthrones, dibenzopyrenequinones or isomeric compds.

Converting olefins into higher olefins and aromatic hydrocarbons, etc. I. G. FARBENIND. A.-G. Brit. 336,234, May 4, 1929. Starting materials such as C_2H_4, C_3H_6, C_4H_8 or gas mixts. contg. them such as casing head gases or gases produced in cracking mineral or tar oils are brought into contact with elementary Si or a Si-contg. material such as ferro-Si contg. a large proportion of Si, in the form of small pieces or bricks (suitably at 350–800° and under pressures which may be up to 1000 atm. or more). App. is preferably used which resists H_2S and which does not cause deposition of C, such as "V2A" steel or steels contg. Mo and W. Various details and examples are given.

Separating olefins. N. V. BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 694,323, Apr. 23, 1930. The concn. of one constituent of a fluid mixt. is increased by effecting the fractionated distn. of the mixt. in the presence of a solvent having a selective attraction toward one of the constituents. Thus, to sep. a mixt. of olefin hydrocarbons and paraffins NH_3 is added. An example is given of the sepn. of butylene and butane.

Oxidation products from hydrocarbons, waxes, etc. I. G. FARBENIND. A.-G. Brit. 337,130, Sept. 12, 1929. An app. is described for producing oxidation products from solid or liquid hydrocarbons, waxes and the like by the action of oxidizing gases, in which cooling liquid is sprayed on the outer surface of the reaction vessel which is surrounded by a pressure-tight cooling jacket.

Oxygenated organic compounds from carbon oxides and hydrogen by catalytic reactions. H. DREYFUS. Brit. 337,014, July 24, 1929. Compds. such as EtOH, HOAc, acetaldehyde, MeOAc and higher homologs are made by use of catalysts comprising ferrites, ferrates, cobaltites or cobaltates such as those of alkali or alk. earth metals or of Al, preferably at temps. of 200–600° (suitably 250–350°) under 50–500 atm. or higher pressure. There may be used coke-oven gases, producer gas or water gas which may be preliminarily treated if desired to effect formation of synthetic products such as MeOH or EtOH in the presence of a catalyst such as ZnO or a basic chromate. The catalysts may be used in connection with Zn, Mg, Ca, Al, Cr, Mo, V, W or U or their oxides or other compds. Cu may be present, and the app. used may be of Cu or steel lined with Cu or of steel contg. Mo, W, Co or Ni.

Organic bases. I. G. FARBENIND. A.-M. (Otto Nicodemus and Walter Schmidt, inventors). Ger. 516,765, Sept. 27, 1928. Addn. to 479,351 (*C. A.* **23**, 4709). Org. bases, generally of the pyridine series, are prepd. by passing C_2H_2 and the vapor of an aliphatic primary or secondary amine at 250–400° over a catalyst comprising an inorg. or org. salt capable of combining with NH_3, or a metal oxide such as Fe_2O_3, ZnO or Al_2O_3. Examples are given.

Organic isocolloids. LASZLÓ AUER and LAJOS SUSZTEK. Fr. 694,339, Apr. 23, 1930. The phys. properties of org. isocolloids composed of unsatd. org. acids of high mol. wt. or contg. such acids, are modified by incorporating therein, by soln. or dispersion, soaps of alkali or alk. earth metals, Zn, Mg, etc., and heating to a relatively

low temp. The treated products may be vulcanized. Examples are given in which linseed oil, K or Na soap and linseed oil acids are heated to about 200°. An after treatment with S gives products which are useful *in varnish and rubber manuf.* Cf. *C. A.* **25**, 618.

Organic isocolloids. LASZLÖ AUER. Fr. 694,340, Apr. 23, 1930. The soly. of modified or unmodified org. isocolloid substances is altered by dissolving or dispersing in such substances, agents favoring soln., *i. e.*, agents which are themselves sol. in the solvent in which it is desired to render the isocolloid sol. or more sol. Thus, castor oil is heated with NH_4I *in vacuo* for 5 hrs. at 260° to give a dark colored soft paste which is sol. in acetone. Other examples are given.

Organoarsenic compounds. I. G. FARBENIND. A.-G. Brit. 337,299, Feb. 11, 1929. *N*-Alkyl-, -aralkyl-, or -alkylene-3,4-benzimidazolonearsonic acids are prepd. by treating *o*-aminoalkylamino-, *o*-aminoaralkylamino- or *o*-aminoalkyleneamino-benzenearsonic acids with a chloroformic acid ester and decompg. the product with an acid (preferably with heating). Details are given of the production of 1-methyl-, 1-propyl- and 1-allyl-2,3-dihydro-2-ketobenzimidazole-5-arsonic acids by interaction with Et chloroformate of 4-methylamino-, 4-propylamino- and 4-allylamino-3-amino-benzenearsonic acids, resp.

Separating organic liquids. GENERAL TECHNICAL CO., LTD. Fr. 695,005, Aug. 2, 1929. The constituents of mixts. of org. liquids of different b. ps. are sepd. by passing the mixts. through a tube or tubes, preferably filled with contact material, a counter-current of vapors, of a non-miscible liquid being circulated, the temp. of treatment being slightly higher than the b. p. of the non-miscible liquid. An example is given of the sepn. of a mixt. of hydrocarbons using a counter-current of steam.

Catalysts for reducing or dehydrogenating organic compounds. I. G. FARBENIND. A.-G. (Hellmut Langheinrich, inventor). Ger. 516,251, May 7, 1926. Oxygenated compds. of Mo or W are treated with NH_3 (or gases contg. NH_3) at 450–600° and at atm. or raised pressure. The compds. obtained from molybdates or tungstates of Cu, Ag, Fe and Ni are particularly suitable. Examples are given.

Alcohols. I. G. FARBENIND. A.-G. Fr. 694,424, Apr. 25, 1930. Alcs. are prepd. by treating sugars with H in the presence of catalysts other than Pt and in the presence of OH ions. Examples are given of the prepn. of sorbitol and mannitol from glucose in the presence of activated Ni and CaO, etc.

Alcoholates. CHRISTIAAN VAN LOON. Ger. 513,677, July 22, 1926. Alkali metal alcoholates of polyhydric alcs. are prepd. by evapg. aq. solns. of the alc. and an alkali hydroxide at high temp. and reduced pressure. The reaction is preferably carried out in a current of indifferent gas. Thus, a soln. contg. 1 mol. glycol and 1 mol. concd. NaOH is evapd. in a water bath *in vacuo*. The product contains 26.2% Na. Other examples are given.

Phenolic aldehydes. SCHIMMEL & CO. A.-G. Ger. 513,678, Oct. 18, 1925. The ozonides of the corresponding propenyl compds. are reduced by hyposulfite. Thus, isoeugenol in $CHCl_3$ is satd. with O_3, and the resulting ozonide treated with $Na_2S_2O_4$ to give an 84% yield of vanillin. Other examples are given.

Esters. I. G. FARBENIND. A.-G. (Erwin Schwabe, inventor). Ger. 516,135, Aug. 6, 1925. In the manuf. of esters from acids that are relatively non-volatile and alcs. that are insol. or difficultly sol. in water, a reaction mixt. is used contg. only a small excess, if any, of acid or alc. and also contg. a water-insol. solvent for the alc., preferably a solvent b. near 100°. The distillate obtained from the mixt. seps. into 2 layers, the aq. layer being removed and the layer of solvent and unreacted alc. being returned to the reaction vessel. The prepn. of isobutyl phthalate with the use of toluene as the solvent is described in an example. Cf. *C. A.* **24**, 2141.

Esters of carbonic acid. I. G. FARBENIND. A.-G. (Gerhard Steimmig and Max Wittwer, inventors). Ger. 516,281, Nov. 15, 1928. Carbonic esters of glycols are prepd. by treating α, β- chlorohydrins with alkali carbonates or bicarbonates. Thus, glycol carbonate, $CH_2OC(O)OCH_2$, may be prepd. by warming ethylenechlorohydrin 1 mol. with $NaHCO_3$ 1 mol. for a few hrs. while stirring. Other examples are given also.

Esters such as fatty acid glycerides. I. G. FARBENIND. A.-G. Brit. 336,276, July 4, 1929. In the production of esters of polyhydric alcs. such as glycerol with acids such as those of linseed or olive oil, the component of lower b. p. is led in vapor or mist form (and suitably with a carrier gas such as H, for simultaneous hydrogenation, N or H_2O vapor) at reduced pressure into the liquid higher-boiling component at a temp. above the b. p. of the lower-boiling component, and catalysts may be used such as Mg oleate, H_3PO_4 or $ZnCl_2$. Cf. *C. A.* **25**, 115.

Vinyl ethers. I. G. FARBENIND. A.-G. (Otto Ernst and Walter Berndt, inventors). Ger. 513,679, May 24, 1927. Vinyl ethers of aromatic hydroxy compds. of a phenolic character, without substituents with OH groups linked to aliphatic residues, are obtained by treating the aromatic compds. with vinyl halides, especially the chloride, in the presence of bases and, optionally, catalysts. Thus, PhOH, NaOH, water and vinyl chloride are fused together at 180–200° to give an 80% yield of vinyl phenyl ether of sp. gr. 0.977 (20°) and b. 155-6°. Other examples are given. Cf. *C. A.* **25**, 302.

Ethers of α-naphthylmethyl alcohol. I. G. FARBENIND. A.-G. (Gustav Reddelien and Hans Lange, inventors). Ger. 516,280, Apr. 3, 1929. α-(Chloromethyl)naphthalene is treated with aliphatic or aromatic alcs. in the presence of an acid-binding agent. Examples are given of the prepn. of *methyl α-naphthylmethyl ether*, b_{11} 134°, *ethyl α-naphthylmethyl ether*, b_{11} 144.5°, *butyl α-naphthylmethyl ether*, b_{11} 167°, and *benzyl α-naphthylmethyl ether*, b_{11} 220°. Cf. Ger. 508,890 (*C. A.* **25**, 716).

Hydrogenating phenols. I. G. FARBENIND. A.-G. Brit. 336,616, April 17, 1929. Hydroaromatic hydrocarbons are prepd. from phenols by hydrogenation at temps. of 250-400° under pressures above 50 atm. with catalysts comprising oxides or sulfides of metals of the second to seventh periodic groups (preferably those of the sixth group) in admixt. with Cu, Ag, Au or metals of the eighth group or their oxides or sulfides. Numerous details and examples are given.

Dioxanes. I. G. FARBENIND. A.-G. Ger. 516,844, Dec. 28, 1927. Addn. to 500,223 (*C. A.* **24**, 4307). Single or mixed homologs of dioxane or mixts. of dioxane therewith are prepd. as described in Ger. 500,223, using as initial materials the mixts. of glycols obtainable from cracking gases, the by-products obtained in etherifying such mixts., or the single higher glycols isolated from the mixts. Examples are given. Cf. *C. A.* **25**, 524.

Indanones. I. G. FARBENIND. A.-G. (Fritz Mayer, inventor). Ger. 515,110, June 11, 1927. Addn. to 513,204 (*C. A.* **25**, 1260). Indanones are prepd. from xylenes, halotoluenes or dihalobenzenes by condensing these with a halide of β-chloropropionic acid, and treating the resulting ketone as described in Ger. 513,204. Thus, *7-methyl-6-chloro-3-indanone*, b_{14} 188°, is obtained from *o*-chlorotoluene. Other examples are given also.

Naphthenates of alkaline earth and heavy metals. I. G. FARBENIND. A.-G. Brit. 335,863, Feb. 22, 1929. In the prepn. of naphthenates such as those of Co, Pb, Mn, Zn, Ca, Pb-Mn or Co-Zn, naphthenic acid is saponified with KOH and the resulting soln. is treated with a suitable alk. earth or heavy metal salt (all operations being carried out at boiling temp.) and the ppt. thus formed may then be dried at 130° in the same vessel.

Dialkyl sulfates. ÉTABLISSEMENTS LAMBIOTTE FRÈRES. Brit. 336,681, June 25, 1929. For making dialkyl sulfates, the corresponding ether (derived from the alc. such as MeOH or PrOH and H_2SO_4) is caused to react with oleum, preferably in theoretical proportions and at temps. below 50° (suitably 30°). Various details of procedure are given.

Sulfonamides. IMPERIAL CHEMICAL INDUSTRIES, LTD., N. BENNETT, H. DODD and W. C. SPRENT. Brit. 336,512, Jan. 17, 1930. Monoalkylxylenesulfonamides are made by direct alkylation of xylenesulfonamide with MeCl or EtCl under pressure in the presence of caustic alkali. Various details of procedure are given.

Alkali salts of aromatic sulfohaloamides. CHEM. FAB. VON HEYDEN A.-G. (Curt Philipp, inventor). Ger. 515,465, June 20, 1928. Addn. to 514,094 (*C. A.* **25**, 1261). The reagents necessary for the method of Ger. 514,094 are mixed in the dry state, and made into tablets if desired. The reaction is effected by dissolving the mixt. in water. One mol. of the alkali may be dispensed with by using the sulfonamide in the form of its monosodium salt.

Aluminum gluconates. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 336,922, Feb. 15, 1929. Sol. Al compds. forming stable solns. are obtained by reaction of Al compds. such as the sulfate with gluconic acid or its salts such as alk. earth metal gluconates (preferably in the presence of alk. earth metal hydroxides). The product may be evapd. to dryness or pptd. with alc. and the acid salts obtained may be neutralized with NH_3 or other alkali, or a neutral salt may be obtained directly by reaction of an alkali aluminate soln. with gluconic acid. Cf. *C. A.* **24**, 5437.

Lead alkyl compounds. STANDARD OIL CO. OF ILL. Ger. 505,688, Aug. 27, 1926. A Pb-Na alloy is heated with the desired dialkyl sulfate with free halogen or a metal halide as a catalyzer. Thus a Pb-Na alloy contg. 10% Na is heated with $(Et)_2SO_4$ in toluene with KI in water as the catalyst, to give $Pb(Et)_4$ on distn.

Metal carbamates. I. G. FARBENIND. A.-G. Brit. 336,749, Sept. 19, 1929. Reaction is effected between NH_4 carbamate and finely divided (preferably dry) metal oxides such as those of Zn, Mg or alk. earth metals, in the absence of solvents, at temps. not usually substantially above 100° (suitably about 60–80° in most cases), and if desired in the presence of a stream of an inert gas such as NH_3, air or N. The alk. earth metal carbamates thus produced may be converted into cyanamides by heating to about 700° and treating with a stream of NH_3.

Pyrazolone derivatives. I. G. FARBENIND. A.-G. (Hans Grotowsky, inventor). Ger. 515,782, Apr. 5, 1927. Addn. to 514,421 (*C. A.* 25, 1684). The method of Ger. 514,421 is modified by using, instead of a prepd. benzylidene imine or a stoichiometric mixt. of the corresponding aldehyde and amine, a mixt. contg. a substantially lower proportion of the amine. Examples are given.

Triazine derivatives. I. G. FARBENIND. A.-G. Fr. 694,756, Apr. 30, 1930. See Brit. 334,887 (*C. A.* 25, 1266).

Hexahydrodiphenylamine compounds. I. G. FARBENIND. A.-G. Brit. 337,103. Aug. 21, 1929. Two- or three-nuclear condensation products, obtained as described in Brit. 313,421 (*C. A.* 24, 1123) from cyclohexanone or its alkyl derivs. and aromatic amines or their products of acylation, are subjected to catalytic hydrogenation under pressure (with a base metal catalyst such as Ni and preferably in the presence of a diluent such as decahydronaphthalene). Details are given of the production of 4-aminohexahydrobiphenyl from 4-aminotetrahydrobiphenyl, 4-amino-3-methylhexahydrobiphenyl from 4-amino-3-methyltetrahydrobiphenyl and of similar reactions, and catalysts are described contg. Ni, Co, Ce, Bi and Cu in various mixts. which may be carried on pumice or silica gel.

Condensation products. I. G. FARBENIND. A.-G. (Arthur Lüttringhaus, Heinrick Neresheimer and Wilhelm Schneider, inventors). Ger. 513,530, Feb. 23, 1926. Addn. to 487,870 (*C. A.* 24, 1867). Condensation products are obtained by converting benzanthrone, or derivs. with a free or halogenated *Bz*-1-position, or derivs. with S- or O-contg. substituents into the corresponding ketohalides and then condensing these with other benzanthrone ketohalides, benzanthrone or derivs. Thus, benzanthrone in $PhNO_2$ is treated with PCl_5 and concd. H_2SO_4. The benzanthrone ketochloride obtained is then condensed with benzanthrone in $C_6H_3Cl_3$. Other examples are given. Cf. *C. A.* 25, 1263.

Condensation products. HENKEL & CIE. G. M. B. H. Ger. 513,797, Oct. 14, 1927. In condensing polyhydric alcs. and their ketonic derivs. with aliphatic, aromatic, mixed or hydroaromatic ketones, by heating to a high temp., the reaction is carried out without addn. of solvents, and in the presence of a small quantity of aq. or gaseous mineral acid or acid salt. Examples describe the condensation of glycerol with cyclohexanone and methylcyclohexanone. Cf. *C. A.* 24, 5044.

Halogenated fatty acids. I. G. FARBENIND. A.-G. Brit. 336,623, July 15, 1929. Satd. or unsatd. fatty acids contg. more than 8 C atoms per mol. and which may contain OH groups are treated with halogens or with a mixt. of a chlorate and HCl to introduce at least 3 halogen atoms per mol. one at least of which replaces a H atom by substitution. Examples are given of the production of trichlorinated, tetrabrominated and hexachlorinated ricinoleic acid, trichlorinated oleic acid, pentachlorodihydroxy stearic acid, heptachlorinated ricinoleic acid, tetrachlorinated oleic acid and hexa chlorinated stearic acid, etc. The products are oils, usually having adhesive properties, or plastic or resinous materials. Cf. *C. A.* 24, 3517.

Aromatic dicarboxylic acids. RÜTGERSWERKE A.-G. (Johannes Sielisch and Ernst Guttman, inventors). Ger. 516,282, May 5, 1929. The oxidation of aromatic *o*-diketones to dicarboxylic acids, *e. g.*, the oxidation of phenanthraquinone to diphenic acid, is effected in aq. alk. suspension with H_2O_2, or in aq. suspension with Na_2O_2 or like metal peroxide. An addn. of MeOH or EtOH accelerates the reaction. Examples are given.

Sulfonic acids of the fatty series. H. TH. BÖHME A.-G. Fr. 694,692, Apr. 30, 1930. Sulfonic compds. of higher fatty acids and their alkali salts are prepd. by treating the corresponding α-bromo fatty acids with an alkali sulfite. Thus brominated lauric acid is dissolved in aq. NH_3 and the soln. is boiled under reflux with a concd. aq. soln. of $(NH_4)_2SO_3$, giving the NH_4 salt of the α-sulfolauric acid. The products are wetting, purifying, emulsifying and foaming agents.

Sulfonic acids, naphthenic acids, etc. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 694,578, Apr. 26, 1930. Purified sulfonic, naphthenic and like acids are prepd. by dissolving the initial material in water and treating with an amt. of tar oil, etc., sufficient to permit the substances to be purified, to sep. with the tar oil, after

which the aq. soln. is decanted and the tar oil is removed from the purified products by distn. Cf. *C. A.* **24**, 629.

Aliphatic acids and esters such as acetic acid and methyl acetate. BRITISH CELANESE, LTD., and W. BADER. Brit. 337,053, July 27, 1929. MeOH or other liquid aliphatic alc. is mixed with one or more acid catalysts such as H_3PO_4 and the mixt. is subjected to the action of CO at 200–450° and at pressures up to 300 atm. Esters in the reaction products may be saponified with H_2O in the presence of H_2SO_4 (or, preferably, H_3PO_4) at 150–300° to produce an acid and an ether. App. and various details of procedure are described.

Concentrating acetic acid. MARTIN MUGDAN and JOSEF WIMMER (to Consortium Elektrochemische Industrie, G. m. b. H.). U. S. 1,792,113, Feb. 10. See Fr. 671,283 (*C. A.* **24**, 2143).

Concentrating aqueous solutions of formic and acetic acids. JAMES NELSON, LTD. Ger. 513,574, July 13, 1927. See Brit. 281,827 (*C. A.* **22**, 3669).

Acetic and formic acid. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,016, Apr. 16, 1930. Aq. solns. of AcOH or HCOOH are concd. by passing the vapors thereof over active C at a temp. of 120–130°, whereby the acid is absorbed in preference. The absorbed acid is sepd. from the C by raising the temp. and reducing the pressure.

Carboxylic acid chlorides. FRANZ HENLE (to I. G. Farbenind. A.-G.). U. S. 1,792,163, Feb. 10. In prepg. carboxylic acid chlorides such as acetyl chloride, chloroacetyl chloride, propionyl chloride or butyryl chloride by reaction of the corresponding free acids with sulfochloride compds. such as Na chlorosulfonate or *p*-toluenesulfochloride, the reaction is rendered more efficient and almost quant. yields are obtained by adding to the reaction mixt. a "solid extender" such as NaCl, and other substances may be added such as a neutral sulfate, a pyrosulfate, kaolin or sand. Several examples with details of procedure are given.

Acetic anhydride and other aliphatic anhydrides. H. DREYFUS. Brit. 336,960, July 22, 1929. For producing the anhydride, the vapor of the corresponding acid is contacted with an oxide or acid of As or Sb or a salt of such an acid such as arsenates or antimonates of Na or K or Mg arsenate, which may be placed in tubes on a carrier. Various details and modifications of procedure are described.

Ethylene from acetylene. I. G. FARBENIND. A.-G. Brit. 336,999, May 24, 1929. Te or a compact form of Ni is used as catalyst in forming C_2H_4 by hydrogenation of C_2H_2. The Te may be used either in compact form or distributed on a carrier. Cf. *C. A.* **24**, 4523.

Absorbing ethylene in sulfuric acid. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 336,603, June 4, 1929. Various compds. of Os, Ir, Pt, Ru, Rh, Pd, Cu, Fe, Co or Ni are used in the H_2SO_4 as catalysts in absorbing C_2H_4 or treating crude gases contg. C_2H_4 such as natural gas or cracking gases, to obtain a soln. which may be hydrolyzed, distd. or otherwise treated for the production of esters, alcs., ethers, etc. Various compds. of the catalytic metals may be added to the soln. and then converted into sol. complex compds. by passing CO or nitric oxide through the soln. Solvents such as EtOH, HOAc, $PhNO_2$ or ether may be added to the H_2SO_4 and froth-forming or emulsifying agents also may be added. Brit. 336,604 relates to a process of generally similar character for the absorption of olefins contg. more than 2 C atoms such as propylene or diallyl or crude gases contg. these or similar compds. Various details and modifications of procedure and examples are given.

Absorbing ethylene in sulfuric acid. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 336,633, June 4, 1929. The absorption is catalyzed by the presence of one or more of the metals Pt, Pd, Os, Ir, Ru or Rh or their compds., in finely divided form and preferably on a carrier such as carbon black, silica gel or decolorizing clay (suitably in the form of a colloidal ppt.).

Dichloroethylene. CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE G. M. B. H. Fr. 694,054, Apr. 16, 1930. Dichloroethylene is prepd. by passing trichloroethane over heated catalysts composed of salts of heavy metals such as Fe or Cu, or alk. earth compds. such as $BaCl_2$.

Oxidizing propylene. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,726, Apr. 29, 1930. Isopropyl alc. and isopropyl acetate are obtained by absorbing propylene in a mixt. of concd. H_2SO_4 and glacial AcOH and hydrolyzing the sulfuric esters formed.

Methanol. H. DREYFUS. Brit. 335,962, June 5, 1929. In synthesizing MeOH from CO and H, the reaction gases are passed first over one or more masses of ZnO with or without Cr oxide and then over one or more MeOH catalysts which are sensitive to S poisoning such as catalysts contg. Cu or Mn or their compds. Various details of procedure are described and water gas may be used as an initial material.

Methanol synthesis. ALWIN MITTASCH, MATHIAS PIER and CARL MÜLLER (to I. G. Farbenind. A.-G.). U. S. 1,791,568, Feb. 10. In synthesis of MeOH from H and C oxides in the presence of a catalyst such as potash-lime or potash-alumina more than 2 vols. of H for each vol. of CO and more than 3 vols. of H for each vol. of CO_2 are employed. Several examples are given. Cf. *C. A.* **25**, 715.

Butanol and higher alcohols. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 336,811, Feb. 17, 1930. For producing BuOH and higher alcs., EtOH vapor under pressure (preferably 130–300 atm.) is heated to not over 400° (preferably not much over 325°) in the presence of a catalytic mass contg. MgO together with a smaller quantity of Cu oxide.

Tetrahydrofurfuryl alcohol. E. I. DU PONT DE NEMOURS & CO. and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 337,296, Jan. 25, 1930. Furfural is heated under pressure in the presence of H, a Ni catalyst and water (suitably at 50–150° and under 100 lbs. per sq. in. pressure). The catalyst is preferably prepd. by pptg. a soln. of Ni nitrate with $(NH_4)_2Cr_2O_7$ and NH_3 and partially reducing the ppt. with H at 500–550°.

Formaldehyde. BAKELITE CORP. Brit. 336,282, July 10, 1929. In the catalytic oxidation of MeOH, formation of by-products is restricted by adding a basic agent such as NH_3, to the reaction mixt. at any stage of the process prior to the distn. of the crude product obtained by absorbing or condensing the mixt. leaving the catalyzers, so that the distillate is rendered substantially neutral. Brit. 336,283 relates to the inhibiting of by-product formation in similar processes by rapidly cooling the hot gaseous product leaving the catalyzers by bringing it into contact with an aq. liquid (preferably so proportioned that the temp. of the liquid does not exceed 50°) and the concn. of the formaldehyde is kept substantially below 30%. Various details of procedure are described. Cf. *C. A.* **24**, 866.

Acetaldehyde. GUTEHOFFNUNGSHÜTTE OBERHAUSEN A.-G. Fr. 694,382, Apr. 24, 1930. AcH is prepd. by passing CH_4 and CO_2 through an elec. field produced by elec. currents of high frequency and tension. Contact substances may be placed in the field.

Urea. A. B. LAMB. Brit. 335,913, June 27, 1929. In a cyclic process, liquid NH_3 and liquid CO_2 are continuously and separately introduced into a heated autoclave maintained under pressure, and the melt contg. urea is continuously withdrawn from the autoclave, unconverted NH_3 and CO_2 are sepd. from the melt by distn. and are sepd. from each other, and after being dried, compressed and liquefied they are reintroduced in liquid form into the autoclave. Various details of app. and procedure are described and producer gas (with conversion of its CO into CO_2) may be used as a starting material (the NH_3 being produced by catalytic synthesis from N and H). Cf. *C. A.* **25**, 305.

Thiourea. I. G. FARBENIND. A.-G. Brit. 336, 111, Oct. 19, 1929. Ca cyanamide is treated with H_2S in the absence of liquids or in the presence of small quantities of liquids sufficient to form a paste (such as water or MeOH, EtOH, aniline, alkyl amines, EtOAc or other esters, pyridine or hydrocarbons such as C_6H_6 or their halogen derivs.) and in some cases alk. substances such as NH_3 and gaseous amines are added. The materials may be subjected to high pressures and to stirring and the temp. usually should not exceed 100°. The thiourea is extd. from the reaction mixt. by a selective solvent such as acetone, pyridine or its homologs, mixts. of alcs. and ethers or of alc. and C_6H_6 or of alcs. and $CHCl_3$, CCl_4 or C_6H_6, or in some cases by aq. mixts. such as aq. alcs. Various details of procedure are described. Cf. *C. A.* **24**, 4524.

5-Halo-2-amino-1-alkoxy- and -1-aralkyloxybenzenes and intermediates. WILHELM FITZKY (to General Aniline Works). U. S. 1,792,156, Feb. 10. By the gradual addn. of halogenating agents such as SO_2Cl_2 or Br, sufficient for the introduction of 2 halogen atoms, to suspensions (suitably in $C_2H_2Cl_4$ or $PhNO_2$) of *o,o'*-dialkoxy- and *o,o'*-diaralkyloxydiphenylureas (obtainable by causing the corresponding amino compds. to react with phosgene in the presence of an acid-binding agent) there are formed dihalogen compds. of the general formula 4,2-X(RO)C_6H_3NHCONHC_6H_3(OR)X-2,4 wherein R stands for alkyl or aralkyl and X stands for halogen. These compds., when split up by means of a caustic alkali or NH_4OH are converted into 5-halo-2-amino-1-alkoxy- and -1-aralkyloxybenzenes such as 5-chloro-2-amino-1-methoxybenzene, m. about 52°, 5-bromo-2-amino-1-methoxybenzene, m. 60–1°, 5-chloro-2-amino-1-ethoxybenzene, m. 32°, 5-chloro-2-amino-1-butoxybenzene, b_{12} 160°, and 5-chloro-2-amino-1-benzyloxybenzene, m. 46–7°. Details of procedure for making all these compds. are given.

1-Phenyl-2-methylamino-1-propanol (ephedrine). KNOLL A.-G. CHEMISCHE FABRIKEN and W. KLAVEHN. Brit. 336,412, July 30, 1929. 1-Phenyl-1,2-propane-

dione (acetylbenzoyl) is treated with a reducing agent (suitably activated Al in the presence of water) in the presence of methylamine.

Flavanthrone, etc. W. SMITH, L. J. HOOLEY, J. THOMAS and SCOTTISH DYES, LTD. Brit. 336,983, April 16, 1929. 1,1′-Dianthraquinonyls contg. Cl, Br or sulfonic groups in the 2,2′-positions are condensed with substances contg. reactive H atoms such as NH_3, monomethylamine, aniline, aminoanthraquinones, phenols, mercaptans or Na phenate or similar compds. When NH_3 is used condensation is followed by ring closure of the 2,2′-diamino-1,1′-dianthraquinonyl to form flavanthrone. Various examples are given.

4,10-Diaminoperylene. F. BENSA. Brit. 336,144, Dec. 22, 1928. See Fr. 686,233 (*C. A.* **25**, 525).

Isatin and its derivatives. GEORG KRÄNZLEIN, ARTHUR WOLFRAM and EMIL HAUSDÖRFER (to General Aniline Works). U. S. 1,792,170, Feb. 10. Cyanoformarylides of the general formula RNHCOCN in which R stands for a substituted or unsubstituted aromatic residue having at least one free *o*-position to the imino group are transformed into isatins by ring closure with a condensing metal chloride such as $AlCl_3$ or $ZnCl_2$. Examples are given of the treatment of cyanoformanilide; cyanoform(2-methyl-3-chloroanilide) (yielding 6-chloro-7-methylisatin); cyanoform(3,5-dichloroanilide) (yielding the 4,6-dichloroisatin); *N*-cyanoformyl(β-naphthylamine) (yielding a 2,1-naphthisatin, m. 248°); cyanoform(3,5-dimethylanilide) (yielding 4,6-dimethylisatin); and *N*-cyanoformyl(1-chloro-2-naphthylamine) (yielding 1-chloro-2,3-naphthisatin, m. 262°).

Benzyl chloride. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,429, Apr. 25, 1930. $C_6H_5CH_2Cl$ is obtained by treating the crude liquids from the manuf. of benzyl cellulose with HCl. The liquids are given a preliminary treatment with an alk. substance such as Na_2CO_3 to remove Fe or other metals. After removal of $C_6H_5CH_2Cl$ the residue is treated with Cl to give a mixt. of $C_6H_5CH_2Cl$ and BzH.

Vinyl chloride. I. G. FARBENIND. A.-G. Fr. 694,575, Apr. 26, 1930. Vinyl chloride is prepd. by treating ethylene chloride with KOH dissolved in MeOH.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Studies in the physical chemistry of muscle globulin. II. Some physico-chemical properties of muscle globulin [myosin]. JOHN T. EDSALL. *J Biol. Chem.* **89**, 289 313(1930); cf. *C. A.* **22**, 2174.—The muscle globulin is prepd. by extg. fresh, finely ground muscle with an excess of a 1.2 *M* KCl soln. buffered with K_2HPO_4 and KH_2PO_4. The soln. should have an ionic strength of 1.2 to 1.5 and p_H 5.1 to 5.5. The protein is collected and purified by changing the ionic strength of the ext. several times, thus causing either a redissolving or repptn. When pptd., muscle globulin settles out as micellar particles which conc. to a thick jelly-like mass on centrifugation. The pptd. protein has its isoelec. point at p_H 5.1 to 5.5 and between p_H 6.2 and 6.6 is the zone of minimal acid- and base-binding capacity. Myosin is almost completely insol. in the absence of salts or even in the presence of salts at low ionic strengths. As the phosphate soln. approaches p_H 7.4 there is a sudden rise in soly. between ionic strength 0.25 and 0.30. Myosin can be sepd. from serum globulin by pptn. in dil. salt solns. Myosin requires greater concns. of neutral salts to ppt. it than pptd. fibrinogen but somewhat less than is needed by euglobulin. At p_H 7 and 0° it is completely pptd. by 4.4 to 4.6 *M* NaCl. Increasing the temp. decreases the soly. of myosin in concd. salt solns. In the absence of salts myosin is insol. from p_H 4.5 to 8 and at all salt concns. it is insol. from p_H 5 to 6. In moderate salt concns. it is sol. if the p_H is alk. to 6.0 and as the acidity becomes greater than p_H 5 the protein dissolves without the presence of a neutral salt. Alk. to p_H 10, it is also sol. in the absence of salt. The viscosity of myosin is of a higher order of magnitude than that of the blood proteins of myogen. Even concd. ppts. of proteins contain 98 to 99% H_2O and this H_2O can not be removed unless the protein is denatured in the process. In the nearly complete absence of salt, and in the presence of small quantities of alkali, gels of the protein of a peculiar character are formed. Finally myosin is compared to the proteins studied by other investigators. J. R. ADAMS

Studies in the physical chemistry of muscle globulin. III. The anisotropy of myosin and the angle of isocline. ALEXANDER L. VON MURALT AND JOHN T. EDSALL. *J. Biol. Chem.* 89, 315–50(1930); cf. *C. A.* 22, 2174 and preceding abstract.—Highly anisotropic protein in myosin produces double refraction of flow. This is brought about through the orientation and elastic deformation of these particles. The app. for the detn. of the angle of isocline and the double refraction is described. The age of the myosin has no effect on the angle of isocline. For intermediate and high concns. at low temp. it is between 77.5° and 78.5° and approaches 45° as a lower limit with increasing diln. For const. temp. and varying concn. or const. concn. and varying temp. characteristic curves are obtained for the relation between the angle of isocline and angular velocity. Myosin soln. possesses rigidity which is not affected by age. The gel formed from myosin is a thixotropic gel and gives two different crosses of isocline, one with an angle of 45° and the other 61° to 63°. The measurements of angle of isocline have been interpreted as an indication that the myosin particles are of uniform shape and size. **IV. The anisotropy of myosin and double refraction of flow.** *Ibid* 351–86.—A description is given of the app. used to prove that myosin solns. contain anisotropic particles and that anisotropy is connected with the chem. structure of the protein. Double refraction and angular velocity are found to be related by characteristic curves, which vary with protein concn., are reproducible for any given prepn. over a period of time and there appears to be no aging effect. The general form of these curves is the same for all prepns. examd. Denaturing agents produce rapid and complete destruction of the double refraction of flow. Double refraction is ascribed primarily to the orientation of anisotropic protein particles, due to the shearing stresses which arise during flow. Three tentative hypotheses are suggested to explain the observed facts. The Gans effect also indicates that the protein particle is anisotropic. The evidence also indicates that the anisotropic protein particles are of uniform size and shape. The properties of myosin solns. suggest that they may contain rod-shaped particles. The double refraction of myosin would indicate its probable location in the anisotropic disk of the cross-striated muscle fiber, and its general physicochem. properties suggest that it may play a part in the functional activity of the muscle. J. R. A.

Light and catalase. H. KOEPPE. *Strahlentherap.* 34, 598–604(1929).—Blood catalase is regarded as storing radiant energy. B. C. A.

Micellar modifications of human serum by weak electrolytes. P. PONTHUS *Compt. rend. soc. biol.* 103, 1140–2(1930); cf. *C. A.* 24, 4813.—The effect of weak electrolytes on human serum is analogous to that obtained by strong electrolytes, acids or neutral salts. As the acidity increases, micellar vol., as measured by the viscosity of the serum, increases to a max. value and then diminishes. With an increased content of bile salts in serum, the micellar vol. as shown by decreased viscosity constantly decreases. The cond. of the serum increases constantly with increased acidity, but remains const. when the concn. of the bile salts in the serum varies. B. C. B.

The mechanism of the acidification of tissue culture medium. M. MAGATH *Compt. rend. soc. biol.* 103, 1180–1(1930).—The decrease in p_H in tissue culture media from approx. p_H 8.0 to p_H 7.0 is explained by glucolysis. CO_2 accumulates as a result of the action of lactic acid on bicarbonates. Carrel's method for regulating the p_H of tissue culture by controlling the CO_2 content of the air around the tissues works satisfactorily. B. C. BRUNSTETTER

Nucleic acid. I. Enzymes which split nucleic acid. YUTAKA JONO. *Acta Schol. Med. Univ. Imp. Kioto* 13, 162–75(1930).—The leaves and roots of green vegetables and seeds, in general are richer in nuclease than are the fruits. A study of the P:N ratio shows that the base-sugar compds. are more difficultly broken down than are the phosphoric acid-sugar compds. Nucleic acid is rapidly attacked by plant nucleases, the hydrolysis reaching a max. in 3 to 4 days and continuing at an almost const. rate Plant nucleases split yeast nucleic acid about 3 to 5 times as readily as they do thymus nucleic acid. The optimal p_H for the reaction is 6.2 while a rapid decline in decompn occurs in weakly alk. medium. The relationship between the setting free of purine bases and of phosphoric acid remains const. at different p_H values. The nucleases are stable in acid or alk. medium and are more or less completely adsorbed by fuller's earth or kaolin. The reaction does not influence the completeness of this process. Animal nucleases were shown to be present in almost every organ but especially in the liver, pancreas, spleen, kidneys and small intestine while they occurred only in traces in the blood, muscles and the brain. **II. The decomposition of nucleic acid through B. proteus.** *Ibid* 176–81.—*Proteus vulgaris*, grown on agar media, was transferred to a sterile medium contg. nucleic acid and allowed to incubate for 7 days. The following

compds. were proved to be present in the bacterial digest of yeast nucleic acid either by m. p., elementary analyses or both: succinic acid, hypoxanthine, xanthine and uracil; cytosine was not found. With thymus nucleic acid the same products were obtained and also thymine. No cytosine was isolated from the animal nucleic acid. **III. The partial hydrolysis of nucleic acid through plant nuclease.** *Ibid* 182–6.—On the digestion of yeast nucleic acid with an ext. of soy-bean powder, guanosine, adenosine and cytidine were isolated but no uridine. These mols. were proved to contain pentoses. On digestion with an ext. of spinach, adenosine was also proved to be present. When thymus nucleic acid was treated with soy-bean nuclease, guanine hexoside was formed. H. J. Deuel, Jr.

Denaturation of proteins by urea. W. Ramsden. *Nature* 126, 685(1930).—The rate of denaturation of approx. isoelectric egg albumin by urea has a neg. temp. coeff. H. J. Deuel, Jr.

The structure of the hemocyanins. I. The isolation of "hemocuprin," the copper component of hemocyanin. (Octopus vulgaris). Adolf Schmitz. *Z. physiol. Chem.* 194, 232–47(1931); cf. *C. A.* 24, 5771.—Hemocyanin, the blue pigment in the blood of molluscs and crustacea, may be coagulated without loss of respiratory function, and in this respect differs from hemoglobin. The moist coagulum retains the property of binding and again releasing O, as shown by alternate coloration and decolorization, but when completely dried it undergoes an alteration by which this property is destroyed. The Cu complex, however, is not split out unless the substance is treated with alkali. The linkage between metal component and protein is therefore more stable and of a different nature than that existing in hemoglobin. It is very resistant to acids, in fact more resistant than that of the metal itself, since the latter appears as ion before the entire complex is liberated. In the prepn. of the Cu component the finely powd. denatured hemocyanin is treated with *N* NaOH. The substance swells and soon takes on a reddish violet color. The color then gradually disappears but the soln. finally becomes dark and a green ppt. forms. The reaction is complete after 24 hrs. at 37°. After removal of the mother liquor which contains the protein component, the pptd. *hemocuprin*, as Na salt, is dissolved in hot H_2O or hot dil. EtOH to a dark wine-red soln. and repptd. by weak acids as a difficultly sol. green substance. Analysis gave the following values: C 45.04, H 6.99, N 12.58 and Cu 6.27%. P and S were absent. The substance has not yet been crystd.; hence the calcn. of an empirical formula was not attempted. The behavior of the substance toward solvents, the high H content which excludes an aromatic ring structure, and finally the spectroscopic behavior of the Na salt and the pyridine soln. of the acid show that a porphyrin structure is not present. Neither in structure nor in mode of linkage to protein does it resemble hematin. On the assumption that 1 mol. of hemocuprin contains 1 atom of Cu, the electrometric titration curve shows it to be a tetrabasic acid. It dissociates in 2 stages with dissocn. consts. of approx. 4×10^{-7} and 8×10^{-10}, resp. Titration of hemocuprin explains the color changes which occur also with hemocyanin itself. The alk. soln., *i. e.*, the quadrivalent ion of the dissocd. Na salt, is wine red. At p_H 8.5 a development of blue color begins and increases up to p_H 7.4, at which point the 2 weak acid groups have been neutralized, and the color is now pure blue. This represents the acid Na salt, *i. e.*, the bivalent dissocd. ion. Further titration changes the color to green until finally the green undissocd. acid seps. out The change of color to green, frequently observed with hemocyanin, has nothing to do with the formation of a hypothetical "methemocyanin"; it is a property of the undissocd. substance. Hemocuprin dissolves in concd. NH_4OH with a green color which changes to red when the soln. is dild. It contains no free NH_2, but when hydrolyzed by 8 hrs.' boiling with concd. HCl practically all of the N becomes NH_2. Similar treatment with concd. NaOH converts only 24% of the N to NH_2. This behavior is the reverse of that usually observed with polypeptides. The Cu is evidently not linked to NH_2 groups. A. W. Dox

Carbohydrate redoxase. Hans v. Euler and Ragnar Nilsson. *Z. physiol. Chem.* 194, 260–8(1931).—The hexosephosphate-dehydrogenase present in the seeds of jute (*Corchorus capsularis*) requires cozymase for its activity. If the cozymase of the seed ext. is removed by dialysis the enzyme action vanishes but can be restored by addn. of cozymase. The instability of enzyme action in the ext. is not due to lability of the enzyme but to destruction of the cozymase. Methylene blue reduction with fresh muscle and muscle ext. is activated by addn. of creatine. Washed muscle and dry prepns., on the other hand, are not activated by creatine. Both types of muscle prepn. are activated by creatinephosphoric acid. It is possible, however, that the activation may be due to a small impurity in the creatine and creatinephosphoric acid prepns. which exert a donor action. A. W. Dox

Use of radium emanation and method of its administration. J. STRASBURGER. *Klin. Wochschr.* **10**, 29–31(1931). H. EAGLE

Optical specificity of human liver esterase. P. RONA, R. AMMON, AND H. FISCHGOLD. *Klin. Wochschr.* **10**, 72(1931); cf. *C. A.* **25**, 976.—The results of Bamann and Laeverenz regarding the effect of strychnine upon the optical selectivity of human liver esterase in the hydrolysis of the racemic Et ester of mandelic acid have been confirmed. It has a similar effect upon the splitting of the *dl*-methyl ester, facilitating the splitting of the *l*-ester. The greater velocity of the *l*-hydrolysis is due to the fact that strychnine accelerates the splitting of the formed enzyme-*l*-ester combination by about 50%. H. EAGLE

The decomposition of the guanine nucleus by the enzymes of rabbit liver. GERHARD SCHMIDT. *Klin. Wochschr.* **10**, 165–7(1931).—A preliminary report. Details of the expts. and results will appear in *Z. physiol. Chem.* H. EAGLE

Physiological chemistry as an independent profession. D. ACKERMANN. *Klin. Wochschr.* **10**, 175–6(1931). H. EAGLE

Proteolytic enzymes of human white blood cells and blood serum. H. A. OBERKERS AND H. FISCHGOLD. *Klin. Wochschr.* **10**, 205–7(1931).—Human white cells obtained by centrifugation from a blood specimen hemolyzed by acetic and tartaric acids contain erepsin, trypsin and cathepsin. Blood serum contains only erepsin. H. EAGLE

Biological-chemical methods in the investigation of phylogenetic problems. ROBERT JARETZKY. *Arch. Pharm.* **269**, 50–62(1931).—An address. W. O. E.

Studies on pectin. V. The hydrolysis of pectin. ARTHUR G. NORMAN AND JOHN T. MARTIN. *Biochem. J.* **24**, 649–60(1930); cf. *C. A.* **25**, 1266.—The yields of Ca pectate, furaldehyde and CO_2 were estd. at intervals in the course of pectin hydrolysis carried out at 100°, with 0.5% and 0.2% alkali. The rupture of the pectin ring proceeds more rapidly than the destruction of the furaldehyde-yielding groups. A polyuronide deriv. of pectin was prepd. by alk. hydrolysis of pectin. BENJAMIN HARROW

Quantum problems in radiation biology. R. GLOCKER. *Naturwissenschaften* **19**, 20(1931).—From the recent results of Wyckoff (*C. A.* **24**, 5789; **25**, 129) on the influence of radiation on *B. coli*, conclusions can be drawn on the basis of G.'s theory as to the effect of electron impulses in a cell. The dying of the bacteria follows an exponential curve for waves between 0.5 and 4 A. U., the exponent consisting of the radiation dose factor and a probability factor. From the latter is derived the "apparent vol." V of the cell which is sensitive for radiation. W. found that V changes with λ; previous work of Lacassagne and Holweck on *B. pyocyaneus* with λ = 4–8 A. U. (*C. A.* **23**, 1928) gave a const. V. The mean path of an electron for λ = 0.56–2.3 A. U. is smaller than its range of action; hence the orbits of electrons originating outside V have to be included in the probability calcns. In accounting for this effect it is found that the true V is const. in all cases and that calcd. V values agree with the results of W. In the case of L. and H. the range of the electrons is far larger than their mean path and therefore does not affect V. For the calcn. the mean path inside the entire cell is to be used, not that inside the sensitive parts only ($^1/_{16}$ to $^1/_{100}$ of the total vol.). Apparently this indicates that several small sensitive spots are distributed all over the cell, a conclusion which is in agreement with the biol. conceptions of cells without nuclei. The change of V with λ and its const. value after correction for electron range is a direct proof for the quantum character of the influence of radiation on cells. B. J. C. VAN DER HOEVEN

The proteolytic action of papain and cathepsin. H. A. KREBS. *Naturwissenschaften* **19**, 133(1931).—Recently Waldschmidt-Leitz (*Ibid* **18**, 952(1930)) denied an increase in proteolytic activity of papain and cathepsin by removal of heavy metal from their solns. and attributed the increase obtained by K. (*C. A.* **24**, 3804) to the presence of HCN in the solns. freed from metal. In a further study it was found that at p_H 5 HCN up to concns. of 0.2 mole has no effect at all. The action of complex-forming substances (like HCN) depends on the nature of the metal impurity. If the metal is Zn as was proved formerly for this case, HCN has little effect; therefore removal of the metal is far more effective. If Au is present as inhibitor, HCN has considerable effect by changing the Au ions into complex ions (cf. also Grassmann in "Handbuch. d. Biochem." of Oppenheimer, p. 184(1930)). B. J. C. VAN DER HOEVEN

Specificity of animal proteases. XXII. Mode of action of peptidases. ARNOLD K. BALLS AND FRANZ KÖHLER. *Ber.* **64B**, 294–301(1931); cf. *C. A.* **25**, 1542.—In order to det. the mechanism of the reaction of aminopolypeptidase (I) of the intestine, the inhibitory effect of various substances on the action of I and of dipeptidase (II) was studied. The substances used were: benzoylglycine (III), benzoyldiglycine, benzoyltriglycine, bromoisocaproylglycine (IV), bromoisocaproyldiglycine (V), bromo-

isocaproyltriglycine (VI), *p*-nitrobenzoylglycine (VII), aceturic acid (VIII), phthalimide (IX), sarcosine (X), allantoin (XI), creatinine (XII), glycine anhydride (XIII), benzoylglycine with changing concn. of substrate, benzoylglycine with changing concn. of enzyme, benzoylsarcosine and some amino acids (glycocoll, α-alanine, *l*-leucine, *d*-glutaminic acid). From the results obtained certain conclusions may be drawn. That the inhibitory action of the NH group depends on its acid character is shown by the fact that III, IV, VII, VIII, IX and X inhibit the action of I; XI, XII and XIII do not. That only the peptide linkage adjacent to the acid residue has an inhibitory effect is shown by the fact that equiv. quantities of IV, V and VI show the same inhibition of the action. Bromoisocaproyltriglycyltyrosine shows an increased inhibitory action, since it has more than one NH group to react with the enzyme. The cleavage of natural peptides may perhaps be explained thus—that the COOH activates the NH group for reaction with the enzyme. This view is strengthened by the fact that X, which has no free NH_2 group but an NH group, inhibits the action of I. Yet for other reasons it seems that the activation of the NH group is caused by the enzyme, *i. e.*, that the union of the enzyme with the NH_2 group of the peptides first renders the NH group capable of functioning as the second point of attachment. The results support the theory that the NH group functions as a point of attachment for all peptidases. This is the first common principle found for the action of peptidases. LOUISE KELLEY

A new proteolytic action of extracts of intestinal mucous membrane. ARNOLD K. BALLS AND FRANZ KÖHLER. *Ber.* **64B**, 383-7(1931); cf preceding abstract and *C. A.* **25**, 1542.—Although dipeptidase and aminopolypeptidase from intestinal mucous membrane attack the NH_2 and NH groups of peptides, glycerol exts. of the membrane show a hydrolytic action of peptide-like substances which contain no NH_2 or COOH groups, *e. g.*, chloroacetyl-*o*-nitraniline. The enzyme action described here belongs to a new type of peptidases which apparently react only with the NH group. The enzyme seems either to be present in very small quantities or to lose its activity easily as a result of inhibitory substances, for in the expts. the increase in acidity was very slight. Expts. with chloroacetyl-*p*-nitroaniline and benzoyltriglycine showed the optimum p_H for cleavage to be about 8. LOUISE KELLEY

The crystallization, denaturation and flocculation of proteins with special reference to albumin and hemoglobin, together with an appendix on the physicochemical behavior of glycine. W. C. M. LEWIS. *Chem. Reviews* **8**, 81–165(1931).—Certain aspects of the behavior of denaturable proteins in respect to crystn., denaturation and flocculation are reviewed. A no. of closely related problems are also considered, among them the physicochem. behavior of glycine in soln. LOUISE KELLEY

Action of sulfhydryl, iron and cyanide compounds on the oxygen consumption of living cells. SANFORD M. ROSENTHAL. *U. S. Pub. Health Repts.* **46**, 521–39(1931).—Glutathione, either in the oxidized or reduced form, when added to various tissues or to yeast cells, does not accelerate the rate of O consumption. Under the conditions of these expts., rat liver, brain, testicle, Jensen sarcoma and chicken erythrocytes are able to keep SH glutathione in the reduced state. The addn. of considerable quantities of cysteine and Fe to these tissues does not overcome this property. Cysteine is also kept reduced by these tissues, even in the presence of added Fe. Rat kidney permits the slow oxidation of glutathione and cysteine. Blood serum causes a marked acceleration in the rate of oxidation of glutathione. Hemin, Na Fe tartrate or $FeSO_4.(NH_4)_2SO_4\ 6H_2O$ causes no acceleration of the O consumption of rat tissues or yeast cells. Methemoglobin, Na Fe tartrate and $FeSO_4\ (NH_4)_2SO_4\ 6H_2O$ can prevent part of the inhibition of O uptake caused by NaCN. Oxyhemoglobin is less effective, while hemin shows no effect. Neither oxidized nor reduced glutathione influences the inhibition of respiration by cyanide. However, a slight antagonism can be demonstrated if S-S glutathione and cyanide are allowed to react for a considerable time before they are added to the tissue. KCN and α-amino-β-sulfopropionic acid do no inhibit the O consumption of rat testes. KCNS causes a slight increase in the rate of O consumption of rat testes. The significance of these results with respect to the mechanism of the action of cyanide upon living cells is discussed. J. A. KENNEDY

Kinetics of esterase activity in comparison with acid catalysis. ERNST A. SYM. *Biochem. Z.* **230**, 19–50(1931).—To avoid inactivation of esterase by the substrate and to provide a suitable solvent for the various org. acids, alcs. and esters, an acetone medium was found most favorable. In studying the inactivation of the esterase in the presence of 0.2 mol AcOH per l. it was found that this becomes less as the mol. wt of the alc. increases (up to butyl alc.) and this is also true for the homologous fatty acids of the aliphatic series. The inactivation of the esterase by H_2O in an acetone medium becomes considerable at a concn. of 6–8 mols. per l. Comparative expts.

with esterase and with HCl catalysis at different concns. of butyl alc. showed that the reaction velocity const. is subject to large variations. Water activates esterase and inhibits HCl catalysis. The esterase activity increases with a rise in the butyric acid concn., very rapidly up to a concn. of 0.6 mol. per l.; then it remains const. or even diminishes. The velocity of the esterification reaction of different alcs. of the homologous series, with esterase or HCl, or under the influence of heat is practically the same. However, the influence of homologous acids on the kinetics of esterification is entirely different for esterase than for the HCl catalysis or for the thermal reaction. The hypothesis is developed of the ester formation by a process of contact catalysis.

S. MORGULIS

Characterization of proteins through the determination of their affinities. G. ETTISCH, H. SACHSSE AND W. BECK. *Biochem. Z.* 230, 68–92(1931).—The affinity of the proteins for Cu is measured by the e. m. f. of the compd., and this is offered as a means of identifying the different proteins. The reaction between alk. protein solns. and $CuSO_4$ (biuret reaction) has been studied quantitatively, the e. m. f. being detd. in relation to the protein, Cu, alk. concns. and temp. in the following chain: Cu|protein + NaOH|KCl|$CuSO_4$|Cu. The influence of the alkali at the end of 24 hrs. reaches a definite point which could be detd. not only by studying the e. m. f. but also changes in depolarization, viscosity and light absorption. Electrochem. differences become apparent especially in high protein concns., when the e. m. f. with rising NaOH concn. is found to increase much more with albumin than with globulin. On the contrary, with increasing Cu concn. the e. m. f. of the albumin diminishes more rapidly than that of the globulin. These facts are interpreted as showing that in albumin the Cu-binding groups have a greater affinity for the Cu than in globulin, but that their no. is smaller in albumin than in globulin. Certain theoretical and methodical points are discussed in connection with this study. S. MORGULIS

Depolarization and light absorption of alkaline protein solutions. G. ETTISCH, H. SACHSSE AND B. LANGE. *Biochem. Z.* 230, 93–114(1931).—The depolarization of alk. protein solns. varies with time and with the alkali concn. These alterations are due to the swelling as well as breaking up of the protein particles, which only occur in the presence of sufficiently large alkali concns. Globulin is more easily broken up than albumin. S. MORGULIS

Viscosity of alkaline protein solutions. G. ETTISCH AND H. SACHSSE. *Biochem. Z.* 230, 115–28(1931).—The flow elasticity of albumin or globulin solns. shows no measurable alteration within a wide reaction range, but there is an indication of a form elasticity as soon as a few cc. of $CuSO_4$ soln. is added to a highly concd. alk. soln. of albumin or globulin. In fact under some conditions the solns. may become solidified on the addn. of the $CuSO_4$. The viscosity increases with increased alkali addn. after a certain concn. (satn. concn.) has been exceeded which causes far-reaching alterations in the protein mol. The ability to split up is greater in globulin than in albumin, and this is considered to be responsible for the fact that the globulin is more hydrophile. S. MORGULIS

The chemical independence of the serum proteins. G. ETTISCH AND H. SACHSSE. *Biochem. Z.* 230, 129–35(1931).—The euglobulin fraction obtained by 1/3 satn. with $(NH_4)_2SO_4$ corresponds to the globulin fraction by electrodialysis. The paraglobulin obtained by half satn. with $(NH_4)_2SO_4$ is an independent chem. substance, which occupies a definite position between the globulin and albumin. The transformation of one into another is not very probable. S. MORGULIS

Influence of lecithin on the stability of the serum proteins. ISTVÁN WENT AND FERENC FARAGÓ. *Biochem. Z.* 230, 238–44(1931).—On mixing an aq. lecithin emulsion with serum a definite reciprocal relationship is manifested in the alteration in the amts. of euglobulin and pseudoglobulin I on the one hand, and between pseudoglobulin II and albumin, on the other. Conclusion: Euglobulin is a colloidal complex of pseudoglobulin and lecithin, and the same may also be true for the pseudoglobulin II (pptd. by 21.5% Na_2SO_4) and albumin. Between the 2 main types of serum protein there seem to be less definable dispersoids whose precipitability by neutral salts varies greatly according to the amt. of lecithin. S. MORGULIS

The specificity of phosphatase. KURT P. JACOBSOHN AND JOAO TAPADINHAS. *Biochem. Z.* 230, 304–11(1931).—Mono- and di-menthyl phosphate and di-menthyl pyrophosphate esters could not be hydrolyzed by phosphatase. S. MORGULIS

The destruction of cystine and of cysteine through illumination. FRITZ LIEBEN AND ERICH MOLNAR. *Biochem. Z.* 230, 347–52(1931).—Both cystine and cysteine

undergo decompn. under the influence of light from the quartz-Hg lamp or diffuse daylight, but this proceeds at a much slower rate than with aromatic amino acids. In diffuse daylight the destruction of cystine goes on only in an alk. medium, while that of cysteine must be followed in an acid medium since it oxidizes spontaneously in an alk. medium. Hematoporphyrin must be used as a sensitizer with the cysteine. Under the influence of the illumination with the quartz-Hg lamp no sensitizer is necessary, but the rate of the reaction without it is markedly slower. The products of radiation of cystine when added to tryptophan or to tyrosine diminish their color reactions. The reduction of methylene blue in diffuse daylight by cysteine as compared to that in the dark shows that with an increase in the acidity the difference in time required for the fading of the color becomes constantly greater while at the same time the rate of fading sharply decreases. S. MORGULIS

Refractometric studies on serum protein. III. The specific refraction for the total protein and for the non-protein substances of horse serum. D. VON DESEÖ. *Biochem. Z.* **230**, 373–82(1931); cf. *C. A.* **24**, 1874.—The refractive index and sp. gr. were detd. at 17.5°, also the total protein gravimetrically, in 30 horse serums, both normal and immune. A study of the data leads to the following formulation: The refractive index of the serum, R. I. − 1.33320 = 0.00209 + 0.00187 × protein content, with an av. error of ±0.00002. Or, specific gravity of the serum, S. G. − 1.0 = 0.00752 + 0.00268 × protein content, with an av. error of ±0.00005. The R. I. and S. G. of the non-protein materials of the serum are 0.00209 and 0.00268, resp. The increase in the specific refraction of serum protein is 0.00187 and that of the specific wt. 0.00268 per unit of protein. **IV. Increase in the specific refraction of the protein fractions in horse serum.** *Ibid* 383–94.—Three groups of serum proteins were studied from the point of view of their *ns*. The first group was represented by the proteins pptd. by satn. with a definite amt. of $(NH_4)_2SO_4$ and the second by those remaining in soln. in the serum. The former comprised all the globulins with an av. *n* of 0.00195 ± 0.00001 and a corresponding sp. gr. of 0.00298 ± 0.00005. Corrected on the basis of sp. gr. data, the *n* should be 0.00187, which is the same as that for the albumin. The third group was represented by mixts. of both albumins and globulins. Here the *n* was 0.00185 ± 0.00002 and the sp. gr. 0.00272 ± 0.00005. It has been further substantiated that for 1% serum protein the variations in *n* and sp. gr. are, resp.: 0.00187 ± 0.00001 and 0.00268 ± 0.00005. S. MORGULIS

Hydrotropic solution of calcium, with reference to the solution of calcium in blood serum. A. VON KUTHY AND H. BANGA. *Biochem. Z.* **230**, 458–65(1931).—Ca dissolved hydrotropically in a Na salicylate soln. behaves like a serum Ca in that part of it is ionized, is negatively charged and part is in a non-diffusible condition. It is therefore suggested that serum Ca is hydrotropically dissolved. S. MORGULIS

Comment on the paper of Schreiber and Friedrich: "Demonstration and intensity of mitogenetic radiations." A. GURWITSCH. *Biochem. Z.* **230**, 505(1931).—Discussing the neg. findings of these authors (*C. A.* **25**, 529) G. points out that agar yeast cultures do not radiate in the dark but can still be used as detectors. S. MORGULIS

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Determination of p_H of [biological] media. M. LEMOIGNE AND R. CHAMINADE. *Compt. rend. soc. biol.* **102**, 922-3(1929).—When the colorimetric method is inapplicable and the electrometric method troublesome, the medium may be brought into electrometric equil. with a phosphate mixt. of colorimetrically detd. p_H. B. C. A.

Detection of necrosis of pancreatic tissue by determination of urinary diastase. J. WOHLGEMUTH. *Klin. Wochschr.* **8**, 1253-4(1929).—W.'s method for the detn. of urinary diastase in presence of a phosphate mixt. of p_H 7.2 is described. B. C. A

Microdetermination of proteins. R. WINTERNITZ AND Z. STARY. *Mikrochemie* [N. S.], **2**, 252-6(1930).—A quantity of the soln. contg. not more than 1.5 mg. of protein is centrifuged for 15 min. with 2 cc. of 20% trichloroacetic acid, the liquid decanted, and the pptd. washed with 4% trichloroacetic acid, and heated with a mixt. of H_2SO_4 and H_3PO_4 to destroy org. matter. The mixt. is dild. to 17.5 cc., 7.5 cc. of Nessler soln. is added, and the color developed is compared with a series of standards. B. C. A.

A critique of present methods for the study of gastric acidity. MILTON J. MATZNER AND IRVING GRAY. *Arch. Internal Med.* **47**, 58-63(1931).—The methods of gastric analysis are discussed. Histamine should be used as a gastric stimulant if the routine test gives no free HCl. A definite alk. tide was found in 50% of the cases showing free HCl after injection of histamine. J. B. BROWN

The detection and estimation of lactose in urine. C. P. STEWART AND R. M. GRAY. *Edinburgh Med. J.* **38**, 109-12(1931).—The total sugar (A) in the urine is detd. by Cole's method and calcd. as glucose. The total sugar (B) in urine hydrolyzed with HCl is calcd. in the same way. The amt. of glucose (y) and the amt. of lactose (x) can be calcd. from the equations: $y + x/2 = A$, $y + x = B$. The method is suitable for the examn. of urine during pregnancy and lactation. R. B.

The technic of tissue culture in hanging drops. ALEXIS CARREL. *Compt. rend. soc. biol.* **102**, 742-4(1929).—The p_H of tissue cultures is regulated by flooding a culture chamber with expiratory breaths until an indicator drop (phenol red in a drop of medium) shows that the desired p_H has been reached. The chamber is formed by a metal ring, 5 cm. in internal diam. and 1 cm. high; at each end of the ring is a ledge, 0.25 cm. deep. A mica sheet is affixed to each end by paraffin. At one end of the ring there are 2 openings in opposite walls; provision is made for the insertion of a metal cannula, to which rubber tubing may be attached, to flood the chamber with expired air. Four tissue cultures may be observed simultaneously. B. C. BRUNSTETTER

A diazo method for detecting bilirubin in urine. GEORGE HUNTER. *Can. Med. Assoc. J.* **23**, 823-4(1930).—The possibilities of detecting bilirubin in icteric urine have been reinvestigated, and a satisfactory qual. test, which might form the basis of a quant. method, is as follows: To 5 cc. of urine in a 15-cc. centrifuge tube add 2 cc. of 10% $BaCl_2$, mix and centrifuge. Pour off the supernatant fluid, wash the ppt. with a few cc. water, centrifuge again and pour off the liquid. Add 0.5 cc diazo reagent, stir the ppt. with a glass rod, and add 2 cc. of 96% alc., and, as buffer, 0.3 cc. of 6% $Na_2HPO_4.12\ H_2O$. If bilirubin is present the same color results as with the diazo reagent and icteric serum. If the urine is alk. add AcOH initially till weakly acid. If it is highly pigmented, after the Ba ppt. is obtained stir with 2 cc. of 96% alc. to which has been added 1 drop of 10% H_3PO_4, centrifuge and transfer the supernatant fluid to a second tube along with 4 cc. water. Add 2 drops 10% $(NH_4)_2SO_4$ and 2 cc. $BaCl_2$, repptg. the bilirubin, and proceed as above. A. T. CAMERON

The colorimetric determination of nonprotein residual nitrogen in blood. G. A BROSSA. *Atti accad. sci. Torino* (Classe di sci. fis., mat., e nat.) **65**, 272-4(1930) Methods of analysis which may be applied readily without very elaborate app. or technic are being developed in biochemistry as an aid in diagnosis (*i. e.*, tests for sugar, uric acid, etc.). A method is described for detg. *nonprotein N* without the necessity of any distn. De-albuminize 1.2 cc. of blood serum in 8.8 cc. distd. water by adding 4 cc. of 10% sulfosalicylic acid soln. After 30-60 min. filter the soln., and, after adding 1 cc. of H_2SO_4 and a crystal of K_2SO_4, evap. it to dryness. Redissolve the residue with water to exactly 12 cc. Use 2 cc. to det. the amt. of 30% NaOH necessary to make the soln. alk. to litmus. Then add the calcd. amt. to the 10 cc. left and add 2 cc. 10% PhOH soln. and 0.6 cc. of freshly prepd. NaOCl soln. Heat this mixt. as well as a standard soln. for comparison in boiling water for 10 min., cool and compare the colors with the help of a colorimeter. A. W. CONTIERI

The calculation of the color index of blood. FRANZISKA STENGEL. *Wiener*

klin. Wochschr. **44**, 194–7(1931).—An alignment chart shows color index, in terms of *erythrocyte count* and quantity of *hemoglobin*. The latter is detd. by the Hellige or the Sahli method. D. B. DILL

Determination of small quantities of zinc in the presence of lead salts. M. W. STAS. *Pharm. Weekblad* **68**, 93–7(1931).—Zn may be detd. by pptn. with *o*-hydroxyquinoline in solns. contg. 1% AcOH and 4% NaOAc in the presence of Pb, provided the concn. of Pb does not exceed 100 mg. per 50 cc. The pptd. Zn salt of *o*-hydroxyquinoline is detd. volumetrically by bromination with $KBrO_3$ + KBr and titrating the excess Br with $Na_2S_2O_3$ as recommended by Berg (*C. A.* **21**, 2630). A. W. DOX

Titrating organic acids in the urine. WILHELM WERTZ. *Klin. Wochschr.* **9**, 1632(1930).—Occasionally the tint of the urine precludes or makes difficult the use of tropeolin OO as indicator in the titration of urine org. acids by the Van Slyke-Palmer technic. In such cases H. recommends the use of β-dinitrophenol. H. EAGLE

New reactions of bilirubin in blood serum. GABRIEL MONASTERIO. *Klin. Wochschr.* **9**, 1772–3(1930).—If one adds 1 drop of H_2O_2 and 1 drop of glacial acetic acid to 5–6 drops of serum, a green color develops in the presence of bilirubin, which is intensified by heat. By heating serum with the diazo reagent of van den Bergh, sera which would otherwise give an indirect reaction give a direct reaction. Alc. is a similar "catalyst." H. EAGLE

Microestimation of the nitrogenous constituents of urine. LUDWIG PINCUSSEN. *Klin. Wochschr.* **9**, 1966–7(1930).—A reply to the criticism of Jacoby (*C. A.* **24**, 5775). Pincussen believes 15 min. distn. quite adequate. H. EAGLE

Estimation of blood volume in congenital heart defect. KARL HITZENBERGER AND FRITZ TUCHFELD. *Klin. Wochschr.* **9**, 2159–60(1930). H. EAGLE

Hormonal reaction for pregnancy with the urine of humans and animals. BERNHARD ZONDEK. *Klin. Wochschr.* **9**, 2285–9(1930).—The hypophyseal hormone has been demonstrated in the urine of pregnant women, apes and horses, but could not be found in cows, pigs, elephants or Rodentia. The urine of pregnant mares contains about 10 times as much folliculin per unit vol. as that of pregnant women, but, unlike the latter, is in a form not sol. in org. solvents. From such urine it is possible to prep. large quantities of cryst. hormone, contg. 8000 units per g. The folliculin content of blood is only $^1/_{100}$ that of the urine. In marked contrast, the blood of pregnant horses contains large quantities of hypophyseal anterior lobe hormone, as shown by the ovarian hyperplasia and the formation of corpora lutea induced by its injection into infantile rats; but the urine contains only minimal quantities. The longer the pregnancy, the less of the hypophyseal hormone circulates in the blood. Z. distinguishes 2 types of the hypophyseal hormone: (1) HVH-A, which causes ripening of follicles, and (2) HVH-B, which causes luteinization. No explanation is offered for the massive excretion of folliculin by the pregnant horse, and the retention of the HVH, particularly HVH-B. It is important to note that in the diagnosis of pregnancy in women, the essential criterion is the presence of HVH-B in the urine, which induces luteinization and the formation of blood spots on the ovary of the test animal; both folliculin and HVH-A may appear in the urine during other conditions, such as at the menopause, in amenorhea, etc. In the horse, however, the best criterion is the induction of rut in the infantile rat, as shown by the appearance of cells in the vaginal smear. This is a test for the enormous increase in the urine folliculin and is more accurate if the urine to be tested is first acidified, filtered and extd. with ether to remove an uncharacterized inhibiting factor. In 9 virginal mares, this test was uniformly neg.; in 54 pregnant, it was positive in 53; and in 17 mares which had been mounted but had not become pregnant, the test was pos. only once: a total error of only $2^1/_2$%. H. EAGLE

A new method for the estimation of glucuronic acid in the urine. JOACHIM SAUER. *Klin. Wochschr.* **9**, 2350–1(1930).—The ether ext. of the acidified urine is evapd. to dryness, heated with 12% HCl, and the glucuronic acid estd. by the usual Lefèvre app. The av. daily excretion is 0.22–0.29 g. H. EAGLE

A method for the determination of organic iodine (uroselectan) in the urine. K. HILLGRUBER. *Klin. Wochschr.* **9**, 2353–4(1930).—The urine is oxidized with hot H_2SO_4 and H_2O_2; the I, now free from its org. radical, is then oxidized with Cl water in alk. soln. to HIO_3, and this is titrated in acid reaction with KI and $Na_2S_2O_3$. H. EAGLE

The peroxidase reaction. XXVIII. An exceedingly sensitive peroxidase reagent for human milk. TAYURU ARAKAWA. *Tôhoku J. Exptl. Med.* **16**, 83–9(1930).—Reagent *A* consists of guaiac resin 0.3–1 g., As_2O_3 0.02 g., glacial AcOH 0.6 g., AcONa 1.30 g. and 99% EtOH to make 100 cc. Reagent *C* consists of pharmacopeial tincture with 0.1% peroxide (cf. *C. A.* **25**, 1330) 1, and guaiacol 2 parts, and acetone to make

100 cc. A mixt. of *A* and *C* is used for qual. tests. For quant. tests reagent *B* (benzidine 1 g., AcONa 1.36 g., and 99% alc. to 100 cc.) and reagent *D* (described in part XXX, below) are used. Despite the fact that the qual. test is 64 times as sensitive as those currently used, it fails to react with blood and can, therefore, be used for testing pus, spinal fluid and milk which are contaminated with blood. **XXIX. Determination of human milk peroxidase. 1. Dilution method.** *Ibid* 90–96.—A diln. method in which are used reagents *A* and *C* (part XXVIII, above) is described. **XXX. Determination of human milk peroxidase. 2. Colorimetric method.** *Ibid* 97–106.—The reagents used are (1) reagent *B* (part XXVIII, above), (2) reagent *D* (a 3% soln. of H_2O_2 0.1, and guaiacol 2 parts and 99% EtOH to make 100 cc.), (3) Walpole's acetate mixt. at p_H 3.6 dild. 1:10 with 0.9% NaCl, (4) $CHCl_3$, (5) 0.1 *M* AcONa in 96% alc., (6) a standard soln. consisting of a $CHCl_3$ ext. of $Cu(OAc)_2$. Equal vols. of (1) and (2) are added to one vol. of milk (whole, or dild. with (3)), and the mixt. is extd. with $CHCl_3$. The ext. is made up to 5 cc. with 96% alc., and compared colorimetrically with the standard. **XXXI. An approximate estimation of milk peroxidase.** *Ibid* 107–11.—To 1 cc. of milk are added 3 cc. of *M* 15 phosphate buffer at p_H 7.8, 1 cc. of reagent *A* (above) and 1 cc. of reagent *C* (above). In a milk contg. large quantities of peroxidase, a deep-blue color develops immediately. **XXXV. A rapid micro method for peroxide by the use of milk peroxidase; preservation of milk peroxidase.** *Ibid* 232–5.—To 0.5 cc. of reagent *A* are added decreasing quantities of the substance to be tested, and 0.25 cc. of standard peroxidase; the color which develops is compared with that formed by a known peroxide soln. (3% H_2O_2 dild. 1:100). Milk peroxidase may be preserved indefinitely by the following technic: 100 cc. of milk is shaken with 10 cc. $CHCl_3$, 10 cc. 95% EtOH and 1 cc. guaiacol; 0.5 cc. glacial AcOH is added and the mixt. filtered 24 hrs. later. The filtrate keeps indefinitely. H. EAGLE

Sulfosalicylic acid as protein reagent. HUGO KÜHL. *Süddeutsche Apoth.-Ztg.* **70**, 665–6(1930).—Sulfosalicylic acid is a useful reagent in physiol. chemistry, notably in the detection of albumin in urine. In the present study expts. have been carried out to characterize the various ppts. obtained by treating certain sol. proteins with 1 cc. of the reagent. The protein solns. examd. contained 0.5% albumin. Among the proteins examd. were albumin Merck and Sanguin, natural albumin of duck eggs, meat albumin, plant albumin, gelatin, peptone, keratin, etc. On addn. of the reagent the soln. is heated to boiling, and observations are made on the time required to produce a ppt. (if any), the character of this ppt., being noted. The value of sulfosalicylic acid as a precipitant lies in the fact that the nature of the ppt. often enables one to det. what protein is involved. W. O. E.

Chemical detection of blood according to Segeloff. PAUL SCHUGT. *Pharm. Presse, Wiss.-prakt. Heft* **1930**, 166–7.—This test, applicable to the detection of blood in the urine or feces, in conjunction with spectroscopic and microscopic tests, involves the following procedure: While the urine may be tested directly, the feces require a preliminary treatment, as trituration of a 30-g. sample in a mortar with a like amt. of 0.5% AcOH, followed by filtration through a wet (if necessary, double) filter. To 5 cc. 5% pyramidone soln. in abs. EtOH, add 8 drops 3% H_2O_2 soln., 8 drops 50% AcOH and 10 drops of the urine or feces filtrate. The presence of the minutest traces of blood in either sample is shown by a violet to light-blue coloration. This test is about 10 times more delicate than that of Almen and about 3 times more sensitive than the Adler test. An improvement on the Segeloff procedure consists in treating 1 cc. of the sample in a test tube with 8 drops AcOH and 8 drops H_2O_2, and then, with the tube in an oblique position, adding, drop by drop, the pyramidone reagent. The first 10 or 15 drops mix with the soln. mixt., whereas further addn. of the reagent develops a layer superimposed on the lower, the zone of contact showing a light-blue to amethyst-violet coloration. W. O. EMERY

Selective staining of basophilic granules. EUGENE BUJARD. *Bull. histol. appl.* **7**, 264–9; *Stain Tech.* **6**, 31(1931).—The technic is described. C. R. FELLERS

Histochemical detection of hemoglobin. L. LISON. *Rev. hyg. méd. prév.* **52**, 894–6; *Compt. rend. soc. biol.* **103**, 36–8(1930).—Hemoglobin in blood is transformed to hematin by treatment with the following mixt.: Pb acetate 2–5 g., CH_2O 10 cc. and distd. water 100 g. Peroxidases in the hemoglobin are uninjured by the treatment and give a characteristic benzidine-H_2O_2 reaction (blue color). The reaction is sp. for hemoglobin. C. R. FELLERS

Colorimetric determination of phenols in feces. DEBERGH AND R. GOIFFON. *Rev. hyg. méd. prév.* **53**, 78–80(1931).—Dil. 10 g. of feces to 100 cc. and treat 5 cc. of this soln. with 5 cc. of 10% Na tungstate and 5 cc. of 0.66 *N* soln. of HCl. In a few min. stir the soln. and filter. To 6 cc. of the filtrate, corresponding to 2 cc. of the 1:10 diln.

of feces, add 5 cc. of an aq. soln. of 2.5% $ZnCl_2$ and 5 cc. of 20% Na_2CO_3 soln. Agitate the mixt. and filter. Place 8 cc. of the clear filtrate in a 30-cc. cylinder together with the phenol reagent and make up to 25 cc. with distd. water. Finally add 5 cc. of a 20% soln. of Na_2CO_3, shake the mixt. and set aside for observation at the end of 1 hr. The development of a blue color indicates the presence of phenols. The amt. may be estd. by colorimetric comparison with a standard made up by adding 0.091 g. of resorcinol per l., and treating 1 cc. of this soln. by the method just described. This amt. of resorcinol gives the same intensity of color as 0.1 g. of phenol per l. The method is considerably more accurate than the original Folin and Denis technic. C. R. F.

New rapid method for tissue diagnosis. CHARLES F. GESCHICKTER, EDWARD P. WALKER, A. M. HJORT AND CARL H. MOULTON. *Stain Tech.* **6**, 3–12(1931).—A new staining procedure applicable to both fresh and CH_2O-fixed frozen sections is described. A pre-staining bath consisting of KH_2PO_4 6.75 g., *N* NaOH 30 cc., distd. water 570 cc., glycerol 200 cc. and 95% EtOH 200 cc. is used to collect the sections as they come from the microtome. The sections are then passed into the following staining soln. for 20–30 sec.: thionine eosinate 0.75 g., Ba eosinate 0.25 g. and azure A 0.25 g. dissolved in 100 cc. of a mixt. of 4 parts of $(CH_2OH)_2$ and 1 part of EtOH 95% plus 0.2% glacial AcOH. The stain is washed off in 2 successive changes of 95% EtOH contg. 200 cc. of glycerol to each 80 cc. of EtOH. The tissue is left in the first bath about 10 sec. and in the second bath 3 sec. Sections are dehydrated by floating for 10–15 sec. in a soln. of diethylene glycol monobutyl ether and cleared in butyl phthalate by floating in this soln. for 20 sec. The section is finally floated on a glass slide, blotted dry with photographic lintless blotting paper and covered with an inverted cover slip upon which 1–2 drops of dammar gum has been placed. C. R. F.

Dissection, staining and mounting of styles in the study of pollen-tube distribution. JOHN BUCHHOLZ. *Stain Tech.* **6**, 13–24(1931).—Details of the method are given. C. R. FELLERS

Method of staining pollen tubes within the pistil. CLYDE CHANDLER. *Stain Tech.* **6**, 25–6(1931).—A very satisfactory killing soln. consists of 6–7 cc. of com. CH_2O in 70% EtOH. The method of dissection and staining with acetocarmine is outlined. C. R. FELLERS

Lacmoid-Martius—yellow for staining pollen tubes in the style. B. R. NEBEL. *Stain Tech.* **6**, 27–9(1931).—The staining technic is described. The callose stain permits of interpreting the physiol. condition of the tube more readily than a stain of the plasmatic content alone. The method is particularly valuable with fleshy styles such as are found in pomaceous plants, cherries, plums and grapes. C. R. FELLERS

Method for detecting mineral particles in tissues, particularly in lung tissue. A. POLICARD. *Bull. hist. appl. physiol. et path.* **7**, 129–31(1930); *Physiol. Abstracts* **15**, 203; cf. *C. A.* **24**, 3579.—A method is described for detecting such particles in lung tissue, but it is applicable to other investigations. Concd. $HClO_4$ is used to dissolve or render transparent the org. particles. The paraffin section is treated with xylene, then alc., and dried; it is covered with a drop of strong $HClO_4$ and heated on a boiling water bath until it becomes transparent; it is immediately cooled and examd. The method is of value in studying the mineral deposits found in the lungs in certain miners' diseases. G. G.

Ultrafiltration in vivo. L. BRULL. *Compt. rend. soc. biol.* **99**, 1605–7(1928); *Physiol. Abstracts* **14**, 482.—The principle of the ultrafilter of Giemsa is adapted to an app. to receive the blood from the carotid of a dog after the injection of heparin to prevent coagulation. The ultrafiltrate from the plasma is obtained in sufficient quantity to permit physicochem. study. G. G.

Action of ox bile in filtration. D. COMPRESEO AND A. DAMBOVICEANU. *Compt. rend. soc. biol.* **103**, 182–4(1930); *Physiol. Abstracts* **15**, 80.—Ox bile was used to facilitate the passage of substances in emulsion through filters, Chamberland bougies and collodion sacs. Victoria blue and Congo red do not pass in ordinary conditions, but the latter in 1 per 2,000 soln. passes through the bougie to a slight extent. Addn. of bile (1 *in* 10 to 1 *in* 100) facilitates the passage of both. *Bacillus pyocyaneus* also passes through the bougie after the use of bile. G. G.

Colorimetric estimation of phenols in feces. MME. TONCKHEERE-DEBERGH AND R. GOIFFON. *Compt. rend. soc. biol.* **103**, 485–7(1930); *Physiol. Abstracts* **15**, 207.—Errors occur in the filtration of tungsto-molybdic ppts. in the method of Folin and Denis. These are obviated in the method employed by the authors for detg. phenols in feces. In this process the tungstic filtrate is treated with $ZnCl_2$ and Na_2CO_3. The $ZnCO_3$ retains the S, which is capable of acting on the colorimetric agent, and the resulting color is easily compared with the standard resorcinol color. G. G.

Importance of protein precipitation in amino acid determination in blood. P. M. Re and D. Potick. *Rev. soc. argentina biol.* 5, 725–44(1929).—Folin's method gives values below the real ones, and the error increases with the concn. in amino acids. The tungstate-H_2SO_4 mixt. used to ppt. the proteins diminishes the values obtained up to 50%. Trichloroacetic acid gives a much smaller error. Phosphotungstic acid gives intermediate values. G. G.

Methods for the study of the physiology and pharmacology of the artificially perfused mammalian intestine. H. F. Roese. *Arch. ges. Physiol.* (*Pflügers*) **226**, 171–83(1930).—Various methods are described for perfusing mammalian intestine. Arthur Grollman

Microchemical examination of very small quantities of skin for phenolic substances. Hans Schmalfuss and Helene Barthmeyer. *Mikrochemie* [N. S.], 2, 245–52(1930).—*Melanogen* is a provisional name given to any substance which turns an enzyme strip of the flour beetle, *Tenebrio molitor* L., brown, gray or black. In studies concerning inheritance and development, it was desirable to test for the distribution of melanogens, *e. g.*, *o*-dihydroxybenzenes, in organisms, particularly in the colored skins of insects. By means of simple methods, most of them already known, it was found possible to do this with very small quantities of material. To ext. the color, $1–6 \times 10^{-3}$ cm. of material was pulverized, a suspension made with 0.008–0.25 cc. of water, the suspension was transferred to a small test tube and heated for 2 min. in boiling water to destroy injurious enzymes. The soln. was then filtered and tested with enzyme test strips. Tests were also made with $FeCl_3$–Na_2CO_3 for dihydroxybenzenes and for phenols by Gibb's reagent and with Millon's reagent. The work is described in detail and will be interesting to those who desire to make similar tests. W. T. H.

A modification of MacCallum's hematoxylin method for iron. R. R. Dieterle. *Arch. Path.* 10, 740–1(1930).—In the original method of MacCallum for the staining of unmasked Fe a freshly prepd. 0.5% aq. soln. of hematoxylin was used. The modification consists in the addn. of 1 cc. neutral CH_2O soln. to 100 cc. of the hematoxylin soln. The CH_2O acts as a reducing agent and prevents the natural oxidation of the hematoxylin soln. Such a CH_2O-hematoxylin soln. has been used for 3 months without losing its ability to combine with the Fe. Harriet F. Holmes

The state of acidity of the stomach contents and its clinical estimation. F. Erben. *Wiener Arch. inn. Med.* 20, 353–74(1930); cf. *C. A.* 24, 3527.—By the use of the phloroglucinol-vanillin test of Günzberg, the free HCl can be detd. in the stomach contents. This is no test for H-ion content as with the same p_H value, solns. of HCl, tartaric acid and citric acid react positively and solns. of normal fatty acids and lactic acids negatively. The HCl bound to proteins cannot be detd. by any direct titration method. Its estn. follows the detn. of free HCl and of the total HCl after the methods of Sjoqvist or Lüttke-Martius. By use of these methods it is possible to distinguish in the stomach contents between HCl as the normal acid of the stomach and the accidental acids of the food or pathologic org. acids. The detn. of the actual acidity directly or indirectly (titration of the indicator according to Sahli) is not superfluous or to be ignored but is supplemented. As the taste of the acids is not due to the H-ion concns. alone, but to the equiv. concn., the equiv. concn. must be considered as well as the actual acidity. In order that results may be compared in writing on the acidity of the stomach contents the nature of the test meal should be given and the methods used such as: total acidity (α-naphthaolphthalein) or total acidity (phenolphthalein), free HCl (dimethyl yellow), actual acidity (Sahli). Harriet F. Holmes

A new simple method for preserving microscopical stained films. M. van Riemsdyk. *Nederland. Tijdschr. Hyg., Microbiol. en Serol.* 5, 119–24(1931).—An aq. soln. of transparent gum arabic can be applied with success as a film cover to all microscopical stained smears, perhaps even to histological and anatomical films. The gum recommended is the Gee Wee gum. Take 1 part of gum and 1.5–2 parts of H_2O, make slightly alk. with *N* NaOH to litmus and sterilize. The soln. can be kept a long time but the reaction must always be alk. The film must be entirely dry. J. C. Jurrjens

A simplified method for the determination of blood cholesterol. Emily M. Day and Adolph Bolliger. *Australian J. Exptl. Biol. Med. Sci.* 7, 41–4(1930).—The method requires less time and app. than others and gives a correlation of ±5% with that of Myers and Wardell, with 0.2 to 1.0 cc. of blood. Blood or plasma is dried at room temp. on two 7 cm. filter papers, folded, placed in 6 in. test tube and covered with $CHCl_3$. The tube is then gently boiled for 15 min. in a beaker of CCl_4 and the $CHCl_3$ decanted and made up to 15 cc. with washings, from which 5 cc. aliquots are taken for analysis as in Myers' method, with 2 cc. Ac_2O and 0.1 cc. concd. H_2SO_4. With 0.2 cc. of blood the drying may be omitted. C. G. King

Rapid determination of blood serum protein. FERNAND KAYSER. *Bull. soc. chim. biol.* **12**, 533–5(1930).—To a mixt. of 25 cc. 95% alc. and 25 cc. acetone, add [illegible] g. MgSO$_4$ in 50 cc. distd. water, let stand 1 hr. and make up to 125 cc. Filter and to an aliquot of the filtrate add 1 cc. formal and 15 drops of 10% AcOH. Bring to boiling and filter, washing the ppt. with small portions of dil. AcOH until free from sulfate. Dry and weigh the ppt. and report globulin by difference.
C. G. KING

The determination of lactic acid in blood. J. LOISELEUR AND R. MOREL. *Bull. soc. chim. biol.* **12**, 538–40(1930).—The method is based upon the procedures of Sakowsky and Clausen (*C. A.* **16**, 2342). To 3 cc. fluoride plasma add 21 cc. distd. water and 2 g. CaO, let stand a few min., add 6 cc. satd. $CuSO_4$, let stand 1 hr. with occasional shaking, and centrifuge. Det. lactic acid in the supernatant liquid by the Clausen method. Control expts. show that lactic acid can be recovered, that glucose does not interfere, and that the results compare closely with Clausen's when applied to different types of blood.
C. G. KING

Utilization of the Soja hispida seed freed from uricase in the detection and determination of allantoin. R. FOSSE, A. BRUNEL, P. DE GRAEVE, P. E. THOMAS AND J. SARAZIN. *Compt. rend.* **191**, 1388–90(1930).—Under exptl. conditions the uricase of the soy bean was destroyed by heat and also by KCN without affecting the active properties of the allantoinase and urease. The uricase-free substance was then studied for possible utilization in the detn. of allantoin in blood serum and in dog serum. The presence of allantoin in a diln. of $^1/_{100,000}$ can thus be unmistakably detected.
B. S. LEVINE

The use of uroselectan in urography. R. S. E. MORRAY. *U. S. Vet. Bur. Med. Bull.* **7**, 111–6(1931).—A brief review of the developments leading to the evolution of Na 5-iodo-2-keto-1-pyridineacetate. Indications for its use and methods of administration and 3 case reports are given.
B. S. LEVINE

The alkaline decomposition of serine. FLOYD S. DAFT AND ROBERT D. COGHILL. *J. Biol. Chem.* **90**, 341–50(1931).—Serine is decomposed when heated in a strongly alk. soln., among the products formed being NH_3, glycine, alanine, $(COOH)_2$ and lactic acid. An intermediate decompn. product is pyruvic acid. Serine must be absent from solns. in which arginine is being estd. by alk. decompn., but this condition is secured by the pptn. of arginine with phosphotungstic acid. The methods commonly employed for the removal of NH_3 from protein hydrolyzates do not cause any significant decompn. of serine.
A. P. LOTHROP

A reduction in the amount of blood required for the Folin micro method for blood sugar. HAROLD J. JEGHERS AND VICTOR C. MEYERS. *J. Lab. Clin. Med.* **15**, 982–4(1930).—A modification is described of the Folin micro method (*C. A.* **22**, 2762) for the detn. of blood sugar. The quantity of blood required is reduced to 0.025 cc., which may be measured by means of a capillary pipet.
E. R. MAIN

A routine blood chemistry unit. E. G. SCHMIDT. *J. Lab. Clin. Med.* **15**, 1013–6 (1930).—A mech. unit is described for the routine detn. of blood chemistries in the hospital lab.
E. R. MAIN

The preparation of some brominated oils and brominated esters. HELEN L. WILKOFF. *J. Lab. Clin. Med.* **16**, 36–8(1930).—Methods are described for the prepn. of brominated oils and brominated esters suitable for use in röntgenologic work. Sesame oil contg. 40% Br appears to be the most suitable of the brominated oils. The brominated Me esters of the acids prepd. from cottonseed oil, which contain 42% Br, appear to be the most suitable of the esters. The latter have a low viscosity, are pale amber in color and more limpid than the corresponding oils or Et esters.
E. R. M.

Determination of copper in biologic material. J. M. INOUYE AND F. B. FLINN. *J. Lab. Clin. Med.* **16**, 49–51(1930).—An electrolytic method is described for the detn. of Cu in biologic material.
E. R. MAIN

Simultaneous determination of inorganic phosphate, sugar and lactic acid in blood. SERGIUS MORGULIS AND SHERMAN PINTO. *J. Lab. Clin. Med.* **16**, 60–4(1930).—Procedures are described for the detn. of inorg. phosphate, sugar and lactic acid in the trichloroacetic acid filtrate obtained from 3 cc. of blood. The inorg. phosphate is detd. by the method of Kuttner and Cohen (*C. A.* **22**, 606); the sugar, by a modification of the Hagedorn-Jensen method and the lactic acid, by the method of Friedemann (*C. A.* **23**, 3245).
E. R. MAIN

Phosphorus metabolism. I. A system of blood phosphorus analysis. GUY E. YOUNGBURG AND MAMIE V. YOUNGBURG. *J. Lab. Clin. Med.* **16**, 158–66(1930).—

Detailed directions are given for the use of a colorimetric method for the detn. of P, in which the phosphomolybdate formed is reduced with $SnCl_2$. The method is adapted to the detn. of total P, inorg. phosphate P, total acid-sol. P and lipide P in whole blood, corpuscles and plasma. E. R. MAIN

The determination of nonprotein nitrogen in 0.1 cc. of blood. ARTHUR K. ANDERSON AND STACEY F. HOWELL. *J. Lab. Clin. Med.* **16**, 183–6(1930).—A modification is described of the Folin-Wu method for the detn. of nonprotein N which requires but 0.1 cc. of blood. The pptg. agent is a mixt. of Na_2WO_4 and H_2SO_4. The digestion is carried out in tubes graduated at 5 cc. E. R. MAIN

A proposed chemical test for pyrogen in distilled water for intravenous injections. EDGAR B. CARTER. *J. Lab. Clin. Med.* **16**, 289–90(1930).—One hundred cc. of the distd. water is heated to boiling in a clean pyrex beaker and treated with 10 cc. of 10% H_2SO_4 and 0.1 cc. of 0.05 *N* $KMnO_4$. The color of the soln. should not be destroyed by boiling for 10 min. if pyrogens (fever-producing org. substances of bacterial origin) are absent. E. R. MAIN

Acetone as a yardstick for ketosis. ARTHUR T. BRICE. *J. Lab. Clin. Med.* **16**, 291–3(1930).—A method is described by which the Legal test for acetone may be used as a quant. method for the estn. of acetone in the urine. E. R. MAIN

Application of the quinhydrone method for the determination of the p_H of solid medium. WM. STEENKEN, JR. *J. Lab. Clin. Med.* **16**, 316–7(1930).—The quinhydrone method may be used for the detn. of the p_H of agar or other solid media. Small portions (5 × 5 mm.) are ground with 0.2 g. of powd. quinhydrone and the p_H is detd. by use of the Cullen and Biilmann electrode (*C. A.* **19**, 3101). E. R. MAIN

A simple method of estimating "osmic acid," with some applications to cytological technic. R. PALMER. *J. Roy. Microscopical Soc.* **50**, 221–6(1930).—Analysis of solns. of osmic acid is desirable, as indicative of deterioration and also of the amt. taken up by the tissue under treatment. Qual. tests for OsO_4 are available, of which Chugaev's is best. A soln. of OsO_4 or a chlorosmate is heated with thiourea in excess, acidified with HCl. A red color is observable in concns. greater than about 1:1,000,000. The reaction is applied to colorimetric estn., by prepg. a series of standards, which are in sealed tubes. 0.2 cc. of 2% OsO_4, 32 cc. H_2O, 4 cc. of 5% thiourea and 4 cc. of HCl (1/5 concn.) give 40 cc. of a soln. contg. 0.01% OsO_4, from which other standards may be prepd. by dilution. For estn. of an unknown, 0.05 cc. is measured by a capillary pipet, mixed with 8 cc. H_2O, 1 cc. 5% thiourea and 1 cc. of HCl (1/5 concn.), heated to boiling and cooled. The reaction is unaffected by $HgCl_2$ but gives a black ppt. if chromate-fixing agents have been used in the tissue. Data are given for the absorption of OsO_4 during the impregnation of frog kidney. Solns. of OsO_4 keep best in tightly stoppered bottles, so evapn. loss is minimized. C. W. MASON

Hyrax, a new mounting medium for diatoms. G. D. HANNA. *J. Roy. Microscopical Soc.* **50**, 424–6(1931).—Resinous mixts. of aniline, S and HCHO may be prepd., but these are rather deeply colored and do not harden readily. "Hyrax" is "a derivative of naphthalene" (no formula or recipe given) of pale straw color and resinous character, n = 1.82, sol. in benzene or xylene, but not in H_2O or EtOH. It hardens by evapn. of solvent; it may be heated gently and is rendered fluid thereby, without discoloration. Prepd. slides and stained specimens have been permanent for several years, with only slight darkening if exposed to sunlight. Hyrax is very transparent to blue and violet. C. W. MASON

A method for the histochemical detection of iodine. U. HINTZELMANN. *Z. wiss. Mikroskop.* **46**, 486–7(1930).—The tissue is fixed in dil. HCHO and treated with 1% TlOAc. Yellow TlI is formed. Sections are best prepd. by the freezing method, and care should be taken not to dissolve out the TlI by subsequent staining treatments. The yellow color is seen best by reflected light against a dark background. TlOAc is better than Pb salts because no ppt. of chlorides or carbonates interferes, and is much cheaper than Pd salts. C. W. MASON

The fate of fructose in the animal organism. I. Determination of fructose by the diphenylamine method. W. W. OPPEL. *Biochem. Z.* **229**, 85–99(1930).—From a detailed study of the method the following procedure for the detn. of fructose has been worked out: Place a mixt. of 1 cc. of the fructose soln., 0.1 cc. 20% alc. soln. of diphenylamine, and 1 cc. 25% HCl in a test tube for 20 min. in a vigorously boiling water bath. Cool the tube quickly in running water, ext. the color with 2–2.5 cc. isoamyl alc. and after sepn. remove the isoamyl alc. layer and dil. with 30 cc. alc., compare the color with that of a standard fructose soln. treated similarly. Quantities between 0.438 and 0.085 mg. can thus be detd. S. MORGULIS

Determination of the acid elimination in the urine. FRITZ MAINZER AND MARGA

BRUHN. *Biochem. Z.* **229**, 216–32(1930).—Urine was collected under paraffin oil and analyzed immediately. The CO_2 content was detd. in the Haldane app. after 15 cc. urine was equilibrated in a tonometer at 38° with a gas mixt. of known CO_2 content. The total CO_2 was detd. in the Van Slyke app.; the H-ion concn. was detd. with the quinone electrode, while the titratable acidity was detd. by titrating under oil to p_H 7.45 with phenol red as an indicator. Not only the H-ion concn. but the titratable acidity as well depends upon the CO_2 tension of the urine. At acid p_H the error in detg. the urinary acidity is small, but at $p_H > 8.0$ it may become 90–100% of the titration. With the aid of CO_2 tension and total CO_2 values satisfactory corrections may be obtained. On the other hand, the total acid excretion (acid + NH_3 − HCO_3) is largely independent of the abs. value of the CO_2 tension, provided the total CO_2 and acid are detd. under the same CO_2 tension. S. MORGULIS

Analytical studies. XII. LUDWIG PINCUSSEN. *Biochem. Z.* **229**, 233-7(1930); cf. *C. A.* **24**, 4801.—A small extn. app. is described for extg. fat from liquids. A method is discussed for detg. Br in urine. Evap. to dryness 5–10 cc. of urine treated with 6–12 drops NaOH, then incinerate in a Ni crucible over an open flame. Filter the ash soln. into a special distn. app., acidify strongly with H_2SO_4 and mix with 20 cc. 10% $KHSO_4$. Add a 2% soln. $KMnO_4$, drop by drop, from a funnel until a permanent pink color remains and suck cold air through the app. for 1.5 hrs., passing it through 2 wash bottles with about 20 cc. 2% KI soln. At the close of the aeration titrate the KI solns. with 0.01 *N* $Na_2S_2O_3$, 1 cc. of which = 0.799 mg. Br. Another method described deals with the microdetn. of NH_3 and urea by the urease procedure. The removal of NH_3 by aeration is facilitated by adding NaCl, which diminishes its soly. To 2 cc. urine add 1.5 g. NaCl, phenolphthalein and paraffin oil, then 2 cc. 33% Na_2CO_3. Distil at 45° for 20 min. when theoretical results are obtained. In the detn. of urea the addn. of the NaCl does not have any significance. S. MORGULIS

The manometric carbon dioxide determination according to Van Slyke. FRITZ MAINZER. *Biochem. Z.* **229**, 311–4; *Klin. Wochschr.* **9**, 2401(1930).—A 50-cc. pipet is described so constructed that the gas vol. can be read at 0.5, 2.0, 4.0 and 6.0 cc. in the Van Slyke manometric CO_2 app. This is very useful in CO_2 detns. of urine, which often cannot be made in the ordinary app. calibrated only at 0.5 and 2.0 cc. S. MORGULIS

Microdetermination of calcium and phosphorus in blood and tissues. G. WIDMARK AND B. VAHLQUIST. *Biochem. Z.* **230**, 245-52(1931).—Blood, plasma or tissue fragments contg. 0.1–0.2 mg. Ca or 0.05–0.2 mg. P are digested with 0.5–0.75 cc. H_2SO_4 in a small Kjeldahl flask, and when the material is completely charred a few drops of concd. HNO_3 is added and the heating continued until a clear, colorless soln. results. The strongly acid soln. is transferred to a Pt dish, washed with H_2O and the soln. evapd. and then ignited to drive off all H_2SO_4. The residue is taken up in H_2O, transferred to a beaker and warmed on a water bath. One cc. of satd. $(NH_4)_2C_2O_4$ and a drop of methyl red are added, and the reaction is adjusted to p_H 5 with NH_4OH and AcOH. The pptn. is allowed to proceed at least 1 hr. and the material is filtered through a special porcelain rod with suction. The ppt. is washed twice with H_2O. The ppt. is dissolved in 0.5 cc. HCl, heated to 60° and titrated with 0.01 *N* $KMnO_4$. The Ca can be detd. in 2 cc. plasma with an accuracy of 2–3% by this method. For the P detn. the digested material is diluted with 15 cc. H_2O and boiled for 3 min. To this are added 5 cc. 50% NH_4NO_3 and, after renewed boiling, 1 cc. 10% $(NH_4)_2MoO_4$. The mixt. is kept for 2 min. at 80°, and the ppt. is allowed to settle out for an hr. It is filtered again by means of the special porcelain rod, and washed 3 times with ice-cold water. An excess of 0.04 *N* NaOH is now added and titrated with 0.04 *N* H_2SO_4 against phenolphthalein. S. MORGULIS

Microchemical demonstration of lead and mercury in the organism. H. BÜLL. *Biochem. Z.* **230**, 299–303(1931).—The Pb is detd. as $K_2CuPb(NO_2)_6$ which forms a beautiful cryst. ppt. The reaction is sensitive to 0.05 mg. Pb and can be carried out even in the presence of Cd or Hg in a concn. 300 times as great as that of the Pb. Blood, urine or feces is charred at a very low temp., and the charred mass is rubbed up with about 4 times its wt. of a mixt. of equal parts of $KNaCO_3$ and of KNO_3. This is now fused in a porcelain crucible, dissolved in 2 *N* HNO_3 and filtered, if necessary. The soln. is evapd. and the nitrate is decompd. by evapg. several times with 2 *N* HCl. Finally, the residue is taken up in 10 cc. 0.1 *N* HCl, warmed to 60° and H_2S is bubbled through it for 30 min. Then following neutralization with 10 cc. 0.1 *N* NaOH the H_2S is passed for 15 min. longer. After standing for 24 hrs. the ppt. is filtered off, washed with 1% NH_4NO_3 satd. with H_2S, and dissolved in hot dil. HNO_3. After evapn. to dryness the residue is taken up in 3 drops of hot 0.1 *N* HCl, transferred to a microscope

slide, evapd. over an open flame, and treated with a drop of 2% Cu acetate soln. Upon evapn. the residue is treated with a drop of a mixt. consisting of equal amts. of AcOH, satd. NH_4OAc and H_2O to which an equal vol. of satd. KNO_3 has been added. In the presence of Pb small brown or large black crystals appear. Pb is always found in feces where Pb had been ingested, and is never present in the blood unless it has been found in the urine or feces. Hg was demonstrated in the vomitus of poisoned persons by first heating this with concd. HCl and $KClO_3$ until a yellow color developed, when a 3 mm. piece of Cu wire is inserted for 24 hrs. The wire is washed, dried and sealed into a capillary tube. The Hg is distd. off by heating the tube and the droplets of Hg are examd. under the microscope. For urine, this must first be heated with concd. HCl and $KClO_3$, satd. with H_2S and the filtered off ppt. is dissolved in HCl and a crystal of $KClO_3$. This is placed on a microscope slide, carefully evapd. and treated with a droplet of a reagent consisting of $Co(OAc)_2$ and satd. NH_4SCN. Instead of this a small crystal of a mixt. can be added obtained by evapg. an aq. soln. of 2 parts $Co(OAc)_2$ and 5 parts of NH_4SCN. Blue crystals of mercuri-cobalti thiocyanate are formed in the presence of Hg. S. MORGULIS

Microdetermination of the reduced and total glutathione in the liver. JOACHIM KÜHNAU. *Biochem. Z.* **230**, 353–72(1931).—Weigh quickly on a torsion balance about 0.5 g. of fresh liver (or liver kept on ice for not over 1 hr.), cut into several pieces and rub up with a little ignited quartz sand to a fine suspension with 9 cc. 10% CCl_3CO_2H. After leaving this for 5 min. filter the material through a double thickness of Schleicher and Schüll No. 595 in a Büchner funnel. Rinse the mortar with 4 cc. of the CCl_3CO_2H and pour this also through the filter, repeating the washing once more. Pour the fluid into a 100 cc. Erlenmeyer flask. To this add 1 cc. 25% KI and 2 cc. 0.005 *N* I_2 soln. and after 2 min. titrate with 0.002 *N* $Na_2S_2O_3$, using 2 drops of a 1% starch soln. as indicator, make a blank titration, using 19 cc. CCl_3CO_2H, the difference multiplied by 0.62 giving the GSH (reduced glulathione) content in mg. With this procedure the error is ±4%. S. MORGULIS

The degree of oxidation within the animal body under the influence of different conditions. HITOSHI KIMURA. *J. Biochem.* (Japan) **12**, 351–69(1930).—Müller's method (*C. A.* **24**, 393) for detg. the "Vakat O_2" has been used with certain modifications. This method gives a measure of the amt. of O_2 needed to oxidize completely the org. substances excreted through the urine. It consists in oxidizing the urine with H_2SO_4 and KIO_3 at a high temp. and detg. in an aliquot the I_2 set free with KI. In another aliquot the N is detd. by the usual procedure. Also a correction for Cl must be made: 1 mg. Cl is equiv. to 1.207 mg. KIO_3. K. points out that it is necessary first to heat the contents of the flask for 2 hrs. at 180°. The use of 0.5 g. KIO_3 for each 10 cc. urine is recommended, but of herbivorous urine only 5 cc. is taken. Human urine should best be dild. 2–3 times with water. Removal of the thyroid gland causes a diminution in the O_2 consumption, but the degree of oxidation is not altered. Feeding thyroid gland increases the amt. of oxidation, while the degree of oxidation is decreased far below normal. Adrenalectomy diminishes both the N and the total metabolism, but the degree of oxidation is not materially affected. S. MORGULIS

A new microdetermination of bile acids in the bile. SATOSU NAGAKAWA AND HOSABURO FUJIKAWA. *J. Biochem.* (Japan) **12**, 399–410(1930).—When 0.5 cc. of an aq. soln. of bile salts is heated for exactly 2 min. in a vigorously boiling water bath with 2 cc. concd. H_3PO_4 and 2 drops of a 0.6% furfural soln. in abs. alc. a beautiful red color develops suitable for colorimetric study. Prep. a standard from 2 solns., one of which contains 0.01 g. scarlet and 1 g. $HgCl_2$ in 100 cc. and the other 1 g. $K_2Cr_2O_7$ in 100 cc. Mix 5 cc. of the first and 1.5 cc. of the second soln. and dil. with water to 30 cc.; this results in a soln. with a very permanent red color. The color is proportional to the concn. of the bile salts within the range of 5–20 mg. %. This red coloration is probably due to cholic acid, the other bile acids reacting very feebly or not at all. Fats, lecithin, cholesterol and alc.-ether exts. of the brain give neg. results. S. MORGULIS

Methods for the determination of total fixed base, sodium and potassium in urine. A. FØLLING. *Skand. Arch. Physiol.* **61**, 27–31(1931).—For the total base detn. place 2 cc. of urine in a silica dish 7 cm. in diam. and, after the addn. of 4–5 drops 50% H_2SO_4, evap. on a water bath and ash at 600°. After cooling, mix this with 1 g. of wet stannic acid and 3 cc. 35% HNO_3 (make the stannic acid by treating 20 g. Sn shavings with 300 cc. 35% HNO_3 and washing the residue several times with water by decantation, keep the metastannic acid wet in a glass-stoppered jar), stir the mixt. and evap. to dryness. When cool, treat it with 10 cc. of a soln. of 2 cc. HNO_3 in 100 cc. water, to 10 cc. of which add 1 cc. EtOH just before using. Stir the mixt. well and filter through ashless paper. Evap. 5 cc. of the filtrate with a drop of 50% H_2SO_4 in a Pt dish, heating

cautiously at first, then all over to a bright red heat for about 10 min. Dissolve the ash in 15 cc. neutralized water (add 0.02 *N* NaOH to distd. water until a persistent red color to phenol red results). If not all the H_2SO_4 was driven off the color turns yellow and can be brought back to red by the addn. of 0.02 *N* NaOH which is then subtracted from the results. Det. the sulfate by the benzidine micromethod as usual. Det. Na and K separately by removing the Ca and Mg as phosphates through the addn. of NH_4OH. To 10 cc. urine add 10 cc. dil. NH_4OH and, after 4 hrs., filter the mixt. Evap. 4 cc. of the filtrate in a silica dish to drive off NH_4OH, then add 5 drops of 50% H_2SO_4 and carry out the detn. as before for the total base. To another 10 cc. filtrate obtained from urine treated with dil. NH_4OH to remove Ca and Mg add 10 cc. 1% $CeCl_3$. Mix well, filter after 15 min. and use a 4-cc. aliquot to det. the total base. Det. the Na alone as the complex uranyl-Zn-Na acetate salt. To 5 cc. urine add 5 cc. of a $UO_2(OAc)_2$ soln. contg. 27 g. of this salt and 3 cc glacial AcOH in 1 l. of water. Filter off the phosphates after 15 min. To 2 cc. of the filtrate in an 18 × 150-mm. test tube add 4 cc. of reagent made by dissolving 20 g. $UO_2(OAc)_2$, 40 g. crystd. $ZnSO_4$ and 7 cc. glacial AcOH in 180 cc. water and filtering after 2 days. This soln. should not give a ppt. when mixed with an equal vol. of alc. To the mixt. in the test tube add 6 cc. 96% alc. with const. stirring and, after 20 min., filter through a Jena Gerate-glass filter. Wash the tube and the filter 4 times with 3 cc. alc. Now dissolve the ppt. and wash back quantitatively into the test tube with hot water. Transfer to a small Erlenmeyer flask and titrate to a definite red with 0.1 *N* NaOH, using 5 drops 1% phenolphthalein. The cc. 0.1 *N* NaOH/8.77 = 0.1 milli-equivs. Na in 1 cc. urine. Det. the K by difference from the K + Na detn. S. MORGULIS

Determination of ammonia in urine by extraction. GRETA HAMMARSTEN. *Skand. Arch. Physiol.* **61**, 49–63(1931).—The Widmark rocking extractor is used. The NH_3 is liberated from 15–25 cc. urine by 5–10 cc. *N* NaOH and the liberated NH_3 is absorbed in a measured amt. of 0.1 *N* H_2SO_4. The solns. in the 2 communicating chambers are covered with layers of acid-free ether. Half of the NH_3 is absorbed in 340 min. so the shaking is carried out for that period of time and the standard acid is titrated with bromocresol purple as indicator. S. MORGULIS

Colorimetric determination of glucuronic acid in urine of man and rabbits. II. A. OGATA AND T. YAMANOUCHI. *J. Pharm. Soc. Japan* **50**, 1059–75(1930); German abstr. 135–8.—The method of detg. glucuronic acid in aq. soln. (cf. *C. A.* **23**, 4718) was applied to the detn. of glucuronic acid in urine of man and rabbits. F. I. N.

The association of biochemical constituents and of certain cellulosic esters. JEAN LOISELEUR AND LEON VELLUZ. *Compt. rend.* **192**, 159–61(1931).—A method is described for the prepn. of a clear, solid membrane made from proteins, glucides or lipins. It is accomplished by using a carefully selected ratio of certain solvents. *E. g.*, in the prepn. of a casein membrane, 9 g. of dry acetate of cellulose is dissolved in a mixt. of 10 parts (47.6 g.) of acetone and 7 parts (33.4 g.) of abs. MeOH; 1 g. casein is dissolved in 9 g. of formic acid. The 2 solns. are mixed with rapid stirring, then poured on a plate till the solvents evap., when a clear membrane is obtained. By this method, membranes may be made from gelatin, casein, glycogen, gums, glycerides and other biochem. constituents. N. M. NAYLOR

Biological reactions applied to the medico-legal identification of muscles. C. SIMONIN. *Ann. méd. légale criminol. police sci.* **11**, 32–7(1931).—Pptg. serums can be used for the identification of fresh muscle only if they possess a very high activity, and only pos. reactions are conclusive. Expts. with 80 guinea pigs are described and showed that: (1) raw muscle behaves in the same way as blood in regard to anaphylactic reactions; (2) on boiling the muscle loses part of its sensitizing properties. A. P.-C.

The quantitative assay for the testicular hormone by the comb growth reaction. T. F. GALLAGHER AND FRED C. KOCH. *J. Pharmacol.* **40**, 327–39(1930).—Individual variations in response of Brown Leghorn capons to the injection of testis hormone were observed; they were not due to variations in age or wt. of the birds or original size of the comb. The best quant. results were obtained by using a min. daily dose required to produce an increase in growth of 3–7 mm. in 5 days. It is suggested that the strength of the hormone prepn. be expressed in bird units; a unit is defined as the amt. of hormone which, when injected in daily doses for 5 days, yields an av. increase of 5 mm. in length and height of the combs in at least 5 birds. C. RIEGEL

The specificity of the phenol reagent for the selective determination of tyrosine in proteins. VINTILA CIOCALTÉU. *Compt. rend. soc. biol.* **101**, 198–9(1929); cf. *C. A.* **21**, 3210.—The Folin-Denis phenol reagent provides a method for the estn. of tryptophan and tyrosine. An objection to this method for tyrosine has been that the reaction is not sp. In approaching this question from the point of view of the speed

of the reaction, C. first studied the possible interference of the $HgSO_4$. Conclusions: The mercuric tyrosine compd. (I) causes the limits of proportionality to vary greatly, and the $HgSO_4$ diminishes the intensity of the reaction. If the solns. which contain (I) are boiled for ½ hr. with HCl, the proportionality becomes perfect again, but the intensity of the coloration remains feeble. The use of H_2S gives the same excellent results as with tryptophan, but for a complete sepn. of tyrosine the flasks satd. with H_2S should stand stoppered for at least 12 hrs. before filtering; 5 cc. of filtrate is boiled in a 100-cc. graduated flask for 30 min. on the water bath, cooled and treated with the reagent. One mg. tyrosine, without $HgSO_4$, serves as the reference standard. The proportionality is perfect. It is thus possible to det. 0.5–4 mg. tyrosine. J. D. S.

A new clinical method for the estimation of protein in urine. PHYLLIS M. TOOKEY KERRIDGE. *Lancet* **1931**, I, 21–2.—The urine is mixed with a C suspension and C and protein are simultaneously pptd. with trichloroacetic acid. The grayness of the ppt. depends on the amt. of protein, when the amt. of C is const. The tone is compared with standards. The error is 0.025–0.05 g. protein N%. F. B. SEIBERT

Triketohydrindene hydrate as a reagent for albumin, peptone and amino acids. HERMANN GARDNER. *Lancet* **1930**, II, 525–6.—The color reaction with ninhydrin is due to the presence of traces of free NH_3 or of NH_3 ions and is masked by NH_4OH or alkali in excess, and is, therefore, not a reliable reagent for detecting the products of hydrolysis of protein. Water contg. 0.00865% NH_3, or in 1 cc. 0.77 mg. NH_3 N, gives a blue coloration. F. B. SEIBERT

Optimum use of material in biological assays. WARREN W. NICHOLAS. *Bur. Standards J. Research* **6**, 77–87(1931).—If a "characteristic curve" (cf. Trevan, *C. A.* **21**, 2913) representing the effect of increasing amts. of an agent on an organism is known approx., it may be used to det. the actual points on the curve accurately and efficiently Such a curve is obtained by plotting the quantity or concn. of an agent, such as x-rays, ultra-violet light, toxins, inorg. drugs, hormones, vitamins, specific sera, etc., against the percentage of cases in which a given effect such as mortality is produced. The practice of using the same no. of animals to det. each point on the curve is inefficient, as the various points are then detd. with different degrees of accuracy. The point which will be detd. with least accuracy is that at which 0.5 the no. of animals show the given effect. To det. all points with the same degree of accuracy it is necessary to use a max. no. of animals for this point, and a decreasing no. for the points departing from this in either direction. A min. no. of animals will be used where all or none produces the given effect. To det. any 1 point independently, an expt. may be conducted with a small group of animals. From the result it is possible to calc. the value for the given point with the aid of an approx. curve, as well as the probable error of this value. The expt. may be repeated until the probable error lies within the desired limits.
CORNELIA T. SNELL

The study of undetermined carbon and glucidic carbon in normal urines. PAUL FLEURY AND PIERRE AMBERT. *J. pharm. chim.* [8], **12**, 350–64(1930).—The main object was to find a relation between the quantity of glucidic C and undetd. C. Glucidic substances are considered those which not only are pptd. by the Cu-Ba reagent (*C. A.* **24**, 1625) but also are reducers of Hg salts (F. and Marque, *C. A.* **24**, 591, 639). From a sample of urine 3 liquids were prepd. at near 0° for examn.: (1) the urine defecated with Hg salts; (2) the Cu-Ba pptn. filtrate of (1) and (3) the H_2SO_4 soln. of the ppt In each of the 3 liquids were detd. (*a*) total C (Nicloux, *C. A.* **23**, 628), (*b*) total N, (*c*) urea, (*d*) Hg reduction, (*e*) Cu reduction (F. and Boutot, *C. A.* **16**, 4222) before and after hydrolysis. Conclusions: C and N contained in the defecate were completely recovered in solns. (2) and (3), while Hg reduction showed a loss of 40%, Cu reduction 20.9% before and 25.3% after hydrolysis. Therefore the losses of reducing power must be due not to removal by pptn., but to instability of the reducing substance As the Cu-Ba ppt. carried down only 20% C in the form of truly glucidic C (0.710 g. per l. = 1.78 g. dextrose per l.) while the defecate by Cu reduction after hydrolysis showed only 0.717 g. dextrose, *i. e.*, about half as much, the heretofore undetd. quantity of "nonreducing glucide" must be of about the same order as the reducing quantity In addnl. expts., starting from the Cu-Ba ppts., the liquids showed no appreciable rotatory power. They contained Cu-reducing substances, exclusively aldoses (no ketoses), and with $PhNHNH_2$ gave crystals seemingly identical with the glucurosazone of Grimbert and Bernier (*C. A.* **4**, 1497); however, they differ greatly in m. p.
S. WALDBOTT

Determination of biliary salts in bile. I. Gasometric determination in one process. II. Volumetric determination by formol titration. III. Evaluation of biliary sulfur. L. CUNY. *J. pharm. chim.* [8], **12**, 485–98(1930); cf. *C. A.* **21**, 2914,

3211; **22**, 2589, 4559.—**I.** To avoid preliminary gasometric detn. of N in the free amino acids, urea and NH_4OH present, remove these by NaBrO, which liberates their N without affecting the mols. of glycine and taurine cholates. Defecate the bile with hot 95% alc., treat an aliquot of the filtrate with NaBrO, remove excess of this with H_2O_2, hydrolyze the bile salts with NaOH, neutralize with HNO_2 and det. the vol. of N as usual in a ureometer by means of $NaNO_2$ and dil. HNO_2. Calc. the results in terms of g. of N per l. of bile. Make a blank test on the reagents used without bile, deducting any gas vol. formed. **II.** Treat the bile as before with 95% alc., NaBrO and NaOH; then eliminate cholalic acid and carbonates by dil. HCl, filter, neutralize with NaOH (phenolphthalein as indicator), add $BaCl_2$, filter again and acidify slightly. Compare a definite aliquot corresponding to 3 cc. of bile (in tube *B*) with an equal vol. of a blank detn. (tube *T*) prepd. exactly as *B* except that bile is omitted. To both *B* and *T* add 6 drops of phenolphthalein and $Ba(OH)_2$ soln. of exactly known strength ($C \times 0.1\ N$) to pale pink and 10 cc. of neutralized CH_2O. Now add to *T* 0.5 cc. of $Ba(OH)_2$ soln. to bring the soln. to dark red, then det. in *B* the vol. (*n* cc.) of $Ba(OH)_2$ soln. necessary to produce the same tint as in *T*. The content of N (g. per l. of bile) is then $N = (n - 0.5) \times C \times 0.0014 \times 1000/3$. **III.** An adaptation of the *benzidine sulfate method* (*C. A.* **21**, 2145; **22**, 4140) is used. After defecation with alc. and evapn., destroy the org. matter by treatment with HNO_3 and then H_2O_2. Hydrolyze the filtered-off benzidine sulfate (obtained by pptn. in an acetone medium) with boiling water and while hot titrate the free H_2SO_4 with 0.02 *N* NaOH in a bromothymol blue soln. as indicator until a permanently *green* tint is formed, to which the indicator soln. was previously adjusted. Each cc. of 0.02 *N* NaOH indicates 0.00032 g. S. C. prefers the above method I although the capacity of the instrument limits the size of the sample used for analysis. Method II requires experience to read the end points; and double filtration is a disadvantage. Finally, C. quotes the results of Eisenfarb (*Polskiego Archiwum Medycyny Wewnetrznej* **6**, 4(1928)) on comparative detns. of biliary acids in org. liquids by colorimetry (Herzfeld and Haemmerli, *C. A.* **19**, 2965), fluorescence (Raue, *C. A.* **21**, 2710) and gasometry (Chiray and C., *C. A.* **21**, 3211).

S. WALDBOTT

Determination of cholesterol in blood. E. CANALS. *Bull. pharm. Sud-Est; Schweiz. Apoth.-Ztg.* **68**, 49-50(1930).—The av. normal content of blood serum and plasma in cholesterol is 1.5 g. per l. The colorimetric method of detn. by Grigaut (cf. *C. A.* **4**, 2513, 2514; **6**, 497, 1447; **8**, 147) is only approx. accurate. The wt. method by Grigaut for total cholesterol, or better still the technic of Windaus for free and combined cholesterol, is recommended. Details are given for all methods. S. W.

Clinical determination of the albumin-globulin ratio in spinal fluid. WM. G. EXTON AND ANTON R. ROSE *J. Am. Med. Assoc.* **96**, 36-7(1931).—For the detn. of *total protein* equal vols. (1 cc.) of spinal fluid and Exton's protein reagent are mixed and the resulting turbidity is measured in the scopometer For the detn. of *globulin*, equal vols. (2 cc.) of spinal fluid and a satd. soln. of $(NH_4)_2SO_4$ are mixed and let stand a few min. for the globulin to salt out. The mixt. is filtered and the filtrate passed through the same filter until clear, care being taken to drain the test tube thoroughly. The filtrate is an albumin soln. and may be used later if it is desired to ppt. and measure the albumin separately. The salted out globulin on the filter paper is placed in a clean test tube, 2 cc. distd. H_2O poured on the filter paper to bring the globulin into soln. and this is passed thrice through the same filter paper to insure a perfect homogeneous globulin soln. After the funnel has been thoroughly drained, 0.2 cc. distd. H_2O is added in the tip of the filter cone to wash down the globulin that adheres to the tip of the cone. One cc. $(NH_4)_2SO_4$ soln. is added to the globulin soln and mixed. The globulin is pptd. by adding 2 cc. of a satd. aq. soln. of phenol and mixed by gently inverting the tube once. The globulin-phenol ppt. is allowed to stand at least 15 min. and then the turbidity is read in the scopometer sometime between 15 and 30 min. after pptn. Mg. globulin per 100 cc. of spinal fluid is obtained by dividing the junior scopometer scale reading by 4. *Albumin* is detd. by subtracting the globulin from the total protein. If a sep. pptn. of albumin is desired, 1 cc. distd. H_2O is mixed with 2 cc. of the original $(NH_4)_2SO_4$ filtrate and pptd. with phenol as for globulin. The no. of mg. of albumin per 100 cc. of spinal fluid is then obtained by dividing the junior scopometer scale reading by 2.

C—BACTERIOLOGY

CHARLES B. MORREY

The effect of iodine on microbes. J. JADIN. *Compt. rend. soc. biol.* **105**, 461–2 (1930).—Suspensions of *E. typhi* (I), *paratyphosus* B (II) and *paratyphosus* C (Hirsfeld's bacillus) (III) were heated on the steam bath at 56° for 30 min. The suspensions were iodized at 50° for 2–3 hrs. by adding first several drops of Na_2CO_3 soln., then I-iodide soln. until free I_2 was present. The excess I_2 was removed by centrifugation, and the iodized microbes were injected into rabbits to get immune sera. The antigen from the injection of iodized I agglutinated both normal and iodized I (1:4000) but not II or III. Similar specificity was shown by II and III. Iodized microbes, unlike serum proteins, preserve with their antigenic properties all their specificities. B. C. BRUNSTETTER

The action of lipoid solutions upon the growth of acid-fast bacilli. TEOFILIP NYREN. *Beitr. Klin. Tuberk.* **73**, 238–50(1929).—Lecithin from 5 different sources (human, cow, pig, plant and egg) was used in disperse soln.; it favored the growth of tubercle bacilli. Cholesterol had no stimulating influence. Human lecithin retarded the growth of saprophytes. There was no inhibition from lecithin upon cold-blood tubercle bacilli and saprophytes. A no. of the acid-fast bacilli grew upon the lecithin nutrient medium with marked granulations. H. J. CORPER

Biological chemical observations on the tubercle bacillus. V. A. VASSILIOU. *Z. Tuberk.* **54**, 219–26(1929).—Tubercle bacilli were extd. with chloroform and a wax-like dark fraction was obtained in addn. to a second fat-like fraction. Various substances were tested to det. the soly. of these fats. The chem. investigation revealed that the m. p. could not be detd. because carbonization occurred at 280°. Extn. of the substances with ether revealed an absence of fat and the constituents of fat such as glycerol, elain, steatin, etc., were absent. Conclusion: The so-called fat and waxy substances of the tubercle bacillus are not related to fat or wax. The watery ext. of the chloroform emulsion disclosed an aldopentose, however. H. J. CORPER

The chemistry of disinfection. WILDER D. BANCROFT AND G. HOLMES RICHTER. *J. Phys. Chem.* **35**, 511–30(1931).—Disinfection is explained on the basis of the colloidal nature of cells. The first stage of decreasing stability of the cell colloid is assocd. with the phenomena of stimulation; the next stage of reversible coagulation inhibits the activity of the organism (antisepsis), and the final stage of irreversible coagulation brings death to the bacteria (disinfection). These colloidal changes of yeast cells and of certain bacteria were observed experimentally with the ultramicroscope. The chem. concept of disinfection is shown to be unsound because of the inapplicability of the mass action law, the lack of stoichiometrical relations and the abnormal temp. coeffs. Conclusion: Disinfection consists first, of an adsorption of the drug and, secondly, of the coagulation of the cell colloids. MALCOLM DOLE

The reaction of purines to protein in microörganisms. ÉMILE F. TERROINE AND FR. SZUCS. *Ann. physiol. physicochim. biol.* **6**, 129–49(1930).—The content of total N cannot be taken as a measure of protein in micoörganisms. It is, however, true that a given species of bacterium always contains the same purine/protein N ratio. H. EAGLE

Influence of starvation (complete starvation and nitrogen starvation) on the proportion of proteins and of purines in microörganisms. ÉMILE F. TERROINE AND FR. SZUCS. *Ann. physiol. physicochim. biol.* **6**, 157–77(1930).—Either complete or N starvation causes a decrease in the total protein of yeast and of *St. nigra*. Purine and protein N fall concomitantly at first; in later stages, the decrease in protein N is proportionately larger. H. EAGLE

The viability of B. pestis. I. S. TINKER AND G. P. RUDNEW. *Arch. Schiffs-Tropen-Hyg.* **34**, 554–9(1930).—*B. pestis* is not affected by Hayem's soln. or by Giemsa stain 1:10. It is, however, killed by a modified Turk's soln., or by fixation of the smear with EtOH for 5 min.–2 hrs., followed by Giemsa stain. The reagent used for hemoglobin detn. kills it in 45 min. Dried and stained, the organism remains viable for 2 hrs. H. EAGLE

The vibriocidal powers of the water of certain rivers of India. SARANJAM KHAN *Indian J. Med. Research* **18**, 361–5(1930).—Water of the Ganges and Jumna rivers has vibriocidal properties which are completely destroyed by heating at 55° for $^1/_2$ hr. H. EAGLE

The bacteriological diagnosis of tuberculosis. J. MOURIZ. *Klin. Wochschr.* **9**, 2249–51(1930).—Hohn's method was found to be the best for isolating tubercle bacilli from mixed culture. No more than 4–5% H_2SO_4 should be used; a potato-egg medium

was found to be the best. A special tube was devised to keep the medium moist.
H. EAGLE

Formation of hydrogen peroxide by lactic acid bacteria. ALFRED BERTHO AND HANS GLÜCK. *Naturwissenschaften* 19, 88(1931).—H_2O_2 is formed in oxidative metabolism by the facultative, anaerobic, catalase-free lactic acid producers *Bact. delbrücki*, *B. iugurt* and *B. acidophilus*. The O consumption was followed in Barcroft manometers with glucose as "donor." HCN, 0.0005 mol., was without influence. The H_2O_2 was detected with Ti sulfate and detd. as Ce peroxide (Wieland and Rosenfeld, *C. A.* **24**, 2155) or by direct titration. Generally the theoretical amt. from $2H + O_2 = H_2O_2$ was found. Catalase addn. reduced the amt. of H_2O_2 to half. If the H_2O_2 was not bound during the reaction, its increasing concn. damaged the cells and resulted in decreased total production. The conditions were about as follows: 3 cc. bacterial suspension of 10 mg. dry substance, 3 cc. 0.1 *M* glucose, 3 cc. 0.2 *M* borate buffer of p_H between 8 and 9, 1 or 2 cc. 0.002 *M* cerous sulfate were added together to give an initial p_H of 8.2 to 8.3. For *Streptococcus casei*, which also respires unhampered by HCN, no H_2O_2 formation was found. B. J. C. VAN DER HOEVEN

The use of small additions of acid for increasing the germicidal action of E. C. on bacterial spores. C. S. RAM AYYAR. *Agr. J. India* **25**, 213–9(1930); cf. *C. A.* **24**, 5328.—Spores of refractory bacteria, such as *B. subtilis*, *B. albolactus* and *B. mesentericus*, were practically completely destroyed after 30 min. contact with a soln. contg. 0.2% of E. C. (a special hypochlorite soln. contg. 2% of available Cl) and 0.05% of a N soln. of citric acid. With a 0.2% soln. of E. C. alone the spores were not destroyed even after 60 min. contact, although the no. was reduced to a considerable extent. K. D. J.

Remarks on the composition of peanut meal peptone and its use for the culture of pathogenic bacteria. ALBERT BERTELOT, G. AMOUREUX AND DENIS PETIT. *Bull. soc. chim. biol.* 12, 1029–30(1930).—Analysis is given of a pepsin (I) and a pancreatic peptone (II), illustrating differences depending upon the method of prepn. I gave good toxin production and II did not, although both gave good growth with *B. tetanus*.
C. G. KING

Physical difference among bacteriophages. F. M. BURNET. *Australian J. Exptl. Biol. Med. Sci.* **7**, 27–35(1930).—Bacteriophages from *Salmonella*-dysentery groups of bacilli fell within 2 groups with regard to the difference in heat stability and ascension of filter paper. C. G. KING

Balanced salt action as manifested in bacteriophage phenomena. F. M. BURNET AND MARGOT MCKIE. *Australian J. Exptl. Biol. Med. Sci.* **7**, 183–98(1930); cf. *C. A.* **24**, 5787.—Bacteriophage (I) dild. in a soln. of Na, K and NH_4 salts were inactivated by heating 1 hr. at 60°, but the presence of Ca, Ba or Sr salts partially or completely prevented such action In the absence but not in the presence of bivalent cations or broth, Janus green, toluidine blue and methylene blue inactivated a dil. soln. of I. Different types of I show characteristic individual differences in sensitivity toward inactivating and protecting substances. The effects related to the Na:Ca balance are like those of living protoplasmic structure. Electrophoretic expts. indicate a decrease in effective size of I in the presence of excess Ca ion. C. G. KING

The electrical behavior of bacteriophages. F. M. BURNET AND MARGOT MCKIE. *Australian J. Exptl. Biol. Med. Sci.* **7**, 199–209(1930).—In electrophoretic expts. 20 types (salmonella, dysentery and staphylococcus) of bacteriophage all showed a neg. elec. charge. The migration rate and adsorption of proteins (globin and gelatin) varied greatly. In one case cathodic concn. was obtained for a type which acted only on rough strains and was not sensitive to methylene blue, toludine blue or Janus green.
C. G. KING

Oligodynamic dilutions. JULIUS MEYER. *Chem.-Ztg.* 55, 85–6(1931).—The term "oligodynamic" as used in biology and medicine is a misnomer. It was used originally to designate germicidal telekinesis of metals such as Ag or Cu plates placed in aquaria or flower vases. At present under this term is included such germicidal action as is manifested by extremely high dilns. of metallic salts, despite the fact that the phenomenon of telekinesis is entirely absent. The dilns. with which the biol. and medical investigators are experimenting often are extremely high from the point of view of the analytical and phys. chemist. For example, K. König (cf. *C. A.* **22**, 4177) worked with dilns. of $AgNO_3$ and $Pb(NO_3)_2$ varying from 10^{-2} to 10^{-29}. For $Pb(NO_3)_2$ in a 10^{-29} diln. 55,000 l. of the soln. contains 1 mol. of the reagent and for $AgNO_3$ 28,000 l. contains 1 mol. of the reagent. Results obtained from work with such dilns. are scientifically valueless since such dilns. cannot be distinguished from water of the highest purity.
B. S. LEVINE

Experiments on bacteriophage adsorption by vulnerable bacteria. CLAUDE P.

BROWN AND FRANK GEMAR. *U. S. Vet. Bur. Med. Bull.* 7, 224–9(1930).—The expts. show that it is possible to adsorb bacteriophage obtained from sewage by using a vulnerable organism (*E. coli*) against which it is actively lytic. Temp. control is necessary in order to bring about the adsorption of bacteriophage when the organism against which it is actively lytic is used for this purpose. A temp. as low as 25° still permits lysis, while 16° or lower prevents lysis. B. S. LEVINE

Disinfection. II. The manner of death of certain bacteria and yeasts when subjected to mild chemical and physical agents. GEORGES KNAYSI AND MORRIS GORDON. *J. Infectious Diseases* 47, 303–17(1930).—The order of death of *E. coli* and of *Schizosaccharomyces pombe* when produced either by chem. or by phys. agencies is detd. by the distribution of resistance among the cells. That this distribution is not uniform among a culture of microorganisms is shown by the structure of the death curves The similarity in results obtained with *E. coli* and *S. pombe* does not justify the theory advocating a difference in the order of death between small and large cells. **III. The taking up of iodine by yeast cells.** *Ibid* 318–21.—The cells of *Saccharomyces cerevisiae* take up I from its aq. solns. according to the adsorption isothermal. These results are in agreement with microscopic observations which show that the colloidal structures of the cells, and especially the membrane, take up I to a great extent and give up much of it on dilu. When $HgCl_2$ is used instead of I, the adsorbed salt may be pptd. as HgS. The membrane, with its high adsorptive power, becomes black, while the rest of the protoplasm becomes gray only after more prolonged standing. This suggests that the mechanism of disinfection is closely related to that of dyeing and tanning. JULIAN H. LEWIS

The use of acid fuchsin in Russell's triple sugar medium. G. D. CUMMINGS. *J. Infectious Diseases* 47, 359–66(1930).—Undecolorized acid fuchsin is recommended for use in the Russell medium because of its chem. stability, ease of prepn., ability to give clear-cut reactions and lack of inhibitory effect. The use of undecolorized acid fuchsin would eliminate the variety of methods for the prepn. of Andrade indicator now to be found in the literature. JULIAN H. LEWIS

The growth and toxin production of Corynebacterium diphtheriae in synthetic media. MARY E. MAYER. *J. Infectious Diseases* 47, 384–98(1930).—Diphtheria bacilli can be adapted to grow and produce potent toxin in a modified Braun and Hofmeier synthetic medium. The chief modification was of the N-bearing constituents The cystine content was increased fourfold, asparagine or NH_4 succinate replaced the Na aspartate, and glycine was added. It appears that the medium must provide not only nutrients for rapid growth and pellicle formation, but these nutrients should also favor the appearance or maintenance of the toxigenic variants that occur in consequence of a dissociative process. JULIAN H. LEWIS

Hexylresorcinol in experimental tetanus. GEORGE E. COLEMAN. *J. Infectious Diseases* 47, 410–5(1930).—Hexylresorcinol S. T. 37, when mixed with tetanus toxin in 16.6% soln., is capable of neutralizing 10 and less than 100 minimal lethal doses. It is bactericidal for the vegetating forms of tetanus bacilli within 0.5 hr. *in vitro*, but does not kill resistant spores in 12 hrs. When injected into the devitalized or necrosed tissue of guinea pigs infected with tetanus spores, it is without action in modifying the course of the disease. JULIAN H. LEWIS

Decomposition of urea by Proteus. ALEXANDER A. KAY, WM. M. GIBBS, ARTHUR W. WALKER AND RUTH E. JUNG. *J. Infectious Diseases* 47, 490–502(1930).—The destruction of urea by *Proteus* in various media was studied. Urea does not meet the N requirement of the organisms and the inference is warranted that the action on urea is only incidental to the metabolism of the bacteria and is not concerned with its vital needs. The enzyme responsible for urea destruction is of endocellular nature since $CHCl_3$-killed, washed and dried organisms are active. JULIAN H. LEWIS

The antagonistic substances formed during bacterial fermentation. B. KLEIN. *Z. Immunitäts.* 66, 530–42(1930).—In culture media contg. carbohydrates bacteria form antagonistic substances that behave like antibodies in that they produce agglutination and bacteriolysis of whole bacteria and give precipitin and complement-fixation reactions with bacterial exts. These reactions are, however, not sp. The agglutination is due to acids formed during fermentation. The antagonistic substances are formed not only in lab. media but also in natural and com. processes involving fermentation such as the curdling of milk and the manuf. of beer, wine and cheese. J. H. L.

The antiseptic properties of uroselectan. RUGGERO ASCOLI. *Minerva med.* 1930, II, 415–7.—Uroselectan, the Na salt of 5-iodo-2-keto-1-pyridineacetic acid, in concns. of 10–20% retards the growth of *E. coli* and *Staphylococcus* in urine. The inhibition is

more marked at a concn. of 30%, but even a concn. of 40% fails to kill the organisms. The substance, therefore, has bacteriostatic but no antiseptic power. P. M.

Peroxidase in relation to bacterial growth with special reference to the influenza bacillus. LUCILE R. ANDERSON. *J. Bact.* **20**, 371–9(1930).—*B. influenzae*, hemolytic and non-hemolytic, and *B. hemoglobinophilus-canis* do not produce peroxidase. *B. parainfluenzae* produces it under both aerobic and anaerobic conditions. Not one of 13 anaerobes tested produced it according to the benzidine reaction. Of 44 aerobes tested all but 4, two of which were streptococci, gave a positive reaction. Banana reacts positively to the benzidine test. The "X-factor" of Fildes seems to be associated with peroxidase. JOHN T. MYERS

Micrococcus niger, a new pigment-forming anaerobic coccus recovered from urine in a case of general arteriosclerosis. IVAN C. HALL. *J. Bact.* **20**, 407–15(1930). JOHN T. MYERS

The effect of the oxidation-reduction character of the medium on the growth of an aerobic form of bacteria. W. P. ALLYN AND I. L. BALDWIN. *J. Bact.* **20**, 417–40 (1930).—This factor exerts an important influence on the growth and behavior toward atmospheric O of certain aerobic bacteria (*Rhizobium*). In agar shake cultures these organisms establish thin zones of growth, the level of which depends on the oxidation-reduction character of the substrate. This also dets. in part the ability to initiate growth. By reducing with appropriate concns. of cystine a medium which is slightly too oxidized for these organisms, it is possible greatly to increase the no. of sources which develop into colonies in Petri dish cultures. Hence this is important in making plate counts. The organisms are able to make slight adjustments if the media are too oxidized. The introduction of sand, finely divided filter paper, etc., into a liquid medium which was too oxidized to permit growth overcame the condition, probably because of the trapping of small vols. of medium where the organism could make the necessary adjustments, as suggested by a lag period interpreted as time required for this adjustment. The bacteriostatic effect of certain oxidizing and reducing substances seems due in part to the poising of the medium at an unfavorable potential. Their toxicity depends largely on concn. in relation to the oxidation-reduction potential of the system. Similar concns. were inhibitory under one set of conditions and stimulatory under another. J. T. M.

A marine denitrifying organism. BLODWEN LLOYD. *J. Bact.* **21**, 89–96(1931).—A denitrifying organism was isolated from sea water off the Scottish coast, and denitrification curves were constructed. JOHN T. MYERS

The effect of temperature upon the production of hydrogen sulfide by Salmonella pullorum. RALPH P. TITTSLER. *J. Bact.* **21**, 111–8(1931).—An incubation temp. of 30° is optimum, and temps. above 37° inhibit H_2S formation by *S. pullorum*. Slight quant. differences were noted between aerogenic strains at 30°. The ability to produce H_2S parallels the ability to produce gas from carbohydrates. Difco Pb agar is satisfactory for demonstrating H_2S formation. JOHN T. MYERS

A modified Loeffler's blood serum medium useful in the routine health department examination for diphtheria and streptococcus infections. LEON S. MEDALIA, KARL R. BAILEY AND CATHERINE ATWOOD. *J. Bact.* **21**, 118–37(1931).—Loeffler's medium is modified by the addn. of 4.5% of *N* NaOH, yielding a final p_H of 7.6; bromothymol blue is used as an indicator. JOHN T. MYERS

An instance of pigment formation by B. pestis. A. BESSONOVA AND M. LOCHOV. *Zentr. Bakt. Parasitenk.*, I Abt., **119**, 35–8(1930). JOHN T. MYERS

A polysaccharide-building streptococcus. J. OERSKOV. *Zentr. Bakt. Parasitenk.*, I Abt., **119**, 88–93(1930).—A substance analogous to the polysaccharides of the pneumococcus was found. JOHN T. MYERS

Bacteria which destroy blood pigment. (Studies with the help of bacteria which form hydrogen peroxide on heated blood plates. K. BINGOLD. *Zentr. Bakt. Parasitenk.* I Abt., **119**, 97–100(1930).—Pneumococci, *Streptococcus mucosus*, *S. viridans* and to a lesser degree *S. pyogenes* can split oxyhemoglobin, methemoglobin or hematin to substances of simpler constituents. This seems to be due to H_2O_2 formation. This can occur only in the absence or the presence of minute amts. of catalase. JOHN T. MYERS

Changes in virulence and hemolytic power produced in hemolytic streptococci by growth in hematin agar. K. BINGOLD AND K. BACH. *Zentr. Bakt. Parasitenk.*, I Abt., **119**, 100–3(1930).—Growth in hematin agar decreases virulence and hemolytic power. JOHN T. MYERS

The pigments of timothy grass bacilli. ERWIN CHARGAFF. *Zentr. Bakt. Parasitenk.*, I Abt., **119**, 121–3(1930). JOHN T. MYERS

The phenomenon of hemolysis through the action of bacteriophage. ELISABETH BECHTEL. *Zentr. Bakt. Parasitenk.*, I Abt., **119**, 340–9(1931). JOHN T. MYERS

Cytological observations on the dissociation process in B. pestis. M. POKROVSKAYA. *Zentr. Bakt. Parasitenk.*, I Abt., 119, 353–61(1931).—A nucleus of chem. structure analogous to that in higher forms is demonstrable in certain phases of bacterial development. JOHN T. MYERS

The disinfecting action of simple organic mercury compounds. GERTRUD MEISSNER. *Zentr. Bakt. Parasitenk.*, I Abt., 119, 375–9(1931).—There are halogen Hg alkyl compds. which have a higher killing power for staphylococci and anthrax bacilli than does $HgCl_2$. The growth-inhibiting power of Me, Et, Pr, Bu and Am Hg compds. is about 25–1000 times higher than that of $HgCl_2$. The action of the higher members of the series is weak or nil. Cl and Br salts are about equal in action, but I salts are weaker. The killing action is also better than that of $HgCl_2$. The hydroxides have a much weaker action than the halogen salts. Anthrax spores were more susceptible than staphylococci. JOHN T. MYERS

The influence of alkaloids on the metabolism of Bac. pyocyaneus. T. H. AMAKO. *Zentr. Bakt. Parasitenk.*, I Abt., 119, 464–72(1931).—Cocaine, nicotine, physostigmine, pilocarpine and strychnine inhibit methylene blue reduction in proportion to their concn. Atropine and morphine inhibit only at moderate concns. (0.1 to 1.0%), not above or below. JOHN T. MYERS

The influence of plant growth on the activity of root bacteria. GERTRUDE GRÄF. *Zentr. Bakt. Parasitenk.*, II Abt., 82, 44–69(1930).—The greatest activity of the N-fixing root bacteria is concurrent with greatest plant growth. NH_3 production in soil is also greater during plant activity. JOHN T. MYERS

The fermentation of pentoses by certain propionic acid bacteria. MARIAN FOOTE, E. B. FRED AND W. H. PETERSON. *Zentr. Bakt. Parasitenk.*, II Abt., 82, 379–89(1930).—In common with the majority of organisms, the propionic acid bacteria do not ferment the pentoses as readily as the hexoses. Out of 20 cultures tested, 13 fermented arabinose and only one fermented xylose. The fermentation of pentoses as compared with glucose is marked by a decrease in the percentage of volatile acids and an increase in non-volatile acids. The ratio of propionic acid to acetic acid is decreased. The non-volatile acids consist of lactic and succinic. The latter was identified by its m. p. and the Ba content of its salt. The succinic acid is probably derived from the carbohydrate rather than from the yeast water. JOHN T. MYERS

The influence of high dilutions of quinine on the bacterial flora in hay infusion. M. FEILER. *Zentr. Bakt. Parasitenk.*, II Abt., 83, 63–8(1931).—Quinine at a concn. of about 10^{-10} *M* favors the growth of *B. proteus*. *Paramecium* is stimulated at a concn. of about 10^{-18}. JOHN T. MYERS

The lactic mannitic fermentation of sucrose. BOLCATO VIRGILIO. *L'ind. saccarif. ital.* 22, 427–32(1929).—Partial anaerobiosis is a needed condition for the activity of mannitic enzymes. A smaller amt. of mannitol with aerobic fermentation is compensated for by more lactic and acetic acids. Fermented juices defecated with basic Pb acetate gave, with Bertrand's liquid after 1 day, polarization of 7.60 and 0.528% invert sugar; after 2 days, polarization of 3.70 and 4.000% invert sugar; after 3 days, polarization of 2.20 and 3.040% invert sugar; after 4 days, polarization of 2.70 and 1.630% invert sugar. A variation in the quantity of invert sugar influences the saccharimetric value, rendering it unsuitable for a control of the fermentation process. This is best conducted by considering the principal products: lactic acid (45% of the sucrose), AcOH (12–5%), mannitol (30–5%). AcOH is detd. by adding H_2SO_4 and distg. in a current of steam; lactic acid is detd. by subtracting AcOH from total acid. For detg. total acid the fermented liquid is neutralized with $CaCO_3$; in 1 cc. of the clear liquid Ca is pptd. with NH_4 oxalate and the oxalic acid titrated with 0.1 *N* $KMnO_4$. From this the Ca and lactic acid are detd. Mannitol is best detd. by Gayon and Dubourg's method of crystn. from alc. at 85° and weighing. The estn. is preceded by an alc. fermentation for eliminating the remaining sugars. The yeast has only a slight action on the mannitol. If samples are taken regularly from the beginning of fermentation it is noted that, while the lactic acid is formed continuously with a regular speed, the mannitol is all formed within the first 4–5 days. In the same time nearly all the AcOH is formed. The same juices with the sucrose inverted by warm H_2SO_4, filtered and submitted to fermentation, in 2 days show a change in the polarization from neg. to pos., denoting a more rapid consumption of levulose than glucose. The destruction of levulose is very rapid, as is the production of mannitol and AcOH, and continues until all the mannitol is formed. Despite the consumption of glucose (shown by the increase in lactic acid) the pos. polarization continues to rise and reaches its max. with the total disappearance of levulose and arrest in the production of mannitol. After this the pos. polarization is gradually reduced by the transformation of glucose into lactic acid. This is caused by

the high neg. value of the sp. rotary power of levulose, $[\alpha]_D = -92°$, in comparison with the pos. value of glucose, $[\alpha]_D = +52°,5'$, and the lower fermentation speed of glucose with regard to levulose. R. SANSONE

The indole titer of Gersbach. E. L. KRUGERS DAGNEAUX. *Chem. Weekblad* **28**, 66–7(1931).—The fact that the colon bacilli do not give the indole reaction after some time is not a disadvantage as it shows that the pollution occurred long ago and that there is no danger of typhoid contagion. E. SCHOTTE

The action of alkylresorcinols on phytopathogenic bacteria. C. STAPP. *Angew. Bot.* **12**, 275–289(1930); *Rev. Applied Mycol.* **10**, 46.—The effect of varying concns. of phenylethylresorcinol and of hexylresorcinol on phytopathogenic bacteria depends so greatly on the media in which the bacteria are grown that no conclusion as to the toxic action of these substances on phytopathogenic bacteria within the host can be drawn by their effect on the same organisms on artificial media. Where potato tubers were used as the media for *B. phytophthorus* concns. of 0.2% of hexylresorcinol and 0.3% of phenylethylresorcinol were necessary to inhibit the growth of the organism, whereas lab. tests showed that concns. of 0.08% of either killed the bacteria when free of media. Seven media and 7 bacteria were studied. ODEN E. SHEPPARD

Gas-metal electrode potentials in sterile culture media for bacteria. ELDON M. BOYD AND GUILFORD B. REED. *Can. J. Research* **4**, 54–68(1931); cf. *C. A.* **23**, 3411.—The work of French and Kahlenberg on gas-metal electrode potentials suggested that the potentials obtained at inert metal electrodes immersed in growing cultures of bacteria, and generally regarded as an oxidation-reduction phenomenon, might be of a similar type. This was tested by passing air, H, N and CO_2 through sterile beef broth and observing the potentials developed at Pt, Au and Hg electrodes. It is shown that air causes a rise in potential at all 3 electrodes; H_2 causes a marked fall in potential at the Pt and a slight change at the Au and Hg electrodes; N and CO_2 cause little or no change in the potential at the 3 electrodes. These changes are in agreement with French and Kahlenberg's results except with the Hg electrode which is shown to react chemically with the broth. J. W. SHIPLEY

The mechanism of bacterial action. J. H. QUASTEL. *Trans. Faraday Soc.* **26**, 853–64(1930).—A summary of the work on the dehydrogenases of resting bacteria. The theory previously developed (*C. A.* **22**, 249, 4137), of the localization of dehydrogenation reactions on sp. areas of cell surface, is outlined. K. V. THIMANN

Increased bactericidal effect of inorganic compounds in the presence of x-rays (NORRIS) **7**. Red colorations on salted hides and a comparison of the growth and survival of halophilic or salt-loving organisms and some ordinary organisms of dirt and putrefaction on media of varying salt concentrations (ROBERTSON) **29**. The microbiological aspect of peat formation (THAYSEN) **8**.

Handbuch der pathogenen Mikroörganismen. 3rd ed., edited by WILHELM KOLLE, RUDOLF KRAUS AND PAUL UHLENHUTH. Band. VII, Tl. 2. Jena: G. Fischer. Berlin and Vienna: Urban & Schwarzenberg. Pp. 753–1752. M. 108. Cf. *C. A.* **25**, 983.

THOMAS G. PHILLIPS

Phototoxic substance from Hypericum crispum. Z. MÉLAS IOANNIDÈS. *Arch. Inst. Pasteur Hellén.* **2**, 161–165(1928).—In an attempt to isolate the phototoxic substance from *Hypericum crispum*, 0.16 g. of a red, amorphous substance, slightly sol. in water and giving a characteristic spectrum, was obtained from 100 g. of the dried plant. B. C. A.

The phototoxic pigment of Hypericum crispum. ZOÉ MÉLAS IOANNIDÈS. *Compt. rend. soc. biol.* **105**, 349–51(1930); cf. preceding abstract.—The isolated pigment of *Hypericum crispum* when inoculated into white rats photosensitized the animals in the same way that ingestion of the fresh plant does. The pigment was obtained in cryst. form by extg. the dried plants with 0.3% Na_2HPO_4, and treating the filtrate with AcOEt. The 2 phases were sepd. by satg. the aq. layer with Na_2CO_3. The AcOEt soln. of the pigment was purified by washing 3–4 times with satd. Na_2CO_3 soln., then with H_2O; the filtered soln. was concd. by distn. to 60 cc., and treated with 240 cc. of ether. The pigment was extd. by shaking with 0.3% Na_2HPO_4. The pigment seps. in amorphous

form on acidification with KH_2PO_4 soln. Slow acidification, obtained by diffusion without agitation from KH_2PO_4 crystals, resulted in 0.05 g. of brick-red crystals. These are insol. in $CHCl_3$, CS_2 and C_6H_6, very slightly sol. in ether, fairly sol. in MeOH, EtOH and AcOEt and extremely sol. in acetone and pyridine. All the solns. are strongly fluorescent, and are bright red in color. The pigment is pptd. in a brick-red colloidal form by the addn. of Na_2CO_3, or as a grayish green ppt. on the addn. of NaOH. It is also pptd. by dil. acids which seem easily to alter it. The following absorption spectra data were obtained on a soln. of 0.1 g. of pigment in 5000 cc of alc.: 4-mm. layer, band 1,599–588–586, band 2,553–545; 20-mm. layer, band 1,605–587–575, band 2,558–547–545, band 3,513–548; 10-mm. layer, band 1,612–573–570, band 2,562–530–528, band 3,515–505 (progressive absorption at the extreme violet of the spectrum, 485).

B. C. BRUNSTETTER

Wood-pentosan. I. K. NISHIDA AND T. TAKAGI. *Cellulose Ind.* (Tokyo) **6**, 170–3(1930); *Abstracts*, 32–3.—Woodmeals from a no. of different coniferous and deciduous trees were extd. with 5% NaOH soln., the ext. was treated with Fehling soln. in order to sep. pentosan as the Cu compd., the latter was decomposed with HCl, and the yield and compn. of the pentosan were detd. The pentosan content (from the Cu compd.) of the deciduous woods examd. is found to be characteristic, while coniferous woods contain much smaller quantities of pentosan. Frequently the wood pentosan was converted into 2 different modifications; deciduous woods contain both the α- and β-varieties, while only the α-type is present in coniferous wood. The compn. of the β-pentosan (% xylan, etc.) from the deciduous woods examd. is given; that of the α-variety will be given in part II. B. C. A.

Micro-incineration of diatoms without carapace. E. BACHRACH AND MME. PILLET. *Compt. rend.* **190**, 1442–3(1930).—No SiO_2 was detected in the hyaline body of the diatom *Novicula* without carapace. The ash contained Ca. B. C. A.

Differentiation between good and poor germinative capacity of seeds by chemical means. H. O. PAECH. *Diss. Agr.-Chem. Inst. Univ. Breslau* 1929.—The germinative activity of seeds is closely related to their dehydrogenase activity. Of numerous colorimetric methods for the detn of the latter, the most satisfactory is that using *m*-dinitrobenzene. Comparative tests should be made on the same day with freshly ground material. B. C. A.

Action of a sudden withdrawal of nutrient salt solution from corn seedlings. G BERTHOLD. *Z. Botan.* **23**, 94–131(1930).—Corn seedlings, grown for a time in nutrient salt solns., were transferred to distd. water, and progressive anatomical and physiol. changes were observed. R. C. BURRELL

The nature of chemodinetical stimulation and the differences in swelling produced by *l*-asparagine. HANS FITTING. *Z. Botan.* **23**, 328–60(1930).—Plasma streaming in leaf sections was studied and the stimulating effect of dil. solns. of asparagine noted. These dil. asparagine solns. readily become inactivated as the result of bacterial action. R. C. BURRELL

Chlorophyll changes in barley. HARALD NILSSON. *Arkiv. Kemi, Mineral. Geol.* **10A**, No. 12, 34 pp.(1930).—No essential differences in activity were shown between the normal green chlorophyll in homo- or heterozygotes or the chlorophyll-deficient white homozygotes in barley seeds. The O_2 utilization of the intact green embryo and of certain organs as the leaves, roots and endosperm is greater than that of the white parts. No difference between the homo- and heterozygotes could be detd. in this respect. The earlier results which showed no relationship between O_2 utilization and catalase activity are confirmed. Higher O_2 consumption occurred in all cases with chlorophyll-contg. leaves than with chlorophyll-deficient ones. The presence of KNO_3 was without effect on the O_2 utilization. Only slightly lower ash content was found in the chlorophyll-deficient leaves than in the green ones. H. J. DEUEL, JR.

Plant proteases. XVI. The activation of animal and plant proteases by glutathione. W. GRASSMANN, O. V. SCHOENEBECK AND H. EIBELER. *Z. physiol. Chem.* **194**, 124–36(1931); cf. *C. A.* **24**, 868.—Zoökinase, the natural activator of animal proteases, has recently been shown by Waldschmidt-Leitz (*C. A.* **24**, 5316) to be identical with glutathione. A similar identification of the phytokinase of yeast is now reported. The activator of yeast proteinase is rapidly liberated by autolysis in the presence of a cell poison, the greater part passing into soln. during the first hr. The liberation of proteolytic enzyme, on the other hand, is hardly appreciable during the 1st hr. and requires 24 hrs. for completion. The sepn. of enzyme and activator is therefore a comparatively simple matter. The 1st fraction, which has no enzymic activity, contains the glutathione of the yeast and has the property of activating the inactive enzyme to the full activity attainable by treatment with HCN. Boiled yeast ext. shows the

same behavior. Fractionation of the crude activator soln., according to the procedure for purification of glutathione, yields fractions in which the activating capacity and the glutathione content are strictly parallel. The activity of the crude activator soln. is therefore due to its glutathione content. Since cysteine and glutathione must be in their reduced form to activate papain and cathepsin, it would appear that the natural SH system effects an intimate connection between respiration and proteolysis. Hydrolytic processes are commonly assocd. with anaerobic conditions, while synthetic processes are performed by the cell during active respiration. In the functioning cell, which is abundantly supplied with O, the glutathione would be present in its disulfide form, and hence the cathepsin for the most part would be in its inactive form. The cell would thus be protected from autolysis. However, there is reason to believe that the activation phenomena cannot be attributed exclusively to glutathione, since yeast proteinase undergoes self-activation under conditions which preclude the intervention of glutathione. A. W. Dox

Plant microchemistry. L. Rosenthaler. *Pharm. Zentralhalle* **72**, 81–5(1931).—An address. W. O. E.

Growth and absorption by oats in relation to varying concentrations of calcium and sodium in the nutrient solution. C. Philipson. *Svensk Bot. Tid.* **24**, 155–262 (1930); *Physiol. Abstracts* **15**, 263.—The relation of dry wt. of culture to compn. of the nutrient soln. is shown graphically for 2 periods of growth: (*a*) 1–3 weeks, involving 6 harvestings; (*b*) 2 months and for mature plants and seeds. The dry-wt.-time curves for the first 3 weeks follow V. H. Blackman's formula. N content and ash content follow the same course as the dry wt.; Ca content increases more rapidly. Changes in Ca utilization are involved in the antagonism between Ca and Na; it is probable that these changes are due partly to alteration in permeability of cell membranes. G. G.

The proteins and vitamins in the embryo of the soy bean. Sajiro Ohtomo. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 15–7.—The embryo constitutes 2.09% of the soy bean. It contains moisture 4.47, crude protein 42.24, protein 35.75, crude fiber 2.96, ash 3.45, crude fat 9.46, non-nitrogenous ext. 37.42 and pentose 5.7%. Of the total N, 78.8% is sol. in H_2O, 8.61% in NaCl soln. and 5.22% in NaOH soln.; 78.68% of the N is present as globulin, 6.64% as albumin, 9.12% as proteose and 5.56% as nonprotein. On the basis of dry matter N is distributed as follows: total N 7.08, sol. in 20% HCl 6.90, amide 0.69, humin 0.21, arginine 1.32, histidine 0.23, lysine 0.55, cystine 0.09, amino 4.86%. The embryo is richer in vitamins *A* and *B* than is the endosperm. V. F. Harrington

Absorption and utilization of potassium by plants. R. P. Bartholomew and George Janssen. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention*, 242–5 (1930).—The min. amt. of K which it is necessary to maintain in soln. to produce optimum growth varies with different plants. Alfalfa and Hubam clover required a min. K concn. approximating 0.5 p. p. m., cow peas, oats, soy beans and cotton 2.0 p. p. m., and Sudan grass 3.0 p. p. m. In all expts. good growth was made from a concn. of only 0.5 p. p. m. Plants have the ability of absorbing relatively large amts. of K very rapidly, and the amt. absorbed depends upon the amt. in soln. and not upon the needs of the plant, large amts. being taken up when no visible growth is being made. The plant quickly adjusts itself to changes in the concn. of K. Although plants absorb K very rapidly symptoms of K starvation in the later stages of growth are infrequent because the plant is able to transfer the K from the older to the embryonic regions and re-utilize it for growth processes. K. D. Jacob

Isotopes of potassium: their association with plant life. J. G. F. Druce. *Chem. News* **142**, 33–5(1931); cf. *C. A.* **24**, 1885.—Addnl. exptl. work confirms D.'s earlier statement that KCl from the ashes of potato stalks contains more K^{41} than is present in ordinary KCl. In non-living plant tissue there is no accumulation of the higher isotope. Louise Kelley

Spike disease of Dodonaea viscosa. B. N. Sastri and N. Narayana. *J. Indian Inst. Sci.* **13A**, 147–52(1930); cf. *C. A.* **25**, 315.—Diseased tissues of *Dodonaea viscosa*, as compared with healthy tissues, showed a higher nitrate, nitrite, NH_3 and amide content, a tendency toward accumulation of sugar and starch, a higher diastatic activity and a deficiency in Ca. *Zyzyphus oenoplia*, which suffers from a similar disease, also shows Ca deficiency. Louise Kelley

Proteins of Indian foodstuffs. III. Globulins of Bengal gram (Cicer arietinum, Linn.) and horse gram (Dolichos biflorus). Nuggihalli Narayana. *J. Indian Inst. Sci.* **13A**, 153–8(1930); cf. *C. A.* **23**, 211.—A knowledge of the compn. of Bengal gram and horse gram is important because of the relation of these pulses to human and animal nutrition, resp. The globulins in these grams were isolated and were found to

contain sufficient quantities of arginine, tyrosine and lysine, but to be deficient in cystine and tryptophan. The arginine content of the Bengal gram was much higher than that usually found in globulins of other Indian pulses. LOUISE KELLEY

Physiological studies on Drosera. II. The effect of quinine and atoxyl on pepsin. KUNIO OKAHARA. *Science Repts. Tôhoku Imp. Univ.* [4], 5, 739–55(1930); cf. *C. A.* 25, 983.—In the course of studies made by O. to det. whether *Drosera* enzyme and pepsin are identical, he detd. the effect of quinine-HCl and atoxyl on pepsin. Digestion expts. were carried out at 39°, and the extent of digestion was detd. by the nephelometric method; a 40% soln. of sulfosalicylic acid was used to cause turbidity. Variations in the method of mixing the solns. and in the concn. of the solns. of poison used caused the digestion to be accelerated, repressed or unchanged. LOUISE KELLEY

Composition and properties of certain red and yellow plant pigments. LEONORA N. BILGER. *Bull. Basic Sci. Research* 3, 37–46(1931).—The pigment (I) extd. from Japan red peppers is shown to differ in chem. compn. from *lycopin* and the pigment from paprika. Ultimate analyses for I gave C 74.69 and 74.69%, H 9.95 and 10.26%, O (by difference) 15.36 and 15.05%. The crystals were deep red, m. p. 167–9° (when taken immediately after purification), 120–1° (after slight fading) and 50–60° (after complete fading); they were moderately sol. in EtOH and MeOH, sol. in C_6H_6 and ether, easily sol. in $CHCl_3$ and CS_2, nearly insol. in petroleum ether and insol. in water. They were purified by pptn. from ether by adding petroleum ether and chilling and by recrystn. from CS_2. I shows no rotation. The dry crystals of *lycopin*, *carotene* (II), *capsanthin* and I are readily bleached when exposed to air and light. Alc. solns. of I and II may be kept in stoppered glass test tubes (air present) for weeks in daylight at room temp. without noticeable fading and for months in a refrigerator. Alc. and $CHCl_3$ solns. of I and II were exposed in water-cooled quartz tubes to ultra-violet light and in cellophane cover cells to soft x-rays with and without air present. In general, alc. and $CHCl_3$ solns. faded much more rapidly than CS_2 solns. In the presence of air, alc. and $CHCl_3$ solns. completely lost their colors after 3 hrs.' exposures to ultra-violet light. CS_2 solns. required 9 hrs. for complete fading or 26 hrs., when air was excluded. In all cases of exposure to ultra-violet light, a very small amt. of a brown resinous material formed on the walls of the tubes. When the filtered solns. were evapd. to small vols. and cooled, sparkling colorless crystals sepd. Fading of the pigment was also brought about with soft x-rays but in a much shorter time than with ultra-violet light. After irradiation with ultra-violet light neither I nor II showed bands in the visible region; I but not II showed bands in the ultra-violet. Twenty-five photographs of absorption spectra of these pigments are appended. J. A. KENNEDY

Preliminary study upon the nucleo-cytoplasmic ratio in plant tissues. F. E. HEULIN. *Australian J. Expll. Biol. Med. Sci.* 6, 59–64(1929).—The ratio: nucleic acid N/(coagulable protein N-nucleic acid N) found for wheat plants 29, 46 and 57 days old was 0.0341, 0.0124 and 0.0040, resp. C. G. KING

Variability of rice varieties in resistance to toxic action of potassium chlorate and its practical significance. MORIMASA YAMASAKI. *J. Imp. Agr. Expt. Sta.* (Japan) 1, 1–22(1929).—Rice seedlings grown in tubes of $KClO_3$ soln. (0.005–2.0%) were found to vary in susceptibility to toxic action. Upland rice was more resistant than lowland varieties, and among strains of upland rice, a direct correlation between drouth resistance and resistance to toxicity was shown. In all varieties there was a similar relation between length of growing season and resistance. Injury from $KClO_3$ was shown by a dark-brown discoloration of the leaf veins. Conditions of growth previous to placing seedlings in $KClO_3$ soln. also affected resistance; those grown under upland conditions and exposed to the sun were less resistant than those previously grown in a watered nursery and shaded. Resistance to toxicity decreased with the age of the seedlings. Differences in resistance to toxicity are attributed to varietal differences in permeability of root cells, not to differences in osmotic pressure of cell sap. K. KITSUTA

Variation and correlation among varieties of wheat and barley in regard to resistance to the toxic action of potassium chlorate. MORIMASA YAMASAKI. *J. Imp. Agr. Expt. Sta.* 2, 139–62(1929).—See *C. A.* 24, 4576. K. KITSUTA

Variations in the unsaponifiable lipides and in the lipide phosphorus of Sterigmatocystis nigra as a function of the mineral composition of the liquid culture medium. CHARLES PONTILLON. *Compt. rend.* 191, 1367–9(1930).—The mineral compn. of the nutritive medium has a considerable influence upon the lipide metabolism of *Sterigmatocystis nigra*. B. S. LEVINE

Frangularoside, a new rhamnoside of the freshly dried bark of black alder. M. BRIDEL AND C. CHARAUX. *Compt. rend.* 191, 1374–6(1930); cf. *C. A.* 25, 984.—A

method for the prepn. and purification of the rhamnoside is given and its properties are described. The use of freshly dried bark is essential. B. S. LEVINE

The distribution of nitrogen in plant extracts that contain a high proportion of nitrate nitrogen. ALBERT C. CHIBNALL AND E. J. MILLER. *J. Biol. Chem.* 90, 189–96 (1931).—Exts. of plant products which contain a high percentage of nitrate N show certain abnormalities in the distribution of N, and it has been necessary to revise the methods employed for the partition of the N into the now commonly accepted groupings. Reduction of nitrate was found to occur during HCl hydrolysis (cf. Vickery and Pucher, *C. A.* 25, 1552–3); this reduction was promoted by the presence in the ext. of an easily oxidizable substance which apparently was nitrogenous in character. A particular sample of rye grass (*Lolium perenne*) was found to contain 12.7% of its total N as nitrate N, an amt. equal to 4.4% of the dry wt. of the leaf. Only the tobacco leaf has previously been shown to contain such a relatively enormous amt. of nitrate.
A. P. LOTHROP

The fermentable principle of the tubers of the asphodel. II. C. NEYRON. *Bull. sci. pharmacol.* 38, 38–51(1931); cf. *C. A.* 25, 1274.—The rhizomes and tubers contain the glucoside *asphodeloholoside* which was obtained as a $Ba(OH)_2$ compd. sol. in water and pptd. by dil. EtOH. It is partly decomposed by CO_2. The glucoside itself cannot be crystd.; it is extremely sol. in water and EtOH. The mol. wt. is about 700; the rotatory value is between —18° and —19°. After hydrolysis, the rotation is —67°; the sugars formed are levulose and an aldose, probably glucose. It is easily fermented, especially by *Aspergillus niger*, and only partly by sucrase. A. E. MEYER

Presence of methyl mercaptan in the leaves of Lasianthus laevigatus Bl., L. lucidus Bl., L. purpureus Bl., L. stercorarius Bl., and L. bracteolatus Miq. D. R. KOOLHAAS. *Biochem. Z.* 230, 446–50(1931).—A method is discussed for the detn. of MeSH in the steam distillate from leaves. S. MORGULIS

Chemistry of citric acid formation by molds. IV. Transformation of saccharic acid. K. BERNHAUER, H. SIEBENÄUGER AND H. TSCHINKEL. *Biochem. Z.* 230, 466–74(1931); cf. *C. A.* 23, 1151.—Expts. with 26 strains of mold fail to give any evidence for the formation of saccharic acid from glucose or gluconic acid, or for the formation of citric acid from saccharic acid or its salts. There is thus no evidence that saccharic acid is an intermediate product in citric acid formation. A no. of the molds transformed saccharic acid to oxalic acid. S. MORGULIS

Characterization of Aspergillus niger strains. III. Further propagation experiments and comparison of different mold strains. K. BERNHAUER, F. DUDA AND H. SIEBENÄUGER. *Biochem. Z.* 230, 475–83(1931); cf. *C. A.* 23, 2741.—The different strains are differentiated by their ability to produce citric acid and to form gluconic acid.
S. MORGULIS

Isotopes and living organisms. V. I. VERNADSKII. *Compt. rend.* 192, 131–3 (1931).—The work of Loring and Druce (*C. A.* 24, 1885) indicates that K extd. from the potato has an at. wt. of 40.4–40.59 and is more radioactive than the lower isotope of K. These results are contested by Lowry (*C. A.* 25, 314) who extd. the K of cotton and of wheat and obtained an at. wt. of 39.09–39.31. V. prepd. compds. of K, Fe, Mg, Zn, Ca, Si and S from living organisms with a view to det. the at. wt. of each element. These data would throw some light on the hypothesis that living organisms sep. the isotopes of elements. This hypothesis is supported by the fact that N, C, H and other elements occur in living organisms in isotopic mixts., and that certain elements (such as Ca, K, Fe and Mg) present in the vital cycle tend to remain there. N. M. NAYLOR

The liberation of iodine from the gland cells of Bonnemaisonia asparagoides by the action of ultra-violet light. ROBERT LAMI. *Compt. rend.* 191, 863–5(1930).—Irradiation of *Bonnemaisonia asparagoides* with ultra-violet light causes the liberation of I_2. It is possible that the algae are killed, and that the liberation of acids from the diffuse vacuoles causes this effect, but it is probable that it is a direct effect of the radiation which ionizes the free I_2 present in the gland cells. T. H. RIDER

Studies on the nature of rust resistance in wheat. V. Physiology of the host. W. F. HANNA. *Can. J. Research* 4, 134–47(1931).—Detns. were made of catalase, diastase and oxidase activity; rate of respiration; and content o fchlorophyll, xanthophyll and carotene in the leaves of 8 wheat varieties. With respect to their reactions to stem rust, these wheats vary from almost complete susceptibility in certain varieties to a high degree of resistance in others. Catalase activity increased as the plants approached maturity, whereas diastatic activity decreased with increasing age. No significant differences were found in the oxidase activity or respiratory rate of the varieties. Little Club and the varieties of the vulgare group proved to be relatively rich in chlorophyll and the carotenoids. It is suggested that photosynthetic processes may

take place more rapidly in the cells of the varieties having a high content of these pigments, and thus furnish conditions suitable for the growth of the rust mycelium.

J. W. SHIPLEY

The mechanism of growth in the cotton hair. F. T. PEIRCE. *Trans. Faraday Soc.* **26**, 809–13(1930); cf. *C. A.* **23**, 5381.—The deposition of sol. carbohydrate as cellulose involves linkages in 3 directions, each one corresponding to a stage in the physiology of the plant. The theory of orientation of glucose residues in the cell wall is developed. K. V. THIMANN

Useful device for evaporating alcohol from plant extracts. F. E. GARDNER. *Plant Physiology* **5**, 617–9(1930).—The device is attached to a Soxhlet extn. battery. It consists of an air pump driven by a $^1/_6$ h.-p. motor and connected to a piece of 0.75-in. iron water pipe 8 ft. long into which are fitted, at the proper intervals, 12 curved pieces of $^3/_{16}$-in. Cu tubing about 7 in. long, which lead into the necks of the flasks. The time necessary for the evapn. of 100 cc. 95% alc. is 15–20 min. and for 80% alc. considerably less than 1 hr. A diagram of the app. is given. WALTER THOMAS

Some organic acids of wheat plants. E. K. NELSON AND HEINRICH HASSELBRING. *J. Am. Chem. Soc.* **53**, 1040–3(1931).—In an investigation of the org. acids in growing wheat plants the aq. ext. was found to contain (% calcd. on the basis of green plants): malonic, by fractionation of esters, 0.005; aconitic, by Et_2O extn. of acids, 0.040; malic, by fractionation of esters, 0.056, by polarization, 0.064; citric, by fractionation of esters, 0.016, by pentabromoacetone, 0.019; oxalic, trace. The residue after water extn. contained 0.02% oxalic acid (0.11% on dry basis). C. J. WEST

Influence of neutral red on yeast respiration. MAX GEIGER-HUBER. *Proc. Acad. Sci. Amsterdam* **33**, 1059–68(1930).—Manometric measurements of the O_2 consumption at 20° showed that the respiration of bakers' yeast is independent of the p_H between 5 and 8.1. When neutral red is added 1:10,000, respiration in acid medium quickly rises 20–30% and aften an hour falls to 80% of the original. In alk. media it falls immediately. The older the cells, the more pronounced are these changes.

J. J. WILLAMAN

Changes occurring in stored alcohol plant extracts. JAMES E. WEBSTER. *Science* **73**, 77–8(1931).—Plant samples preserved in 80% EtOH + excess $CaCO_3$ were found to have p_H values of 4.6–6.0 and titers of 3–8. Celery exts. in 80% EtOH for 9 months doubled their NH_3 content at p_H 4.2 and quadrupled it at p_H 8+. There was always increase in NH_3 in exts. of grapes, celery, lettuce and spinach. W. urges that this method of preservation be studied by other investigations. J. J. WILLAMAN

Changes in the composition of oranges during ripening. P. R. v. d. R. COPEMAN. *Trans. Roy. Soc. S. Africa* **19**, 107–67(1931).—The growth and compn. of oranges were followed for 104 days; fruits from both unsprayed trees and from those sprayed with Pb arsenate were used. Most of the factors studied fitted rather well this modified form of equation for autocatalytic reactions: $\log (x - c)/(a - x) = K(t - t_1)$, where c is the value of the factor at the beginning, a is the final value, $K = k(a - c)$ (k is the velocity constant of the change) and t_1 is the time at which x has a value of $a + c/2$. The factors studied were wt. of fruit, skin and pulp, alc.-insol. residue, sol. solids, acidity, sucrose, glucose, fructose, ash, N, P, K, Ca, Mg, Fe. The proportion of P, both in the juice and in the ash, decreased during the period of ripening, and storage of P must occur in the early stages of formation of the fruit. The K content of the juice and of the ash increased during ripening, and the relatively large proportion of K in the mineral constituents of the juice indicates clearly the importance of this factor in the development of the fruit. The results indicate that the growth of the fruit is dependent upon a continual supply of K. It would appear that K is closely connected with the formation of carbohydrates in the plant, and it is believed that this factor is also assocd. with the transference of the carbohydrates. The K content of the juice of the sprayed oranges is greater than that of the unsprayed oranges, and the proportion of sugar in the total solids was also higher in this case. The Ca and Fe contents of the juice decreased during ripening, while there was no significant rate of change in the content of Mg and no significant increase in N or in ash contents in the juice. Ca appears to resemble P in that it must be stored in the early stages of development of the fruit. P–N ratios in the case of both sprayed and unsprayed oranges are similar and show no significant difference, the mean values being 0.352 and 0.351, resp. The value of the ratio decreased in both series during ripening. On the other hand, the K–N ratio was slightly higher in the case of the sprayed oranges, the mean values for the 2 series being 1.83 and 1.67, resp. The value of this ratio remained more or less const. during ripening. During this period the wt. of the orange increased, and this was accompanied by an increase in the wt. of pulp, in the amt. of sol. solids and sugars in the juice and in the amts. of these constituents per fruit.

At the same time the proportion of cell-wall material in the pulp and of the acid in the juice decreased. During the final stages of growth transpiration became dominant, with the result that the fruit lost wt. because of loss of water. At the same time there was a corresponding increase in the concn. of sol. solids in the juice. The acidity of the sprayed oranges was less than in the unsprayed oranges, while there was a greater content of cell-wall material in the sprayed oranges. At the same time there was a slightly higher content of sugars in the juice of the sprayed oranges, and this appears to be due to the fact that the amt. of sucrose was increased. The rates of change of the various factors were not affected by the spraying, and it was concluded that the arsenate spray exerts an internal physiol. action on the trees, with the result that there is a selective oxidation of the respiratory materials in the fruit. As a consequence of this action the acid in the sprayed oranges forms a more important source of respiratory material than the cell-wall material. The action must be caused by the absorption of arsenical compounds through the leaves of the trees. The solution of the problem depends upon the use of sprays other than arsenical. A bibliography is included. J. J. WILLAMAN

E—NUTRITION

PHILIP B. HAWK

Changes in the composition of blood in rabbits fed on raw and cooked soy beans. ERNEST TSO AND S. M. LING. *Proc. Soc. Exptl. Biol. Med.* **28**, 219–20(1930).—The feeding of raw or cooked soy beans or a diet of millet and cabbage had no effect on the concns. of uric acid, urea N and inorg. P in the blood of the rabbit. The blood cholesterol value was slightly higher on the soy-bean diets. Uric acid was detd. by the Folin improved method (cf. *C. A.* **24**, 2771). Twice the vol. of blood filtrate was used and the standard was reduced to 2 cc. C. V. BAILEY

Effects of a hyperprotein and hyperpurine diet (pancreas) on the rat. P. RONDONI. *Arch. ist. biochim. ital.* **2**, 243–68(1930).—On a diet of pancreas, either alone or mixed with flour, rats lose wt., especially in the former case, while the kidney wt. increases both absolutely and relatively. Other effects of such diet include: slight tendency to leucocytosis; diffuse phenomena of swelling in the parenchymal organs; more marked vital colorability with trypan blue; an acidotic condition; increased thermal reactivity compared with that caused by subcutaneous injection of peptone or suspension of uric acid; increased disposition to inflammation. B. C. A.

Ergosterol and antirachitic vitamin. M. COMEL. *Arch. ist. biochim. ital.* **2**, 281-306(1930).—When administered in excessive doses, irradiated ergosterol maintains its efficacy as a Ca-fixing and antirachitic remedy but gives rise to toxic phenomena. The toxicity is displayed mainly by pptn. of lime in the viscera and by a characteristic atrophy of their cellular elements, and is probably due to the ergosterol itself rather than to admixed substances. This toxicity throws doubt on the identity of irradiated ergosterol with the lime-fixing vitamin, but the irradiated ergosterol may represent the active constituent of the vitamin, the latter being formed by union of the ergosterol with a protective lipin. B. C. A.

Effect of x-rays on ergosterol. M. SUMI. *Bull. Inst. Phys. Chem. Research* (Tokyo) **8**, 640–4(1929).—Vitamin D, formed by irradiation of ergosterol with ultraviolet light, is destroyed by 4 hrs.' exposure to x-rays. The spectrum of ergosterol and activated ergosterol extends further into the ultra-violet region after irradiation with x-rays. B. C. A.

Biological investigations with milk changed by the removal of fats and the addition of carbohydrates. L. RANDOIN AND R. LECOQ. *Compt. rend. soc. biol.* **102**, 528–31 (1929); cf. *C. A.* **25**, 729.—Pigeons were fed daily with a mixt. prepd. from 8 g. of agar agar, 2 g. of filter paper and 90 g. of dried milk or dried milk from which fats had been removed. The animals fed on the fat-free diet died in 30–50 days. In another series, the diet consisted of 50 g. of dried milk (fat-free or normal), 40 g. of carbohydrate and 10 g. of roughage. With the fat-free diet, the animals fed with lactose, sucrose, maltose, dextrose and dextrin died in 15–25, 50–70, 70–100 days, 3–4 months and not less than 5 months, resp. With the normal milk diet, only the animals fed with lactose died (50–80 days). B. C. A.

Dependence of the sugar curves of the blood on acid and alkaline diets with subcutaneous injection of pilocarpine. E. T. MINKIR-BOGDANOVA. *Russian J. Physiol.* **13**, 151–6(1930).—An acid or an alk. diet influences the sugar of the blood but little, the sugar content and its max. and min. values being approx. the same in the 2 cases. With either diet, subcutaneous injection of pilocarpine produces neither a definite increase nor

a definite lowering of the sugar content of the blood, but the divergences from the mean value are more marked than those of most of the control expts. B. C. A.

Variations of the catalase curve of blood after introduction of pilocarpine on an acid or alkaline diet. S. A. POVORINSKAYA. *Russ. J. Physiol.* **13**, 188–92(1930).—The curves representing the catalase content of the blood at various times after subcutaneous injection of pilocarpine are of a uniform type for children receiving an alk. but not an acidic diet; where a mixed diet is taken, the curves are of a mixed type. The catalase-time curves for children on an alk. diet not receiving pilocarpine are not of a uniform type. The catalase curves vary irregularly for the same individual according to the day and hour at which the blood is taken. No parallelism is found between blood catalase and hemoglobin contents. B. C. A.

Variations in the chloride and water contents of striated muscle, liver and kidney during acute experimental scurvy. LUCIE RANDOIN AND ANDRÉE MICHAUX. *Compt. rend.* **192**, 108–10(1931); cf. *C. A.* **24**, 4535; **25**, 1559.—In guinea pigs deprived of the antiscorbutic vitamin the Cl and water contents of the liver and kidney increase only slightly above normal, but the Cl content of the muscle increases considerably. This is not dependent upon the Cl content of the diet, as the same effect was noted in guinea pigs receiving diets contg. no NaCl, 0.5% NaCl and 1.5% NaCl. RACHEL BROWN

Observations and measurements on vitamin A. P. KARRER, B. EULER, H. VON EULER, H. HELLSTRÖM AND M. RYDBOM. *Arkiv. Kemi, Mineral. Geol.* **10B**, No. 12, 6 pp.—A study is made of the metabolic variations of carotene and its relationship to vitamin A. Carotene was found to be concd. in the blood plasma or serum. Almost none was present in the red blood cells even in those bloods which contained large amts. of this pigment. In 50 samples of normal human blood sera the av. was 0.8 Lovibond units per 10 cc., although one value was 4.5 units. With herbivorous animals, much higher values were obtained. With ox serum the content was 17 units and with cow sera taken in Sept. the av. was 14 Lovibond units (11–16). A seasonal variation occurred in these animals, the highest concns. being obtained in the fall after a summer of fresh pasturage while much lower amts. were obtained after the usual winter feed. While it is admitted that carotene is not the growth-promoting factor identical with vitamin A, it is suggested that this latter factor may be a hydrogenated carotene which has been formed in the liver through the action of carotenase. A spectrometric study of these pigments in biostearin and in the distillates of cod-liver oil and shark-liver oil definitely proves that a growth-promoting factor independent from carotene exists. A very rapid deterioration of these substances occurs, as indicated by the rapid disappearance of the absorption bands. Ether-sol. substances having a different spectometric picture were obtained from germinating barley and *Fucus vesiculosis*. H. J. D., JR.

The ether-soluble substances of polished rice. YOSHIKAZU SAHASHI. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 882–90 (Abstracts 84–5 (in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, No. 271–3(1930)).—A further substantiation of earlier expts. (*C. A.* **23**, 1937; **24**, 3264) in which it was demonstrated that polyneuritis in birds is not to be traced to toxic compds. in the alc.-sol. fraction of polished rice as claimed by Teru-Uchi (*C. A.* **24**, 1146). The ether-sol. portion consists of palmitic, oleic and linoleic acids, phytosterol and other oily nonsaponifiable matter. The injection of this ext. was not followed by any toxic symptoms in pigeons or in mice, nor was any difference noted in the effect of feeding alc.-extd. polished rice or that washed only with water. In either case the diet must be supplemented with vitamin B to prevent the onset of polyneuritis. H. J. DEUEL, JR.

The vitamin content of marine plankton. J. C. DRUMMOND AND E. R. GUNTHER. *Nature* **126**, 398(1930).—Phytoplankton gave a pos. test for vitamin A in 20 mg. doses and the $SbCl_3$ and absorption spectrum tests were likewise pos. These were neg. for zoöplankton. The line test for vitamin D was only doubtfully pos. with phytoplankton but unmistakably pos. with zoöplankton, while the x-ray gave neg. results with both species. H. J. DEUEL, JR

The relation of vitamins to carcinogenesis. WARO NAKAHARA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, 32–6(1930); *Chem. News* **142**, 86–7(1931).—In opposition to Fujimaki, Kimura, Wada and Shimada (cf. *C. A.* **21**, 1836), N. finds no direct relationship between vitamin-A deficiency and cancer in rats. Overdosage with vitamin D was likewise ineffective in producing this condition. H. J. DEUEL, JR.

Problems of nomenclature and dosage in experiments with Vigantol. M. SCHMIDTMANN. *Klin. Wochschr.* **9**, 1629–30(1930). H. EAGLE

The use of an acid diet in the treatment of bronchial asthma. KURT TEIFENSEE *Klin. Wochschr.* **9**, 1675–8(1930); cf. *C. A.* **24**, 2798.—Untreated cases of bronchial asthma show a decreased excretion of acid and NH_3 during an attack. An acid diet,

with addn. of NH_4Cl, $NH_4H_2PO_4$ and "Silicalcium," leads to a significant improvement in the asthmatic condition. Asthmatics kept in a secluded room show an increased excretion of acid and a decreased no. of attacks. Definite improvement, however, was obtained only when an acid diet was given. Alkalosis is therefore an important symptom in bronchial asthma, the correction of which affects the whole clinical picture. H. EAGLE

A new principle in the biological demonstration of irradiated ergosterol. JOSEF WARKANY. *Klin. Wochschr.* 9, 2152–3(1930).—Rabbits which usually excrete no phosphate, and are given 30–100 mg. of irradiated ergosterol in their food, show large quantities of phosphate in the urine in 48 hrs. A normal phosphate excretion can be prevented by daily $CaCO_3$ in the food. H. EAGLE

The fate of oxidizing enzymes in foods in the human digestive canal. I. BOAS. *Klin. Wochschr.* 9, 2295–6(1930).—Using bananas (which are particularly rich in catalase, oxidase and peroxidase) as a test meal, B. finds that all 3 are inactivated if the stomach is acid (to Congo red), but that this inactivation is reversible, the enzymes being reactivated by the neutralization of the mixt. Oxidase is the most sensitive to acid. As shown by the passage of a duodenal sound, as well as by expts. on a dog with fistula of the ileum, the enzymes are reactivated when the food reaches the intestines. Normal feces contain no oxidase. If pus is present, oxidase may appear; if blood is present, peroxidase may appear. Catalase is normally present. Normal urine contains no peroxidase or catalase, but they may appear in pathol. conditions. Oxidase may be present, but it is thermostable and is probably a metallic catalyst. H. EAGLE

The active principle of liver in pernicious anemia. KURT G. STERN. *Klin. Wochschr.* 10, 172–5(1931).—A summary of the recent work. H. EAGLE

The chemical nature of vitamin D. ETSUO TAKAMIYA. *J. Dept. Agr. Kyushu Imp. Univ.* 3, 1–27(1930).—A repetition and extension of studies previously reported (cf. *C. A.* 24, 3523; 25, 123, 536). New work includes a comparison between the action of O_3 and of ultra-violet light upon cholesterol and olive oil with respect to photoactivity, color reactions, and m. p. of the cholesterol. The behavior of the ozonized materials was similar to that of those exposed to ultra-violet light. Ozonized ergosterol was found to be antirachitic when fed to rats made rachitic on McCollum's diet 3143, the potency rising to a max. and then falling off with increasing time of exposure to O_3. The relationship of these exptl. results to the chem. nature of vitamin D is discussed, and it is tentatively concluded that the antirachitic portion of the ionized ergosterol is ergosterol monoozonide Δ_1, which is possibly identical with vitamin D. S. B. FOSTER

Influence of radium emanation on the transformation of ergosterol to vitamin D. J. MAISIN, W. MUND, Y. POURBAIX AND A. CASTILLE. *Compt. rend. soc. biol.* 103, 534–6(1930); *Physiol. Abstracts* 15, 258.—Ergosterol in soln. in paraffin irradiated by Ra rays in a closed receptacle undergoes a definite chem. transformation. The product obtained is endowed with antirachitic properties. G. G.

Reducing power of tissues in animals with low cystine diet. N. C. LACLAU AND A. D. MARENZI. *Rev. soc. argentina biol.* 5, 768–73(1929); *Physiol. Abstracts* 15, 233.—The reducing power is less than in the controls. Differences are greater in liver than in muscle. There is a certain relation between reducing power and glutathione content of tissues. G. G.

Experimental production of bladder stones. S. PERLMANN AND W. WEBER. *Münch. med. Wochschr.* 77, 680–1(1930); *Bull. Hyg.* 5, 699.—Twenty-three % of the rats fed on a vitamin A-deficient diet had phosphatic stones in the bladder. Of 100 rats fed on an unsuitable but not deficient diet, half died in 3 months; of the remaining 50, 7 showed gravel at the end of 80 days. The small stones consisted of urates and resembled those of human beings. All normally fed rats were free from stones. Vitamin-A deficiency is not the only factor, but it is an important one. Europeans have a predominance of urate stones, while oxalate stones predominate among the Japanese. In the case of children, stones are probably due to improper feeding, but in adults anatomical factors, infection and disordered metabolism are the probable causes. GEORGE R. GREENBANK

The nutritive value of soy-bean cake and purified soy-bean cake. SAJIRO OHTOMO. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 10–2.—Feeding and artificial digestion expts. show that the alc.-extd. cake is less nutritive. V. F. H.

The occurrence of vitamins A and B in soy-bean oil and cake. SAJIRO OHTOMO. *Abstracts from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 13–5.—Rat and pigeon feeding expts. indicate that soy-bean cake and oil contain some vitamin A. This is contrary to McCollum, *et al.* (*C. A.* 10, 2902). V. F. HARRINGTON

Studies on experimental rickets. III. The isolation of ergosterol from brewer's

yeast and the activation of ergosterol by ultra-violet light. SEIICHI IZUME, YOSHINORI YOSHIMARU AND ISAO KONATSUBARA. *Abstract from Rept. Central Lab. S. Manchuria Railway Co.* 1929, 18–21.—The ergosterol, m. 160–1° and having $[\alpha]_D^{25} = -122°$ in $CHCl_3$, after irradiation cured rickets in doses of 0.001 mg. per day. Rays of 311–260 $\mu\mu$ are most effective in imparting antirachitic power. Too long exposure destroys this power. V. F. HARRINGTON

Recent developments in vitamin research. W. D. SALMON. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention*, 288–92(1930).—In general, diets in the South are rather low in vitamins A and C and dangerously low in what for the present may be called the vitamin-G fraction, including the pellagra-preventive factor. They are also deficient in Ca and in vitamin D. There is little doubt that an abundance of sunlight is the only thing that prevents rickets from being more prevalent in this region. K. D. JACOB

Dietary standards for pregnancy. CALLIE COONS. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention*, 293–5(1930).—A study was made of the retention of N, Ca and P by 9 pregnant women at different stages of fetal development. There was a distinct tendency for N retention to increase with an increase in intake and *vice versa*, and N was stored much in excess of the probable fetal demand. Storage of Ca was highest in late pregnancy, as was also the curve of probable fetal demand for Ca. Only 3 of the 9 women were storing as much Ca as the probable fetal demand, and many were storing much less. Assocd. with low Ca retention were instances of maternal tooth destruction and of poor bone formation as shown by x-ray examn. of the 8-day old baby. Retention of P was even more const. than intakes, the same woman storing as much in the middle months as in late pregnancy. Also the rate of storage was well above the fetal demand in the middle months. K. D. JACOB

Antirachitic activation of ergosterol by soft x-rays. ELIZABETH SHELOW AND JOHN R. LOOFBOUROW. *Bull. Basic Sci. Research* 3, 47–64(1931).—Theoretical considerations show that any radiation of shorter wave length than about 3000 or 3100 A. U. should be capable of activating ergosterol. This applies to radiations throughout the x-ray and γ-ray regions. The extent of activation should not be appreciable, however, except in portions of the spectrum in which the absorption is of consequence. Calcns. show that the greatest x-ray absorption of ergosterol lies in the extreme soft x-ray region and that appreciable activation should be expected in or near this region. Irradiation expts. with soft x-rays are described, and absorption spectra and animal expts. indicative of the activation of ergosterol by soft x-rays are recorded. The effect of x-rays on the solvent might be more pronounced than on ergosterol or cholesterol with solvents contg. elements of higher at. wt. than H, C or O; and consideration must be given to the possibility of glass containers giving fluorescent ultra-violet radiations in the presence of x-rays. The effect of soft x-rays in activating ergosterol may be a primary or secondary one. The literature is reviewed and photographs and x-ray pictures are given. J. A. KENNEDY

Modern problems of nutrition. AUGUSTIN D. MARENZI. *Ann. farm. bioquim. Suplemento* 2, 1–35(1931).—A comprehensive review of the subject along the following lines: I. Complete diets. Factors of importance: equilibria (*a*) caloric, (*b*) N, (*c*) mineral, (*d*) vitamin. II. The importance of the nitrogenous substances: (*a*) protein minimum, (*b*) practical protein minimum, (*c*) high- *vs.* low-protein diets. III. The nutritive value of proteins. Supplemental value. Its relation to the amino acid content. (*a*) Methods for the detn. of nutritive values of a substance, (*b*) the nutritive value of proteins from the viewpoint of maintenance and (*c*) of growth, (*d*) supplemental value of proteins, (*e*) the relation between biol. value of proteins and their chem. constitution. IV. The relation between amino acids and maintenance, and the growth of animals. Methods of study. General results. Conclusions. There is no bibliography. B. S. LEVINE

Antioxidants and the autoxidation of fats. H. A. MATILL. *J. Biol. Chem.* 90, 141–51(1931).—To secure information on the chem. nature of the antioxygenic substances that are found in natural oils and that prevent autoxidative destruction of fat-sol. vitamins, a series of hydroxy aromatic compds. was tested for their capacity, when used in a quantity of 0.02%, to prolong the thermal oxidation induction period of a standard mixt. of lard and cod-liver oil. The antioxygenic capacity of phenols resides in 2 OH groups in the *o*- or *p*-configuration; when these are in the *m*- position the compd. is inactive. The OH groups are ineffective unless attached directly to the ring; fully hydroxylated inositol is ineffective. In the naphthols 1 OH group is sufficient, and, in keeping with its accepted behavior, α-naphthol has the character of an *o*-compd. and is

much more effective, as an antioxidant, than β-naphthol; quinone is effective and β-naphthoquinone is even more so, but the α-form is entirely inactive. A no. of sterols of animal origin and sitosterol from wheat, corn and lettuce were all inactive. The existence of pro- and anti-oxygenic substances among the unsaponifiable constituents of natural fats and oils suggests that some of these may be concerned with the physiol. action of the fat-sol. vitamins and methods for their segregation from the sterols are under investigation. It is suggested that in the prepn. and manipulation of easily autoxidizable substances, the presence of traces of antioxidant will prevent undesirable oxidative changes. A bibliography of 42 references is given. A. P. LOTHROP

The effect of nitrous acid upon the components of the vitamin-B complex. H. C. SHERMAN AND M. L. WHITSITT. *J. Biol. Chem.* 90, 153–60(1931).—The "protein-free" milk prepn. of Osborne and Mendel was used as a suitable material contg. both vitamins B (B_1) and G (B_2). The solns. were treated with HNO_2 in 2 ways: in one the gas was drawn by aspiration into the vitamin soln. and in the other the HNO_2 was generated directly in the vitamin soln. by adding $NaNO_2$ to it and dropping in an equiv. amt. of 1:1 HCl. After 14 hrs. in each case the dissolved gases were removed under reduced pressure and the liquid was then neutralized with 0.2 *M* NaOH. Treatment by the aspiration method had little, if any, influence upon vitamin B but a large diminution of potency occurred when the HNO_2 was generated in the soln. These results suggest that vitamin B may be a nitrogenous base but of such a structure as to be more resistant to HNO_2 than are typical primary amines. No destruction of vitamin G was brought about by aspiration of HNO_2 through the soln., but partial destruction by the 2nd method was indicated by feeding tests when the data were taken for an 8-week but not for a 4-week exptl. period. It seems probable from these expts. and other unpublished observations that vitamin G_1 (B_2) is stable toward HNO_2 but that there is more or less destruction of one of the newer and not yet clearly defined factors making up the vitamin-G complex and that the reaction involved is likely one of oxidation rather than deaminization. A. P. LOTHROP

Studies on alimentation and nutrition. IV. Means and measures of food economy. C. FOA. *Arch. sci. biol.* (Italy) 15, 445–94(1930).—This is a review and is part of a series of investigations promoted by the Italian National Research Council. The subjects discussed are bread, distribution of food resources between man and domestic animals, utilization of leaves, utilization of waste and residues from slaughter houses, refrigeration and food preservation, utilization of refuse as fertilizer, savings in kitchen and table practice and methods for evaluating the food requirements of man. PETER MASUCCI

The chemistry of nutrition. FILIPPO BOTTAZZI. *Atti III congresso naz. chim. pura applicata* 1930, 51–64.—The latest developments in the biochemistry of carbohydrates, proteins, enzymes and vitamins are reviewed and discussed. The study of metabolism by thermodynamic methods alone is considered insufficient. A detailed knowledge concerning the chemistry of nutritive substances is essential, in addn. to knowing their energy content, before the biol. value of the substances can be ascertained. PETER MASUCCI

The phosphate esterification and the phosphatase action in B-avitaminosis. J. BODNÁR AND ANTON KARELL. *Biochem Z.* 230, 233–7(1931).—The muscles and livers of pigeons suffering from vitamin B deficiency esterify H_3PO_4 77 and 146%, resp., more than the organs from healthy birds. No difference was found between the normal and vitamin B deficient pigeons so far as the phosphatase activity of the muscles and livers is concerned. S. MORGULIS

Intermediate carbohydrate metabolism. VI. Sugar assimilation, phosphorus and water metabolism during prolonged intravenous injections of glucose, fructose and galactose. M. WIERZUCHOWSKI, W. PIESKOW AND E. OWSIANY. *Biochem. Z.* 230, 146–72(1931); cf. *C. A.* 22, 3232.—The total reduction of deproteinized blood from 3 well-nourished dogs, in fasting condition, ranged between 91 and 104 mg. %, of which 54–67 mg. % was due to glucose and 34–40 mg. % was due to residual reduction. In the continuous intravenous injection of glucose for 3 hrs. at the rate of 2 g. per hr. the blood sugar during the first hr. rose on the av. of 300 mg. % but fell during the next 2 hrs. This diphasic reaction was not observed in the other hexoses. Two hrs. after the injection the blood sugar was lowered below the initial level. During the expt. 10.5% of the injected glucose was eliminated in the urine, the glucosuria curve like the glucemia curve being also diphasic. The rest of the injected sugar was utilized. Two hrs. after the injection there was no more glucosuria. When fructose was injected, the fructose concn. of the blood rose gradually but was on the av. lower than the glucose concn. in parallel expts. However, of the total amt. of injected fructose 10.5% was lost in the

urine, the rest having been assimilated. Two hrs. after the injection the fructose disappeared from the blood, and only traces were found in the urine. With galactose injections the blood galactose concn. increased very rapidly, becoming 800 mg. % in the middle of the third hr., and not until 9 hrs. after the injection did the galactose disappear from the blood and urine. Only about 30% of the galactose was utilized, the rest being excreted in the urine. Under the influence of insulin the diphasic nature of the reaction after the injection of glucose disappeared, since the glucemia in the first hr. was much diminished and the assimilation definitely increased. The insulin had practically no effect on the fructosemia or on the utilization of fructose, but it did greatly stimulate the rate of removal of galactose from the blood and improved its assimilation to such an extent that only 42% was excreted in the urine. The injection of fructose or galactose of itself does not affect the glucose concn. of the blood, but under the influence of insulin the glucose concn. diminishes while the concn. of the fructose or galactose actually rises. The "residual reduction" remains unchanged when either glucose or fructose was injected. In these expts. no relation was found between the blood and urine P values. With a const. hexose injection the blood became most dild. with galactose and least dild. with fructose. The quantity of urine corresponded to the amt. of excreted hexose. **VII. Lactic acid production under the influence of prolonged intravenous injection of glucose, fructose and galactose.** M. Wierzuchowski and M. Laniewski. *Ibid* 173–86.—The lactic acid concn. of the blood of fasting dogs varied from 7 to 25 mg. %, the hourly excretion in the urine ranging from 1.4 to 5.1 mg. In expts. with a continuous intravenous injection for 3 hrs. at the rate of 2 g. per hr. the blood lactic acid curve for each hexose presented rather definite characteristics. The lactic acid excretion ran parallel to the changes in the blood concn. Most lactic acid was formed from fructose and occasionally from galactose, and least from glucose. After glucose injections about 0.1 g. lactic acid was excreted, after galactose injections 0.1–0.3 g. and after fructose injections 0.3–0.9 g. more than before the injections. With insulin the lactic acid excretion was increased with all 3 sugars. The lactic acid formation is responsible for the acidosis during the sugar injection, the rise in lactic acid concn. of the blood being more or less correlated with the increase in concn. of the hexose **VIII. Respiratory metabolism of intravenously injected glucose, fructose and galactose.** M. Wierzuchowski. *Ibid* 187–224.—During the expts. with continuous intravenous hexose injections the av. increase in the nonprotein R. Q. was for glucose 0.23 without insulin and 0.26 with insulin, for fructose 0.24 and 0.30, and for galactose 0.13 and 0.18, resp. The sp. dynamic action of the glucose was 9.7%, of fructose 13.8% and of galactose 17.3% of the caloric content of the assimilated part of the hexose. The greatest rise in heat occurred between the second and third hrs. and was 51% for glucose, 63% for fructose and 32% for galactose. In the expts. with insulin 2 periods were distinguished: hyperglucemic, while sugar and insulin were being injected, and hypoglucemic when nothing was being injected. In the first period the increase in heat production was for glucose 21%, fructose 38% and galactose 23% greater than in corresponding expts. without insulin. The greatest increase in heat was 57% for glucose, 85% for fructose and 32% for galactose. During the hypoglucemic period, 4–5 hrs. after the injection, the heat production was increased 36%. The largest amt. of sugar which the dogs were able to oxidize was 0.5 g. per kg., and of the total assimilated sugar 34% of the glucose, 41% of fructose and 56% of the galactose underwent oxidation. During the hyperglucemic period under the influence of insulin the oxidation was increased 15% for glucose, 24% for fructose and 87% for galactose. On the av. 36.7% of the cal. of the different hexoses was utilized in the sp. dynamic increase of heat production, and when 1 mol. sugar was oxidized 235 cal. were liberated. Control expts. in which physiol. NaCl soln. was injected showed only an insignificant rise in heat production. During the 2nd and 3rd hrs. of the injection when the transformation of the hexose was at a max. the heat production and the increase in R. Q. were inversely proportional to the concn. of the injected hexose in the blood. Although a parallelism is not always observed between the blood lactic acid curve and the heat production curve, the extent of lactic acid formation from 1 g. of assimilated hexose seems to be correlated with the sp. dynamic action and oxidation in that these are greater for the sugar from which the organism produces more lactic acid. S. M

The iodine content of the bile and thyroid gland in cattle under the influence of the seasonal changes in feeding. G. Pfeiffer. *Biochem. Z.* **230**, 290–8(1931).—An increase in the av. wt. of the thyroid glands of cattle of various ages was observed from the winter months to the summer months. It has not yet been detd. whether there is also a decline in wt. from the summer to the winter months. The I content rises both with age and with the gland wt. and reaches a max. value in cattle 5–6 years old. The change from the I-poor winter fodder to the I-rich summer fodder has no

recognizable influence upon the I of the thyroid glands. The bile secretion was found to increase with age. The I excretion in the bile during the summer is 120% higher than in winter, which shows that the I of vegetable matter is well absorbed by the animals. The I content of the feces cannot serve as an accurate guide to a study of I absorption.
S. MORGULIS

Determination of value of vitamin D preparations. II. MARTIN SCHIEBLICH. *Biochem. Z.* 230, 312–9(1931); cf. *C. A.* 23, 4971.—In testing the potency of vitamin D prepns. the healing dose does not correspond generally to the preventive dose, the former always being higher and the difference between the 2 being very variable. Detn. of the healing dose gave practically the same results either by the line test or by the x-ray examn. In such tests there is no evidence that there is any danger of error due to eating of feces, but there is apparently danger from animals licking each other. S. M.

The excretion of creatinic bodies a function of the amount of the endogenous nitrogen discharged. EMILE F. TERROINE, R. BONNET, P. DANMANVILLE AND G. MOUROT. *Compt. rend.* 191, 1473–5(1930).—This series of expts. was carried out to det. whether the behavior of creatinic bodies in metabolism can be attributed to the N of exogenous or of endogenous origin. The diet contained glucides for the energy requirement and was adequate in mineral salts and vitamins but contained no protein. Inanition expts. were carried out with pigs of 15–20 kg. and upon rats; intoxication expts. after complete inanition were carried out with pigs for the addn. of BzOH and of phlorhizin to the diet, and with rabbits for the addn. of H_3PO_4. The results of the expts. indicate that (1) the excretion of creatinine remains const. though that of endogenous N varies greatly; (2) the excretion of creatine follows that of total N; it rises with a rise of excretion of endogenous N as influenced by the diet. The creatinic bodies behave in endogenous N metabolism exactly as in exogenous metabolism. N. M. NAYLOR

Irradiated helisterol and its antirachitic power. G. MOURIQUAND AND A. LEULIER. *Presse méd.* 37, 1261–2(1929); *Bull. soc. hyg. aliment.* 18, 290(1930).—Irradiated purified cholesterol extd. from snails was found to possess practically no antirachitic power. On the other hand, cholesterol contg. the cholesteric lipoids of snails (helisterol) was found to be exceptionally active, but only after irradiation One to two drops of a 0.1% helisterol soln. was found sufficient to prevent rickets in rats and to facilitate fixation of Ca in the case of an animal fed exclusively on Pappenheimer's diet No. 85.
A. PAPINEAU-COUTURE

Clinical investigations on the antirachitic action of irradiated helisterol. G. MOURIQUAND AND A. LEULIER. *Paris méd.* 19, 409(1930); *Bull. soc. hyg. aliment.* 18, 294; cf. preceding abstract.—Clinical observations showed that irradiated helisterol has an antirachitic power comparable to that of ergosterol. This power reveals itself in the various forms of human rickets, particularly in cases of so-called "florid" rickets and in those in which the decalcification lesions do not extend to the whole diaphysis.
A. PAPINEAU-COUTURE

Vitamin A in serum and liver. BETH V. EULER. *Svensk Kem. Tids.* 42, 302–4 (1930)(in German).—There is no vitamin A in the subcutaneous fat of rabbits. There is probably no vitamin A in the serum of rabbits and sheep. The $SbCl_3$ color reaction is indefinite and is probably due to something other than carotene. A. R. ROSE

The digestion of keratin, especially the horny material of birds feathers, by fowls and mammals. ERNST MANGOLD AND JOSEF DUBISKI. *Wiss. Arch. Landw., Abt. B., Tierernähr. Tierzucht* 4, 200–21(1930).—The secondary quills of white goose feathers were fed to owls, cats, dogs and rats. Examn. of the feces showed some mech. disintegration in the case of the cat and owl, but balance expts. failed to show digestion in any of the expts. Rats on a diet deficient in cystine showed no growth that could be attributed to cystine furnished by the feathers ingested. W. GORDON ROSE

An investigation of the vitamin A content of liver meal. ANTON SOHNER. *Wiss. Arch. Landw., Abt. B., Tierernähr. Tierzucht* 4, 281–96(1930).—The vitamin A potency of liver meal was investigated to det. whether it is a suitable source of vitamin A for milk cows and young animals during the winter months. Rats were fed a diet prepd. as directed by v. Euler and v. Euler, *Zur Methodik der Vitaminprüfung* vol. 5, which was deficient only in vitamin A. Liver meal was added to the diet when noticeable loss in wt occurred. Xerophthalmia was cured and normal growth effected by 0.1 g. per day. This was equiv. to 5–10 mg. cod-liver oil. Since several of the rats lost wt. without showing any indications of xerophthalmia, other criteria, such as loss in wt., are necessary in vitamin A studies. W. GORDON ROSE

The biological values of wheat, barley and rye. ISTVÁN WEISER AND ARTHUR ZAITSCHEK. *Wiss. Arch. Landw., Abt. B., Tierernähr. Tierzucht* 4, 461–6(1930).—Goats were fed diets of hay plus wheat, hay plus barley and hay plus rye, and weighed at

intervals. The expt. showed no essential difference in the biol. values of the 3 grains.
W. GORDON ROSE

Antirachitic vitamin D. Announcement of a standard by the medical research council. ANON. *Lancet* **1930**, II, 503–4.—A quantity of ergosterol from yeast, purified and dried by methods carefully recorded, was subjected, in an accurately made alc. soln., to irradiation with the rays from a Hg arc, the phys. details of the procedure being measured and recorded with the greatest practicable accuracy. The irradiation products were carefully freed from alc., dissolved in pure, unadulterated olive oil and the vol. was adjusted to a known concn., in terms of ergosterol used. Such solns. retain their activity unchanged for 2 years if maintained at or below 0°. F. B. SEIBERT

Effect of added iron on the hematopoietic properties of dried milk. A. L. BACHARACH. *Lancet* **1930**, II, 957–8.—The recognized low hematopoietic properties of milk solids can be materially enhanced by drying appropriate quantities of an Fe salt in the milk. F. B. SEIBERT

The toxicity of vitamin D. J. B. DUGUID. *Lancet* **1930**, II, 983–5; cf. *C. A.* **24**, 5058.—The pathol. effects in animals of overdosage of vitamin D are: a tendency to increased serum Ca and blood inorg. P; a very greatly increased excretion of Ca and P, especially by way of the kidneys, involving a reduction of Ca and P retention in the body; an accumulation of Ca salts in the tissues and loss in body wt. In estg. the dosage and toxicity a large no. of factors must be taken into account. Standardization is urged. F. B. SEIBERT

The constitution of irradiated ergosterol. A. CASTILLE. *Bull. acad. roy. méd. Belg.* **10**, 319–25(1930).—A study of the absorption spectra of aliphatic geometrical isomers shows a remarkable similarity between the *cis-* and *trans-* compds. Since the same similarity is found between the spectra of ergosterol B and isoergosterol B as well as between those of dihydroergosterol A and dihydroisoergosterol A, a simple *cis-trans* isomerism due to the mobility of the secondary alc. groups is assumed. Comparison of the absorption spectra of *ergosterol A* (I) and of its irradiation product (*"vitamin D"*) points to the fact that the biol. activation is due to the gradual formation of a geometrical isomer *isoergosterol A* (II) that is identical with the active principle of vitamin D. Prolonged irradiation leads to further rearrangement into another biologically inactive modification; this transformation begins before all of I has been converted into II.
G. TOENNIES

The quantitative estimation of the glutathione content in normal and pathological tissues. III. Relationship between the development and the glutathione content in chick embryos. TOKUO KAMIYA. *Nagoya J. Med. Sci.* **5**, 1–5(1930); cf. *C. A.* **24**, 4057.—Expts. made on chick embryos show that the glutathione content increases gradually during the first half of development, reaches a max. in 12–14 days, and then gradually decreases. The liver, brain, heart, muscle and eye contain the largest percentage of the glutathione of the body and are richest in the order named. **IV. The glutathione content in various organs of pigeons fed on polished [rice] and subjected to starvation, and also of starved rabbits.** *Ibid* 6–17.—Pigeons fed on polished rice showed a decreased glutathione content in liver, heart and muscle proportional to the no. of days of the expt. The adrenal glands, spleen and blood showed an increase. Starvation produced the same result, but to a greater degree. Symptoms of polyneuritis appeared after 15–18 days in pigeons fed on polished rice and later in those fed on half-polished rice. **V. Relationship between glutathione content and neurotomy in muscles of pigeons fed on polished and unpolished rice.** *Ibid* 18–23.—Pigeons were subjected to neurotomy of the sciatic nerve of the right leg, the left serving as control. The wt. of the right leg did not increase as rapidly as that of the left and the glutathione content of the muscle subjected to neurotomy showed an increase proportional to the no. of days elapsed since the operation. This was true for pigeons fed on polished rice as well as unpolished rice; but in the control muscles, the glutathione content decreased more rapidly in the former case. A. WIEBEN

Ergosterol and some of its derivatives (DE BOER) **10.**

DRUMMOND, J. C., AND HILDITCH, T. P.: **The Relative Values of Cod Liver Oils from Various Sources.** London: H. M. Stationery Office. 135 pp. 1s. Reviewed in *Chemistry & Industry* **50**, 160(1931).

F—PHYSIOLOGY

E. K. MARSHALL, JR.

Excitant substance in the central nervous system. L. HABERLANDT. *Arch. ges. Physiol. (Pflügers)* **223**, 171–9(1929).—The excitant action of emulsions of the cerebrum

or midbrain when injected into frogs is due to a substance which is sol. in water, but not in alc. or Et_2O; it is dialyzable, and is decomposed when heated. B. C. A.

Existence, origin and significance of the so-called lutein colloid. A. ALBANESE. *Arch. ist. biochim. ital.* 2, 269–80(1930).—Discussion of previous work, together with new exptl. results, indicates that the ruby-red test is not sp. for the lutein colloidal substances, that the presence of this colloid is not sufficient for the diagnosis of a gravid lutein body, and that the so-called colloid encountered in either the menstrual or gravid lutein body is merely a metamorphic blood deriv., which is accompanied by involutive, atrophic phenomena of the lutein body itself. B. C. A.

Amylase content of the milk of various animals. R. SCHENK. *Arch. wiss. prakt. Tierheilk.* 58, 375–84(1928).—Human milk contains a considerable quantity of amylase; colostrum-free milk of the cow, horse, dog, cat and guinea pig contains only traces, while neither milk nor colostrum of the goat contains amylase. The markedly higher amylase content of the colostrum of the other animals, falling with the progress of lactation, indicates that the enzyme originates in the colostrum. B. C. A.

Glutathione content of human placenta and denervated gastrocnemius of the toad. J. DI LEO LIRA. *Compt. rend. soc. biol.* 102, 469–70(1929).—The former contains 0.029–0.038%, the latter 0.014–0.018% (normal), 0.012–0.017% (denervated) of glutathione. B. C. A.

Lipogenic and antilipogenic action of hormones as cause of obesity and leanness. A. LUBLIN. *Klin. Wochschr.* 8, 2276–8(1929).—Hyperfunction of lipogenic hormones (*e. g.*, insulin) causes obesity and of antilipogenic hormones (*e. g.*, adrenaline, thyroxine, pituitary hormone) causes leanness. Intravenous injection of thyroxine (1 mg.) causes a transient rise in blood sugar (*e. g.*, 0.110–0.130 g. per 100 cc.). B. C. A.

Hydremia in alimentary hyperglucemia. M. N. KALLINIKOVA. *Russ. J. Physiol.* 13, 193–7(1930).—Detn. of hemoglobin and water in the blood of children, taken at various times after ingestion of sugar, show that hydremia is not assocd. with hyperglucemia. B. C. A.

Cholesterolemia in alimentary hyperglucemia. M. N. KALLINIKOVA AND G. D. OBRAZTZOV. *Russ. J. Physiol.* 13, 198–203(1930).—In children alimentary hyperglucemia is assocd. with cholesterolemia, which attains its max. value 15–30 min. after ingestion of sugar. No general parallelism is found between the blood-cholesterol-time curves and the dextrose-time curves. B. C. A.

Blood lipase in alimentary hyperglucemia. E. T. MINKER-BOGDANOVA AND G. D. OBRAZTZOV. *Russ. J. Physiol.* 13, 204–9(1930).—Max. variations of the lipase-time curves of blood following the ingestion by children of large quantities of sugar coincide with the maxima of the dextrose and fat content-time curves. The types of lipase-time curves found for different individuals correspond either with the dextrose-time curves or with their mirror images. B. C. A.

Absorption of water, 0.2% hydrochloric acid, gastric juice, ethyl alcohol and various chlorides by the dog's isolated stomach. R. O. FAITELBERG. *Russ. J. Physiol.* 13, 224–36(1930).—From 22 to 31% of water introduced into the isolated small stomach of the dog is absorbed within 60 min. Addn. of HCl to 0.2% or of NaCl to 0.9% reduces the percentage absorption to about 17%. Natural gastric juice in some cases undergoes resorption, assocd. with diminution in acidity. The abs. but not the relative amt. of chlorides resorbed from hypertonic solns. increases with concn. Absorption of alc. from 10 and 20% solns. is complete within 60 min., and amounts to 90% in the case of 40% alc. solns. The velocity of absorption of chlorides and of alc. is greatest during the 30 min. following introduction. B. C. A.

The variations of the specific gravity of the plasma and the means available for altering it. NORMAN S. MOORE AND HAROLD J. STEWART. *J. Clin. Investigation* 9, 423–39(1930); cf. *C. A.* 24, 3828.—For comparable results the same anticoagulant must be used, heparin being employed in these expts. Normal specimens of blood show a remarkable constancy of the sp. gr. of plasma and of plasma proteins, provided the samples are taken at the same time each day. In patients suffering from heart disease who were in water balance the max. daily variation in sp. gr. was 0.0004. In 2 normal individuals the variations over a period of 14 months were 0.0015 and 0.0011. Arterial blood showed lower values than venous. Intravenous injection of normal saline soln. into dogs lowered the plasma sp. gr. and protein. Administration of 1 l. of water by mouth to human beings had slight effect. After hemorrhage a decline in these values was followed by a return to normal after 4 days. The injection of gum acacia in glucose soln. slightly increased the sp. gr., but lowered the proteins by diln. J. B. BROWN

Carbon dioxide and oxygen tensions of the mixed venous blood of man at rest. DICKINSON W. RICHARDS, JR., AND MARJORIE L. STRAUSS. *J. Clin. Investigation* 9,

475–532(1930).—Certain aspects of the process of equilibration of lung gases with incoming venous blood are discussed. Equil. can be regularly established for CO_2 with certain high O mixts. and for both CO_2 and O with certain low O mixts. J. B. B.

Studies on the Arneth count. XVII. The effect of alterations of the serum-calcium level on the count. DAVID R. CLIMENKO. *Quart. J. Exptl. Physiol.* **20**, 369–77(1930); cf. *C. A.* **24**, 5351.—Irradiated milk taken by humans, colloidal Ca orally administered to rabbits, and physiol. saline soln. intravenously injected into rabbits produced no change in the Arneth count or the serum-Ca level. Colloidal Ca injected intramuscularly into rabbits and $CaCl_2$ intravenously raised the serum-Ca level and produced a regenerative deflection of the count. Intravenous injections of hypotonic solns. produced no effect on the serum-Ca level but caused a regenerative deflection of the count. RACHEL BROWN

The reformation of muscle glycogen destroyed by work. G. DEBOIS. *Compt. rend. soc. biol.* **103**, 546–8(1930).—Contraction of the paw muscles of cats (anesthetized or decerebrated) was effected by elec. stimulation of the sciatic nerves. The integrity of the vagi nerves is essential for the reformation of muscle glycogen after work; the left vagus alone is sufficient. The glycogen lost after section of the cervical medulla, vagotomy or pancreatectomy is fully restored by the injection of 30 units of insulin. B. C. BRUNSTETTER

The effect of the injection of synthetic thyroxine on the carbon and nitrogen in urine. GEORGES FONTÈS AND LUCIEN THIVOLLE. *Compt. rend. soc. biol.* **105**, 558–9(1930).—Two adult male dogs of the same wt. and age were kept on a const. diet throughout the expt.: after a month, the vol. of the urine, as well as its C and N contents, was recorded daily for 3 weeks (I); the same detns. were made over a period of 2 weeks in which 1 mg. of thyroxine was injected daily (II), over a period of 2 weeks in which 2 mg. of thyroxine was injected daily (III) and lastly, over a period of 2 weeks in which no injections were made (IV). Variations of wt. over each period were recorded. The av. amts. of C and N per day in g. were: I, 3.60, 5.04; II, 4.12, 5.66; III, 4.15, 5.72; and IV, 3.62, 4.90. The C/N ratios for the 4 periods were 0.71, 0.72, 0.71 and 0.73. The vol. of urine was not altered by thyroxine treatment. The av. wt. changes were: I, +150; II, −450; III, −400; and IV, +250. B. C. BRUNSTETTER

The effect of thyroidectomy with and without injections of thyroxine on the carbon and nitrogen in urine. GEORGES FONTÈS AND LUCIEN THIVOLLE. *Compt. rend. soc. biol.* **105**, 559–61(1930); cf. preceding abstr.—The same diet and technic were used in this expt. A 15-kg. dog was used. The data obtained support the conclusion that thyroidectomy alters the C/N ratio of the urine, but that injections of thyroxine do not. The thyroid gland exerts functions other than the elaboration of thyroxine. B. C. BRUNSTETTER

The effect of delivery on the protein equilibrium of the serum. CH. ACHARD, M. BARIÉTY AND A. CODOUNIS. *Compt. rend. soc. biol.* **103**, 1064–6(1930).—The total protein, the albumin and the globulin of the sera of 9 women at the time of delivery and 10 days after delivery were detd. The total protein and albumin are slightly less than normal and can be accounted for by the hydremia of pregnancy. In 6 of the cases, the total protein was decreased 10 days after delivery; in 5 cases the albumin was decreased, while in 5 cases the globulin was increased. B. C. BRUNSTETTER

The organic bases and amino acids in normal human urine. SAKISABURO WADA *Acta. Schol. Med. Univ. Imp. Kioto* **13**, 187–99(1930).—From 300 l. of normal human urine, the following compds. were isolated: leucine, alanine, *l*-proline, *d,l*-proline, isoleucine, valine, phenylalanine, aspartic acid (?), glutamic acid, hippuric acid, creatine, creatinine, histidine, methylguanidine, betaine (?), choline, methyl pyridylammonium hydroxide, lysine, xanthine, *l*-methylxanthine (?), adenine, hypoxanthine, heteroxanthine and *p*-xanthine. H. J. DEUEL, JR.

Cortin, the vital hormone of the adrenal cortex. FRANK A. HARTMAN. *Endocrinology* **14**, 229–32(1930).—The injection of cortin (an ext. prepd. from the adrenal cortex) not only prevented the development of the usual symptoms following double adrenalectomy but allowed the animals (cats) to survive indefinitely (170 days in the longest expt.) as well as to increase in wt. Its potency was also demonstrated in bringing about the recovery of 2 animals in acute adrenal insufficiency. The blood urea is lowered from the high level occurring in adrenal deficiency. A relationship was shown to exist between the rate of growth of adrenalectomized rats and cortin injection. H. J. DEUEL, JR.

The effects of growth-promoting and gonad-stimulating principles of the anterior lobe of the pituitary on basal gaseous metabolism in the rat. MILTON O. LEE AND JULES GAGNON. *Endocrinology* **14**, 233–42(1930).—The subcutaneous administration

of the gonad-stimulating principle of the anterior lobe of the pituitary daily for periods of 8 to 24 days caused no significant change in the basal metabolism in rats. Identical results were obtained on exts. of the fresh gland and on that isolated from the urine of pregnant women. On the other hand, the intraperitoneal injection of these prepns. was effective in reducing the metabolic rate of 10 of the 18 animals used after several daily injections. The lowered metabolism continued 6 to 14 days after the treatment had stopped. H. J. DEUEL, JR.

The metabolism of the isolated frog heart. A. J. CLARK, C. P. STEWART AND R. GADDIE. *Proc. Roy. Soc. Edinburgh* **50**, 297–303(1930).—Expts. were made on isolated frog heart perfused with Ringer's soln. either with or without glucose. Even in the presence of serum, glucose and insulin the carbohydrate metabolism represents only a fraction of the total metabolism. The protein catabolism can account for somewhat over 50% of the total O consumption. There is no evidence that this organ uses fat as detd. by the amt. present. The heart does not synthesize glycogen from protein. It is possible that an unknown factor essential for carbohydrate metabolism is absent in these artificial expts. although the ease with which the heart utilizes non-carbohydrates sources of energy suggests that the metabolism of this foodstuff is not a primary process which produces muscle contraction. These results are at variance with those obtained earlier on dog heart. H. J. DEUEL, JR.

Physiological chemistry of the blood in the tropics. W. BORCHARDT. *Arch. Schiffs-Tropen-Hyg.* **34**, 608–12(1930). H. EAGLE

The iodine content of the normal thyroid of albino rats. G. SANKARAN. *Indian J. Med. Research* **18**, 563–70(1930).—Thyroids average an I content of 0.018%, independent of sex and age. Thyroid weight is proportional to body weight. H. E.

The significance of the parathyroid hormone for the regulation of the calcium economy. CHRISTIAN BOMSKOV. *Klin. Wochschr.* **9**, 2065–6(1930).—A preliminary report. H. EAGLE

The water-binding relationships of child blood plasma. J. JOCHIMS. *Klin. Wochschr.* **9**, 2115(1930).—Viscosity is a reliable index of the water-binding power of the plasma colloids. In child plasma it varies between 0.095 and 0.108. During hydremia in the child there is a parallel fall in plasma viscosity and protein: the sp. viscosity remains const., indicating that the excess water in the plasma is free and not bound by plasma colloids. H. EAGLE

Choline and choline esters in the blood. H. BOHN. *Klin. Wochschr.* **9**, 2147–8 (1930).—A protein-free ext. of human blood contg. choline, when injected into rabbits or cats, causes a very pronounced fall in blood pressure. Choline esters are known to be many thousand times as active in this respect as choline, and B suggests that the choline in the blood (1.5–2 mg. %) is, in part at least, in the form of an ester with, *e. g.*, AcOH. In essential hypertension there is a low blood choline. H. EAGLE

Glucolysis and increase in acidity in tissue cultures, and analogous phenomena in the organism. A. A. KRONTOVSKII AND M. A. MAGATH. *Klin. Wochschr.* **9**, 2165–8 (1930).—The oxidation of glucose to lactic acid is the most important source of energy in tissue cultures. This type of metabolism may be characteristic of active regenerative processes even in the organism. The CO_2 formed results both from respiration and from the action of the lactic acid upon the $NaHCO_3$ of the medium. Changes in tissue cultures are analogous to changes observed in ischemia, inflammation, wound healing, regeneration, etc. H. EAGLE

Milk secretion and menformone. S. E. DE JONGH AND ERNST LAQUEUR. *Klin. Wochschr.* **9**, 2344–6(1930).—The administration of menformone to male guinea pigs causes lactation. It is interesting to note that large quantities, 50 units twice daily for 4 weeks, cause a preliminary mammary hypertrophy; if this dose is then suddenly decreased, lactation begins within 2–3 days and continues for as long as 40 days if constantly decreasing quantities of menformone are injected. The authors point out the complete analogy to conditions in the pregnant woman. H. EAGLE

The protein content of the urine of patients with normal kidney function. BRUNO MINZ. *Klin. Wochschr.* **9**, 2352–3(1930).—Using sulfosalicylic acid as a pptg. agent and solns. of casein as a nephelometric standard, M. finds that the urine of normal subjects invariably contains some protein, ranging from 0.14 to as high as 13 mg. %. The Esbach method can detect only 25 mg. %. H. EAGLE

The theory of diuresis (urine excretion). HELLMUT MARX. *Klin. Wochschr.* **9**, 2384–8(1930).—The blood of a fasting dog contains a substance which inhibits the diuresis caused by water. The significance of this finding is discussed, particularly in the light of the fact that a pituitary ext. has a qualitatively similar effect. H. EAGLE

Substances in human urine and diagnoses of pregnancy. M. ARON AND M. KLEIN.

Compt. rend. soc. biol. 103, 702–4(1930); *Physiol. Abstracts* 15, 248–9.—The action of human urine on the thyroid glands of guinea pigs and rabbits demonstrates that the substance in the urine producing this effect is the hypophyseal hormone. This sp. reaction is obtained with all urines, whether from men or women, but the urine of pregnancy only can affect the genital organs. This latter effect is due, not to the hypophyseal, but to a placental substance. G. G.

Pulmonary chemical sensibility studied by means of the isolated head. A. Pi Suñer and J. Puche. *Compt. rend. soc. biol.* 103, 735–6(1930); *Physiol. Abstracts* 15, 226. G. G.

Secretion of cerebrospinal fluid. T. Falkiewicz. *Compt. rend. soc. biol.* 103, 821–3(1930); *Physiol. Abstracts* 15, 253.—The secretion of the cerebrospinal fluid is stimulated by hypophyseal ext., pilocarpine and atropine; it is not increased by adrenaline, thyroxine, caffeine, $AmNO_3$, theobromine, salicylate of Na, Br, I, luminal and hypertonic or hypotonic solns. of NaCl. The hypophysis is the biol. regulator of this secretion. The neg. results are opposed to the theory of transudation and confirm that of sp. secretion. G. G.

The storage of iodine in living tissues. W. Weber. *Schweiz. med. Wochschr.* 15, 237–9(1930); *Bull. Hyg.* 5, 942.—The thyroid is known to store appreciable amts. of I; other glands such as the ovary and suprarenal store the element but in considerably smaller quantities. W. fed rabbits KI and injected solns. of the salt in the blood to det. whether the I content of the tissues was raised. Tissues such as the liver, heart, lungs and spleen were so low in I that the amt. might be attributed to exptl. error. The value for the kidneys was higher, but this might be attributed to the urine on the tubules. The urine contained considerable amts. of I. After 24 hrs. 50–60% of the I consumed had been excreted. George R. Greenbank

The content of glutathione of the blood in high altitudes and on exposure to natural Alpine sun. J. von Deschwander. *Strahlentherapie* 39, 278–82(1931).—D. found that the glutathione content of the blood and that of the red blood cells are considerably increased at altitudes of 1300–500 m. above sea level. After one hour's irradiation with natural Alpine sun, the glutathione content of the blood and the quotient glutathione: erythrocytes decrease. This means that the glutathione content of the red blood cells decreases. Conclusion: The sp. respiration function of the blood and that of the red blood cells are increased at these altitudes, while by irradiation with natural Alpine sun this function is decreased. Frederick R. Greenbaum

The minute volume and gaseous metabolism of the artificially perfused mammalian intestine. H. F. Roese. *Arch. ges. Physiol.* (*Pflügers*) 226, 184–9(1930).—The O_2 consumption of denervated mammalian intestine is 4.5 cc. per kg. per min., but varies considerably with time. The R. Q. is greater than unity. Arthur Grollman

Ammonia formation and sugar utilization in artificially perfused mammalian intestines. H. F. Roese. *Arch. ges. Physiol.* (*Pflügers*) 226, 190–7(1930).—Intestines perfused by a Starling heart-lung prepn. form appreciable quantities of NH_3 presumably as a result of bacterial decompn. Glycocoll is resorbed by the intestine but is deaminized neither by the intestinal wall nor by the lung of the heart-lung prepn Urea, although retained by the intestinal wall, is not converted to NH_3. The sugar utilization of the intestine is 1.75–1.94 g. per kg. per hr., only 20% of which is oxidized. Arthur Grollman

Effect of sleep, abstention from sleep, and physical work on the blood chemistry. M. Hochrein, J. Michelsen and H. Becker. *Arch. ges. Physiol.* (*Pflügers*) 226, 244–54(1930).—Abstention from sleep for a night resulted in an increase in the NaCl, total base, total CO_2 and PO_4^{---} of the blood. Physical exercise produced greater changes in the blood chemistry of subjects deprived of sleep, during the preceding night, than in normal rested subjects. Arthur Grollman

The temperature coefficient of oxygen utilization by surviving organs. E. Schmutzler. *Arch. ges. Physiol.* (*Pflügers*) 226, 294–304(1930).—The O_2 consumption of isolated perfused limbs of the dog remained const. for 3–4 hrs. Cooling and subsequent rewarming did not affect this O_2 consumption. The temp. coeff. for the O_2 consumption was const. and equal to 3% of the value at 35°, for each degree change in temp. A similar linear relationship also occurred in goose blood over the temp. range of 17–39°, the coeff. being 4% of the value at 35°. Arthur Grollman

The effect of reduced air pressure on animals. III. The effect of varying degrees of reduced air pressure. W. Linzel and T. Radeff. *Arch. ges. Physiol.* (*Pflügers*) 226, 307–18(1930); cf. *C. A.* 24, 4544.—White rats were kept for 3 weeks under reduced air pressures of varying degrees. The blood corpuscles increased at air tensions corresponding to 2000 and 4000 m. altitude, but little at higher altitudes. The total hemo-

globin and blood vols. increased in inverse proportion to the air pressure. The heart wts. did not increase except at pressures corresponding to altitudes of 6000 meters or more. ARTHUR GROLLMAN

A chemical investigation in Victoria (Australia) of the blood of cattle and sheep. JOAN H. NORRIS. *Australian J. Exptl. Biol. Med. Sci.* **7**, 3–4(1930); cf. *C. A.* **24**, 5809.—The mean values found for inorg. P (mg./100 cc.), total P and Fe, resp., were: 4.44, 10.13 and 60.54 for 26 steers, and 6.63, 12.59 and 57.92 for 22 cows. C. G. KING

A chemical study of the liver during inanition. L. VAUDIN, M. JAVILLIER, H. ALLAIRE AND MAD. SCHIRMER. *Bull. soc. chim. biol.* **12**, 894–902(1930).—A dog receiving water only until its weight had dropped from 7 to 5.1 kg. showed the following % loss (dry wt.) in liver constituents compared to a control kept on a normal diet: glycogen and glucose 74.8, ash 33.7, insol. ash 48.1, ether ext. 31.8, cholesterol 24.4, unsaponifiable matter 10.5, glycerides 45.7, lecithin P 25.1, nucleoprotein P 16.5, N 18.3, total loss in dry wt. 27.2%. C. G. KING

The pituitary posterior hormone in fat metabolism. W. RAAB. *Endocrinology* **14**, 385–8(1930).—Pituitrin promotes the absorption and destruction of circulating fat by the liver through a nervous pathway starting in the tuber cinereum and running through the cervical spinal cord and the abdominal splanchic to the liver. Any disturbance of the pituitary-mesencephalic system leads to obesity. Arterio-venous fat detns. suggest that pituitrin does not affect the fat deposit directly. There seems to be a relation between the pituitrin-nervous mechanism and chem. heat regulation. MARY E. LEAR

Crystalline cholesterol in the post-retinal fluid. ALBERTO J. SCHIVO AND LUIS N. PIZZORNO. *Ann. farm. bioquim.* **1**, 160–6(1930). B. S. LEVINE

Protein sugar in the blood plasma of the horse. H. BIERRY. *Compt. rend.* **192**, 240 1(1931); cf. *C. A.* **25**, 1270.—The protein sugar content of the blood plasma varies with the species and within the species with the individual. Furthermore, it is possible to provoke in the same individual important variations in the protein sugar content through the injection of adrenaline and insulin. In the blood plasma of the horse glucidic complexes combined with protein (protein sugar) constitute about $^2/_3$ of the total sugar. The latter oscillates around 2 g. per l. of plasma. Marked individual variations occur. B. S. LEVINE

Combining the values of optic density and viscosity of a suspension for the determination of the number and volume of the dispersed elements. G. ACHARD. *Compt. rend* **192**, 242–4(1931).—A. made a study of the relation between viscosity and no. of red blood cells on the one hand, and optic d. and no. of red blood cells on the other. An attempt was made by combining the viscosity and optic d. value to derive an empirical formula which would make possible the detn. of the vol. and the no. of the dispersed elements. B. S. LEVINE

A metabolic study of desiccated suprarenal medication in man. R. G. HOSKINS AND F. H. SLEEPER. *Endocrinology* **14**, 109–11(1930).—Before the medication was begun records were made of a series of clinical lab. detns. The suprarenal substance was administered by mouth in dosages varying from 18 to 90 gr. daily for 54 to 108 days. The results are recorded in a table. From the viewpoint of lab. findings they are neg. Likewise no significant mental changes are observable. The general deviations observed were such as are usual in any medically selected group B. S. LEVINE

Purification of the male hormone by high-vacuum distillation. E. DINGEMANSE, J. FREUD, S. KOBER, E. LAQUEUR AND A. P. W. MÜNCH. *Proc. Acad. Sci. Amsterdam* **33**, 1206–9(1930).—The method of fractionation is described and a schematic outline of the fractions obtained is presented. It is concluded that the male hormone can be brought to a high degree of purity through high-vacuum distn. At 90° with pressure of 0.001 mm. the hormone is found in the distillate, and at 80° in the residue. Fractional distn. offers the possibility for the sepn. of the male from the female hormone. Also in *Naturwissenschaften* **19**, 166(1931). B. S. LEVINE

The quantitative knowledge of cerebral lipoids. (A dissertation.) ERICK BACKLIN. *Upsala Läkareförenings Förhandl., N. F.* **35**, 105–83(1930).—The object was to det. the changes occurring in the cerebral lipoids in the psychoses. The chemistry of the lipoids of the brain and methods for the quant. study of cerebral lipoids are reviewed. A new method is described which requires only 30–50 mg. of the brain substance for the detn. of (*a*) cholesterol, (*b*) the fraction contg. unsatd. phosphatides in greater part, (*c*) the satd. phosphatides and (*d* and *e*) cerebrosides with satd. and unsatd. fatty acid radicals. Results obtained by this method indicated that it is reliable. The water content of the brain substance was detd. In the autolysis taking place in the cerebral

lipoids during the first 24 hrs. postmortem, demonstrable changes actually occur.
B. S. LEVINE

Effect of composition of air on the growth and mortality of the chick embryo. A. L. ROMANOFF. *J. Morphol. Physiol.* **50**, 517(1930); cf. *C. A.* **24**, 4087.—Studies were made upon fertilized hen eggs. Continuous exposure to 0.4% of CO_2 in the air stimulated growth during the first part of the embryonic period. A high CO_2 and a diminished O_2 content decreased the size and increased the mortality of the embryos. Temporary exposures to high CO_2 concn. of 24- or 48-hr. periods decreased the size of the embryos with no apparent injuries. C. M. MCCAY

The phosphorus partition in normal whole blood. BURNHAM S. WALKER AND MILDRED E. HUNTSINGER. *J. Lab. Clin. Med.* **16**, 247–52(1930).—The total P content of normal whole blood is 39.2 mg. per 100 cc. The inorg. phosphate P appears to be 9.7% of the total P; the acid-sol. P 68.1%; the acid-sol. org. P (ester P) 58.3% and the lipin or lecithin P 36.0%. The P detns. were made by the method of Fiske and Subbarow (*C. A.* **20**, 1092). E. R. MAIN

The effect of splenectomy on changes in the blood at high altitudes. ANTONIO CHIATELLINO AND STEFANO GOLDBERGER. *Arch. sci. biol.* (Italy) **15**, 407–32(1930).—The studies were made on 3 normal and 3 splenectomized dogs which had been kept on Colle d'Olen for 6 weeks. The percentage increase in red blood corpuscles for the normals was 5.0, 8.9 and 0.6; for the splenectomized animals 50.0, 22.3 and 33.3. The percentage increase in hemoglobin was, resp., 14.3, 19.5, 11.8 and 31.8, 58.0, 11.7. There was also an increase in leucocytes which appeared rather late, but there was no marked difference between the 2 groups. Blood smears from the splenectomized animals showed numerous Jolly bodies and a few normoblasts; the controls also presented a similar picture but with much less frequency. The resistance of the corpuscles was greater in the splenectomized than in the normal animals. On returning to lower altitudes, there was a marked diminution of all values which approached the initial values; the resistance of the corpuscles, however, remained higher than the initial value.
PETER MASUCCI

Gaseous exchange of the testicle. A. CHIATELLINO. *Arch. sci. biol.* (Italy) **15**, 433–44(1930).—The respiratory exchange of the testicles of normal decerebrated, narcotized and curarized dogs was detd. In the first 2 groups, the blood flow in the organ was noticeably less than in the curarized group. In those narcotized the R. Q was on an av. 45.7 cc. per min. per 100 g. of organ. The O_2 consumption was on an av. 3.47 cc. per 100 g. of organ; the CO_2 production was on an av. 3.00 cc. per min. per 100 g. of organ. The respiratory exchange in the left and right organs of the same animal corresponded perfectly. There were marked differences, however, between individual animals; in general with an increase in blood flow, there was a decrease in the respiratory exchange. PETER MASUCCI

Variations in the nonprotein nitrogen of the blood during fatigue. UGO RONDELLI AND S. CHIABRERA. *Minerva med.* **1930**, I, 65–70.—The purpose of this investigation was to det. the relation between muscular fatigue, hyperthermy and protein metabolism. From the results obtained on 6 subjects, the conclusion is drawn that the increase in nonprotein N of the blood which accompanies muscular fatigue (running) is independent of the energy spent and of the hyperthermy from fatigue. The increase in the nonprotein N is attributed to a change in equil. between the tissues and blood plasma. PETER MASUCCI

Choline and adrenals. GAETANO VIALE AND TEODORO COMBES. *Arch. fisiol.* **28**, 25–32(1930).—Injections of adrenaline cause the passage of choline from the adrenals into the circulation. The sopradiaphragmatic section of the vagus has no influence on the choline content of the adrenals. A. E. MEYER

Experimental determination of sex and the sterility by hormone action. B. PANIZZA. *Arch. fisiol.* **28**, 51–68(1930).—See *C. A.* **25**, 329 A. E. MEYER

The metabolism of alcohol by man at high altitudes. A. BORNSTEIN AND A. LOEWY. *Biochem. Z.* **230**, 51–67(1931).—The alc. content of the blood rises more rapidly and to a higher level at high altitudes than in the plains, but after the max. concn. has been reached the loss of the alc. from the blood proceeds at the same rate at high or low altitudes. The min. vol. as well as the frequency of the respiration is little affected under both conditions. The R. Q. was found to be regularly lower in the mountains than in the plains, and after the consumption of alc. it fell much more so that in the mountains the R. Q. often became that of pure alc. oxidation. Under neither condition did alc. exert any sp. dynamic action, except when sugar was given together with the alc.
S. MORGULIS

Phosphoration, lactic acid formation and phosphatase activity in muscle pulp and

in muscle powder. J. Bodnár and Béla Tankó. *Biochem. Z.* **230**, 228–32(1931).—The lactic acid formation of muscle pulp decreases during preservation in direct ratio to its loss of ability to esterify H_3PO_4. The H_3PO_4-esterifying substance is completely retained in the powder prepd. from muscle pulp with alc. ether, or with acetone ether. The inability of the muscle powder to form lactic acid is attributed to the diminished content of phosphatase, since the loss of phosphatase activity is parallel to the diminution in lactic acid formation. S. Morgulis

Fate of fructose in the animal organisms. II. Do the digestive juices cause a change of fructose to glucose? W. W. Oppel. *Biochem. Z.* **230**, 269–84(1931); cf. *C. A.* **25**, 1858.—When a fructose soln. is preserved under toluene in a thermostat with a mixt. of digestive juices (gastric, pancreatic and intestinal) at different p_H values there is no formation of aldoses even after 20 hrs. Shorter preservation of similar mixts. but without toluene likewise fails to bring about any transformation of fructose to an aldose, although the intestinal sucrase causes considerable hydrolysis of sucrose in the same period of time. S. Morgulis

Studies on blood glucolysis. II. The pyrophosphate fraction and glucolysis. H. K. Barrenscheen and Béla Vásárhelyi. *Biochem. Z.* **230**, 330–46(1931); cf. *C. A.* **25**, 1544.—The pyrophosphate content of different bloods shows considerable variation, increasing in the following order: horse<cow<dog<rabbit<guinea pig<man<pig. In man the pyrophosphate fraction constitutes relatively the highest portion of the acid-sol. org. P. Except for the blood of the pig, with its very large pyrophosphate content but no glucolytic power, the glucolytic ability of the various bloods seems to be correlated with their pyrophosphate content. During glucolysis there is an increase in the pyrophosphate which is entirely accounted for by the decrease in inorg. P, but when the glucolysis is accelerated by the addn. of SO_4 ions the pyrophosphate diminishes instead. Neither the feeding of large amts. of glucose nor the preliminary injection of insulin has any effect upon the pyrophosphate fraction of the blood P. The pyrophosphate is present only in the erythrocytes, apparently in some org. combination because it cannot be easily isolated. The blood and cells contain a pyrophosphatase which sets free P from pyrophosphate, the enzyme being inhibited in its action by F. S. Morgulis

The solubility, dissociation and tension of carbon dioxide in urine. Fritz Mainzer and Marga Bruhn. *Biochem. Z.* **230**, 395–410(1931).—Detns. made on 20 urines gave the following results: the soly. $\alpha_{(CO_2,\ 38°)} = 0.441 - 0.514$; $p_{KI} = 5.81 - 6.30$; and $P_{(CO_2,\ 38°)} = 13.3 - 242.4$ mg. Hg. From this it seems that the CO_2 tension of the urine could not have the physiol. significance as representing the tension in the tissues. S. Morgulis

The cholesterols in structural combinations in protoplasm. V. Studies on adrenals from cattle. G. Pfeiffer. *Biochem. Z.* **230**, 438–45(1931); cf. *C. A.* **24**, 4826.—A special procedure is described for the hydrolysis of the adrenals with 2% NaOH. In 100 g. of fresh substance was found 0.2753 g. total cholesterol, of which 56.6% were cholesterol and oxycholesterol (the latter alone representing 17.5%) and 43.2% cholesterol esters. Cholesteryl palmitate was 2.3% and the oleate 9.1%; oxycholesteryl oleate was 31.9%. The high cholesterol content of the adrenals is thought to be due to the destruction of erythrocytes for the building up of the adrenal hormon. The endogenous synthesis of cholesterol in the adrenals is considered as improbable. S. Morgulis

The significance of the conjugated bile acids in fat resorption. IV. F. Verzar and A. von Kuthy. *Biochem. Z.* **230**, 451–7(1931); cf. *C. A.* **23**, 4957.—The objection to the hypothesis that fat is absorbed in the intestinal tract as the water-sol. combination of fatty acids with bile acids could be based upon the fact that there is never enough bile acid present to convert all fatty acids into a diffusible state. Expts. made on isolated and washed out segment of intestines of living animals show that a given amt. of bile acid promotes the absorption of much more fatty acid than could be made diffusible in tests *in vitro*. It is therefore assumed that the bile acids become adsorbed on the epithelial cells of the mucous membrane where the fatty acids become converted into diffusible forms. This is corroborated by the finding that even hrs. after the administration of bile acids these can be demonstrated in the mucous membrane though not in the lumen of the intestine. The adsorbed bile acid-fatty acid combination is presumed to undergo hydrolysis, the bile acids being then ready to take up more fatty acids. S. Morgulis

The role of the pyloric sphincter in the control of gastric acidity. Robert Elmen and A. P. Rowlette. *Arch. Surg.* **22**, 426–37(1931). John T. Myers

The zinc content of the liver of the rat in relation to growth. Gabriel Bertrand

AND MME. Y. BRANDT-BEAUZEMONT. *Compt. rend.* **191**, 1410–1(1930); cf. *C. A.* **24**, 5358.—With the same methods of technic and analysis as previously described, expts. were made to det. the Zn content of the livers of rats at various stages of growth: at birth, at 15 days (near weaning), at 30 days and at 7 months. It was shown that the quantity of Zn per 100 g. of liver decreased with age, there being about 3½ times more of metal at the time of birth than in the adult rat. Because of this storage of Zn at birth, it seems that the role of Zn in nutrition is more important in the adult than in the new-born. N. M. NAYLOR

The mucin of the articular fluids. CH. ACHARD AND M. PIETTRE. *Compt. rend.* **191**, 1412–4(1930).—In the expts. described, synovial mucin is purified by repeated pptns. from a water soln. with acetone. It is first obtained as a thick, viscous mass, but with further purification, as a dry powder. Synovial mucin averages 0.7% S, while the mean content of S in blood serum averages 1.4%. The sp. viscosity of synovial mucin is 5.389; that of blood serum is 1.090. The synovial mucin described compares favorably with true mucin (1) by its soly. in excess HCl and its slight soly. in excess AcOH and (2) by the fact that its content of sulfur is similar to that obtained for saliva mucus (Hammarsten) and for tendon mucus (Loebisch). N. M. NAYLOR

Threshold relationships of testis hormone indicators in mammals: the rat unit. CARL R. MOORE AND T. F. GALLAGHER. *J. Pharmacol.* **40**, 341–49(1930); cf. *C. A.* **24**, 3547.—The order of sensitivity in the rate of testis hormone indicators was: (1) spermatozoön motility test; (2) prostate cytology test; (3) seminal vesicle, Cowper's gland and vas deferens tests; (4) elec. ejaculation test. The rat unit is defined as the minimal daily amt. required to maintain 50% of castrated animals in a normal condition, the indices being a normal prostate gland and seminal vesicle. One rat unit is approx. equal to 6 bird units. C. RIEGEL

The chemistry of muscular contraction. OTTO MEYERHOF. *Lancet* **1930**, II, 1415–22.—The hydrolysis of creatinephosphoric acid in muscle is of the utmost importance in muscle contraction. The lactic acid-forming system is analyzed and a "hexokinase" discussed. Similarities between the glucolytic function of muscle and the fermentative function of yeast are pointed out. The importance of phosphoric esters, pyrophosphate and adenylic acid in muscle or enzyme exts. is stressed. All vertebrates are found to contain creatinephosphoric acid in their striated muscles, and all classes of invertebrates utilize argininephosphoric acid. F. B. SEIBERT

The regulation of oxygen consumption in animals with variable alveolar gaseous tension. H. J. JORDAN. *Arch. néerland. physiol.* **15**, 198–212(1930).—Diving birds, amphibia, molluscs and insects are considered. The O content of the lungs may vary more than 10% with only a slight difference in consumption. B. A. SOULE

Iron in normal and pathological tissues and its biological significance. I. Iron content of the organs of various classes of animals. KENZUI KOJIMA. *Nagoya J. Med. Sci.* **5**, 34–48(1930).—In mammals and fishes, the Fe content of the spleen is always greater than that of the liver, but in birds, reptiles and amphibians the opposite is true. On the other hand, the glutathione content is greater in the liver of mammals and fishes than in the spleen and vice versa for birds, reptiles and amphibians. The amt. of both Fe and glutathione in the lungs of birds is relatively higher than in the other organs. **II. Relationship of the iron content of the organs and the growth of animals.** *Ibid* 49–61. The fluctuations in the Fe content of growing honeybees and silk worms parallel the cytochrome content, gradually becoming greater during the larva stage, decreasing during the pupa stage and increasing again in the imago stage. The amt. of Fe in growing chick embryos reaches its max. somewhat later than the glutathione and cytochrome content. The Fe content per g. dry substance in the organs of normal chickens was found to be: liver 0.1806, heart 0.1317, leg muscle 0.0879, brain 0.1444, kidney 0.4920, lung 0.0525 and blood 0.1468 mg. Egg yolk contained 0.0314 mg. Fe/g. dry substance, but no Fe was found in egg white. The water content of the organs of chick embryos decreased with growth. **III. Effect of the time of year upon the iron content of animals that hibernate [toad] (Bufo vulgaris japonicus).** *Ibid* 62–70.—In general, the Fe content of the various organs of the toad is greatest in winter and least during the spawning time. The glycogen content parallels that of Fe, but the glutathione content is just the reverse. The liver always contains more than twice as much Fe as the spleen. A. WIEBEN

The carbon dioxide content of the blood in the new born. HOWARD F. KANE AND JOSEPH KREISELMAN. *Am. J. Obstet. & Gynec.* **20**, 826–7(1930).—A study of 47 specimens indicates that the CO_2 of the blood in the new born is consistently high and increases with the degree of asphyxia. R. C. WILLSON

Alkali reserve in blood during gestation. S. PASCALI. *Clinica Ostetrica* **32**, 537–55

(1930); *J. Am. Med. Assoc.* **96**, 76.—From studies of 45 cases in various months of gestation, it is concluded that in the first 3 months of pregnancy the alkali reserve is lowered, but not markedly. The normal limits of alkali reserve are maintained between the fourth and eighth months. In the ninth month the reserve is about normal but tends to fall in the beginning of labor. R. C. WILLSON

Cholesterol and bilirubin contents of blood of mother and child. H. HINGLAIS AND J. GOVAERTS. *Gynéc. et Obstét.* **22**, 137(1930); *J. Am. Med. Assoc.* **95**, 1870.—Hypercholesterolemia in the mother is frequent at term but it is by no means observed constantly. The cholesterol content of infants at birth is distinctly low. During the first few days after birth the blood cholesterol of the infant increases markedly. No relation was found to exist between the excess blood bilirubin at birth and the low cholesterol value. Bilirubinemia decreased in the first few days after birth. R. C. WILLSON

Organic and inorganic phosphorus content of blood in children. P. FEDOROV. *Vrachebnoe Delo* **13**, 505–10(1930); *J. Am. Med. Assoc.* **95**, 1789.—The results given are from examns. of 1000 samples of blood from 254 healthy children aged from 7 to 15 yrs. The av. inorg. P in blood of boys and girls was about the same, 3.97 mg. per 100 cc. Org. P was 6.02 mg. per 100 cc. No seasonal changes in org. P were observed. R. C. W.

Oxygen and carbon dioxide inhalations and their effect on circulation. C. KROETZ. *Z. Kreislaufforsch.* **22**, 641(1930); *J. Am. Med. Assoc.* **96**, 80.—In man O inhalations do not increase the catabolic processes in the organism; there is, however, a high elimination of N. The latter reaches, or nearly so, the increase in the amt. of O intake. In healthy subjects the arterial blood O remains unchanged but the amt. of O in venous blood is usually greatly increased. There is a definite increase in the min. vol. of the circulation. O inhalations in cardiacs produce an increase in the O tension of the tissue, a normalization of the O content of the arterial blood and an elevation of the low min. vol. and beat vol. in decompensation. CO_2 inhalations increase the O content of the arterial blood and increase the venous reflux and with it the min. vol. and the beat vol. R. C. WILLSON

G—PATHOLOGY

H. GIDEON WELLS

Anaphylaxis with water-soluble specific substance from yeast-like fungi. T. J. KUROTCHKIN AND C. E. LIM. *Proc. Soc. Exptl. Biol. Med.* **28**, 223–5(1930).—The sensitizing power of the mycelial growth is distinctly higher than that of the budding cell growth of the same fungus. *Monilia pinoyi* had a higher sensitizing capacity than *M. psilosis;* culturally, the former fungus differed from the latter in that its growth was accompanied by a rapid and rich formation of the mycelium. The guinea pig was used. C. V. BAILEY

Zinc and cancer. A. ZLATAROFF. *Bull. soc. chim. biol.* **12**, 44(1930).—It is suggested that accumulation of Zn is one defense of the organism against the abnormal metabolism of the cancer cell, the Zn tending to inhibit the enhanced activity of proteolytic enzymes and catalase, to stimulate the decreased activity of peroxidase and to oppose the increased colloidal activity of the cancer cell, thus tending to reëstablish normal cellular respiration. B. C. A.

Use of precipitated diphtheria toxin in the preparation of anti-diphtheria serum. P. SÉDALLIAN AND MME. CLAVEL. *Compt. rend.* **190**, 1525–6(1930).—The ppt. obtained when diphtheria toxin is adjusted to p_H 4.7 (cf. *Compt. rend. soc. biol.* **97**, 1543–5(1927); *C. A.* **22**, 810; **23**, 3509) is dissolved in a neutral peptone broth (Martin), and then injected (in increasing amts. during 3 months) into horses. The serum obtained is of the same value (as an antigen) as that resulting from injection of the original toxin. B. C. A.

Potassium content of pleural discharges. DIMITRESCU-MANTE. *Compt. rend. soc. biol.* **102**, 971–2(1929).—Av. values are 25–35 mg. per 100 cc. B. C. A.

Effect of various salts on the stability of diphtheria toxin. S. SCHMIDT. *Compt. rend. soc. biol.* **103**, 95–8, 98–100, 104–6(1930); cf. *C. A.* **24**, 5855. B. C. A.

Role of the electrolyte in the diphtheria toxin-antitoxin reaction. Coagulation of the purified toxin in presence of various salts. S. SCHMIDT. *Compt. rend. soc. biol.* **103**, 101–3, 106–8(1930); cf. *C. A.* **24**, 5855. B. C. A.

The influence of different salts on the stability of toxin and antitoxin. S. SCHMIDT. *Z. Immunität.* **66**, 506–18(1930); cf. preceding abstract.—Diphtheria antitoxin is much more stable to the destructive action of salts than is toxin. The flocculating function of both substances is less stable than the antigenic or antitoxic properties.

Salts of acids which have strong oxidizing or reducing actions quickly destroy toxin and antitoxin. This is also true for salts of certain aromatic acids, as salicylic and cinnamic acids. JULIAN H. LEWIS

Occurrence of xanthine calculi in New Zealand sheep. T. H. EASTERFIELD AND J. A. BRUCE. *New Zealand J. Sci. Tech.* 11, 357–61(1930).—Calculi found in the kidneys of certain sheep consist of xanthine. The probable cause is a deficiency of minerals in the pasturage. B. C. A.

Hypochromic anemia with achlorhydria. THEODORE R. WAUGH. *Arch. Internal Med.* 47, 71–81(1931).—Mostly clinical. J. B. BROWN

The cholesterol partition of the blood plasma in parenchymatous diseases of the liver. EMANUEL Z. EPSTEIN. *Arch. Internal Med.* 47, 82–93(1931).—The cholesterol ester values of the blood plasma in acute parenchymatous damage of the liver are diminished or reduced to zero in proportion to the severity of the disease process. The cholesterol partition is normal in atrophic cirrhosis. J. B. BROWN

Chemistry and metabolism in experimental yellow fever in Macacus rhesus monkeys. III. Blood sugar and liver glycogen. A. MAURICE WAKEMAN AND CLARE A. MORRELL. *Arch. Internal Med.* 47, 104–15(1931); cf. *C. A.* 24, 5835.—Monkeys with yellow fever showed hypoglucemia 24 hrs. before death. Hypoglucemic convulsions during fasting could not be produced even with blood sugar as low as 45 mg. %. In yellow fever, monkeys with hypoglucemia showed low liver glycogen. Adrenaline produced no hyperglucemic symptoms. J. B. BROWN

The potassium content of the hearts of persons dying from edematous and nonedematous conditions. L. C. SCOTT. *Arch. Internal Med.* 47, 116–21(1931).—There is no appreciable av. difference in the content of water, Na and K in the hearts of edematous and nonedematous persons. There is considerable individual variation. The Na content may be greater or less than K. J. B. BROWN

The blood lipoids in nephrosis and chronic nephritis with edema. L. LICHTENSTEIN AND EMANUEL Z. EPSTEIN. *Arch. Internal Med.* 47, 122–7(1931).—Increased cholesterol, both total and ester, and phosphatides were found in the blood plasma of patients with various nephroses. The lipoidemia was accompanied usually by diminution of serum proteins, especially albumin. Similar results were obtained on 7 cases of chronic glomerulonephritis. J. B. BROWN

Terminal hypoglucemia. E. G. SCHMIDT AND T. NELSON CAREY. *Arch. Internal Med.* 47, 128–34(1931).—Detn. of blood sugar in 33 nondiabetic patients dying in the hospital showed low terminal blood sugars (28–75 mg. %) in 36% of the cases. Urea usually rose just prior to death. J. B. BROWN

The optical activity of cerebrospinal fluid in suppurative meningitis, and its lactic acid, sugar and chloride content. SYDNEY L. WRIGHT, JR., ELIZABITH F. HERR AND JOHN R. PAUL. *J. Clin. Investigation* 9, 443–61(1930).—The lactic acid concn. in the cerebrospinal fluid in suppurative meningitis is decidedly abnormal and usually related to the severity of the clinical symptoms. The ultrafiltrate of this fluid is usually *l*-rotatory. The lactic acid may be present as *l*-rotatory *d*-lactates. The ratio of concn of Cl^- in the blood and spinal fluid is not altered. The sugar and lactic acid ratios are greatly altered, there being less sugar and more lactic acid. An extended bibliography is given. J. B. BROWN

The proportion of certain important inorganic constituents in the dying heart muscle. L. C. SCOTT. *J. Clin. Investigation* 9, 463–74(1930).—As a result of a large series of analyses of heart muscle from persons dying from a variety of diseases, there does not seem to be any relation between the water content, the content of ash, Ca, Mg, K and Na and disease. With the exception of Mg, the inorg. constituents are quite variable. Hearts from individuals dying from arteriosclerotic changes do not show high Ca content. A reversed ratio of K to Na may indicate an affected cardiac contractility. J. B. BROWN

The humoral origin of the paresis consecutive to the destruction of the suprarenals J. E. ABELOUS AND H. LASSALLE. *Compt. rend. soc. biol.* 103, 475–7(1930).—The injection of blood from a frog paralyzed as a result of destruction of its suprarenals into a frog whose suprarenals have been extirpated results in paralysis and death, if injection is made into a normal frog, the same disturbances result after a very short delay. They are, however, transient, the poisons being gradually destroyed or neutralized by adrenaline. The considerable increase of muscular chronaxy in relation to that of the nerve implies a curarizing action of the poisons which accumulate in the organism when its suprarenal function is suppressed. B. C. BRUNSTETTER

The protein equilibrium of blood serum in cerebral tumors. CH. ACHARD, M. BARRÉTY AND A. CODOUNIS. *Compt. rend. soc. biol.* 105, 346–7(1930).—A study of

10 cases of cerebral tumor showed that the protein equilibria of the blood sera were practically undisturbed. The range of values for total protein was 76.30–89.74 g. per 1000; for albumin, 39.10–58.84 and for globulin, 25.36–41.07 g. per 1000. The albumin–globulin ratio ranged from 0.95 to 2.12. B. C. BRUNSTETTER

Oxalaturia and increased oxalic acid secretion in urine in tuberculosis. JOSEF A. LANGER AND TH. LITTIG. *Beitr. klin. Tuberk.* 72, 492–6(1929).—Among 150 tuberculous individuals examd. there were 29.2% with a pos. oxalaturia, 48.2% with variable findings and 22.6% persistently neg. Of the latter there were about 61.7% with severe processes. Among children and youths under 16 years oxalate crystals were found less frequently. No effect of a febrile reaction was noted and a diet rich in oxalic acid was without effect. H. J. CORPER

Experimental studies on artificial immunization against tuberculosis. Hemolysin tests. P. KALLOS AND E. BAJZA. *Beitr. klin. Tuberk.* 73, 323–4(1930).—In earlier expts. on artificial tuberculosis immunization in which tuberculous tissues were placed subcutaneously in sacs impervious to bacteria (*Beitr. klin. Tuberk.* 71, 604(1929)) it was recommended that this method be used for immunizing purposes. In order to det. whether these sacs are suitable for the production of antibodies, sheep erythrocytes were placed in the sacs subcutaneously in rabbits and it was shown that the serum of these animals after a short time contained a fair titer of hemolysins. H. J. C.

Bilirubin determination in the blood serum in chronic pulmonary tuberculosis. F. WARNECKE. *Z. Tuberk.* 54, 321–7(1929).—As the result of an examn. of 134 patients with severe bilateral pulmonary tuberculosis there was found a diminution of bilirubin in the blood serum 0.002 mg. as compared to normal 0.005 mg. Toxic destruction of the liver parenchyma, of the reticulo-endothelium, insufficient supply of hemoglobin or O unsatn. of hemoglobin are looked upon as possible causes. The detns. were made by means of direct and indirect diazo reactions and with the Autenreith colorimeter. H. J. CORPER

Blood sedimentation and white blood picture in the prognosis of pulmonary tuberculosis. HERMAN VOS. *Z. Tuberk.* 55, 431–7(1930).—Study of the blood picture and sedimentation revealed a disagreement between the 2 in 22% of 369 cases examd. In the cases where disagreement occurred the majority showed a parallelism of the clinical course and the leucocyte formula while the smaller proportion revealed an agreement of the sedimentation rate and the clinical course. Conclusion: The hemogram more rapidly reacts to the immuno-biologic condition of the body than the sedimentation rate. H. J. CORPER

Studies on the tuberculin reaction. G. PLATONOV AND S. SHAVROVA. *Beitr klin. Tuberk.* 73, 435–41(1930).—In elaboration of observations made by others that certain substances possess the property of inhibiting or neutralizing the local tuberculin reaction, the authors used solns. of Na morrhuate and Na gynocardate, as well as solns. of Ca and Mn salts. After the amt. of tuberculin producing a reaction in the patient had been detd. these various reagents were added in different concns. Na morrhuate and Na gynocardate caused a definite diminution in the reaction while $MnCl_2$ increased it and $CaCl_2$ gave indefinite results. It is believed that the action of Na morrhuate and Na gynocardate is to be explained on the basis of the antitryptic properties of the unsatd. lipoids, while with $CaCl_2$ the possibility of the action through the nervous system cannot be excluded. On the basis of a parallelism between the local and general sensitiveness, it is reasoned that these expts. may point to a way of desensitizing lung tissue for therapeutic purposes. J. H. CORPER

Further observations on the serum calcium and plasma cholesterol in health and disease and on the blood chemistry in osteomalacia. T. A. HUGHES, D. L. SHRIVASTAVA, P. N. SAHAI AND K. S. MALIK. *Indian J. Med. Research* 18, 517–26(1930).—The serum Ca of residents in the Punjab is higher than that of normal inhabitants of temperate climates. The oral administration of vitamin D (Vigantol or Radiostol) or vitamin A (Radiostoleum) caused a rise of serum Ca in 4 cases of osteomalacia, but indefinite changes in serum P or plasma cholesterol. H. EAGLE

Chemical composition of urinary calculi in rats. S. RANGANATHAN. *Indian J. Med. Research.* 18, 599–613(1930).—The compn. of the urinary calculi of albino rats varies with the diet. Ca-rich stones develop on a Ca-rich diet; they contain it as $CaCO_3$, $Ca(OH)_2$ or both, are poor in P and N and contain no uric acid. $CaCO_3$ stones contain little H_2O; $Ca(OH)_2$ stones may contain as high as 49% H_2O. Mg-NH_4PO_4 stones develop on diets contg. no added lime. H. EAGLE

Chemical composition of the "nucleus" of urinary calculi. S. RANGANATHAN. *Indian J. Med. Research* 18, 613–7(1930).—The nuclei of vesical calculi are not homo-

geneous. They contain uric acid, urates and only traces of phosphates; their compns. usually, but not necessarily, parallel the compn. of the surrounding stone. H. E.

Renal diabetes and ketonuria. WILHELM BERG. *Klin. Wochschr.* **9**, 1621–3 (1930).—A description is given of an unusual case of renal diabetes, with development of ketonuria during pneumonia. H. EAGLE

Functional disturbances of the kidneys in diabetic coma. A. Wl. ELMER AND M. SCHEPS. *Klin. Wochschr.* **9**, 1631(1931).—Contrary to the conclusions of Gottschalk and Müller, ketonemia and acidosis may play a very significant part in causing kidney insufficiency in diabetic coma. Ketonuria, decreased alkali reserve and ketonemia do not necessarily run parallel. A very severe ketonemia (> 300 mg. %) is quite compatible with negligible ketonuria and a plasma CO_2 of 40%. H. EAGLE

Calcium gout and calcinosis universalis. HERMANN STEINITZ. *Klin. Wochschr.* **9**, 1632–4(1930). H. EAGLE

The metabolism of progressive muscular dystrophy. GERTRUD MOSBERG. *Klin. Wochschr.* **9**, 2051–2(1930).—In 3 cases of infantile muscular atrophy which presented no clinical signs of endocrine disturbances there was (1) an increase in blood Ca, cholesterol and lactic acid, (2) abnormal blood glucose and NaCl curves following their ingestion and (3) a normal insulin curve. H. EAGLE

Alimentary lipemia. A. HIRSCH. *Klin. Wochschr.* **9**, 2062–4(1930).—Alimentary lipemia is not observed in cases of portal obstruction (atrophic cirrhosis, ascites) or in disturbances of fat absorption of the most diverse kind (fever, cachexia, bile duct obstruction). Alimentary lipemia is therefore not a functional test of a cirrhotic liver, but of enteral fat resorption. Its absence is, however, one of the regular and early symptoms of atrophic cirrhosis. H. EAGLE

Specific skin reactions in patients with gonorrhea by means of specific protein-free substances derived from gonococci. WOLFGANG CASPER. *Klin. Wochschr* **9**, 2154–8(1930).—A protein-free, type-specific deriv. of Type I gonococcus, carbohydrate in nature, gave specific skin reactions in gonorrheic subjects, apparently allergic in nature. Type II derivs. gave no reaction with these patients; conversely, the Type I substance gave no reaction in a patient who was sensitive to Type II. H. EAGLE

Uremia in scarlatinal nephritis. A. ALTMANN. *Klin. Wochschr.* **9**, 2252–4 (1930).—The usual premonitory signs may be completely absent in cases of uremia following scarlatinal nephritis. The non-protein N may be normal; blood pressure may not be high; and there may be no oliguria, hematuria or albuminuria. A. suggests the possibility that the convulsive uremia of scarlatinal nephritis may differ in essential respects from the "quiet" uremia of chronic nephritis. H. EAGLE

Hyperinsulinismus with a hypoglucemic symptom complex. F. KRAUSE. *Klin Wochschr.* **9**, 2346–9(1930). H. EAGLE

Nephrosis and glucosuria. H. STRAUSS. *Klin. Wochschr.* **9**, 2388–9(1930) Previous communications have shown that there is a low threshold value for blood sugar in nephrosis following the peroral intake of glucose. The results of Fell, which indicate an abnormally high kidney threshold, were obtained by the intravenous injection of glucose. H. EAGLE

Percutaneous immunization with the Löwenstein diphtheria protective salve. HEINRICH BAAR AND HANS BENEDICT. *Wochschr.* **9**, 2395–6(1930).—Eighty % of 106 children became Schick neg. following percutaneous immunization. Inducing an erythema by means of a mustard plaster previous to the application of the toxoid-salve increases the absorption. H. EAGLE

Experimental basis for the serological demonstration of a specific cancer antigen. H LEHMANN-FACIUS. *Klin. Wochschr.* **9**, 2430–3(1930).—A lipoid which reacts specifically with a rabbit anti-carcinoma serum can be obtained in the acetone-insol., petr.-ether-sol. fraction of the original carcinoma tissue. This fraction does not react with Wassermann-pos. sera, and does not react with a group-specific antiserum. H. EAGLE

Humoral changes in a case of trypanosomiasis (a contribution to the question of auto-antibodies). ÖDÖN FISCHER. *Klin. Wochschr.* **9**, 2436–8(1930).—The serum of a patient with trypanosomiasis contained agglutinins at 0° for human blood cells of all groups, including his own cells, and complement-fixing antibodies against an alc ext. of human red cells. F. interprets these as antibodies to the hosts' own red cells, due to changes induced by the infection. H. EAGLE

Observations on the sugar metabolism in a case of spontaneous levulosuria. P. A. HEERES AND HERMAN VOS. *Klin. Wochschr.* **9**, 2440–1(1930). H. EAGLE

Influence of the benzene nucleus on the specificity of azoproteins. M. ADANT. *Compt. rend. soc. biol.* **103**, 539–40(1930); *Physiol. Abstracts* **15**, 260.—In the azoproteins

obtained by coupling diazotized aniline with serum protein, the protein fragment has lost its specificity. An active precipitin corresponding to the serum employed in production is quite free from activity toward the azoprotein. Replacement of the aniline mol. by a benzidine or naphthylamine mol. causes no modification of the specificity of the antibody. G. G.

Antigenic properties of gelatin. R. Bruynoghe and P. Vassiliadis. *Compt. rend. soc. biol.* **103**, 543–4(1930); *Physiol. Abstracts* **15**, 260.—Gelatin and gelatin aniline were injected into animals with the view of ascertaining whether they caused the production of deviating substances. Neither serum gave the slightest trace of deviation of alexin on gelatin coupled with aniline, but both fixed the alexin on gelatin by itself. The inactivity of the gelatin aniline serum toward the antigen cannot be attributed to a want of sensitizing substances; it is rather due to the nature of the antigen. G. G.

Antigenic properties of collagen and their modification under the influence of radium emanation. J. Loiseleur and Ach. Urbain. *Compt. rend. soc. biol.* **103**, 776–8(1930); *Physiol. Abstracts* **15**, 258–9.—The flocculation of collagen under the action of Ra is preceded by diminution of viscosity and lowering of the antigenic properties. G. G.

Experimental production of chicken sarcoma with arsenic trioxide. N. C. Laclau and C. Pillado Matheu. *Rev. soc. argentina biol.* **5**, 744–67(1929); *Physiol. Abstracts* **15**, 262.—Carrel's results could not be repeated. Injections of As_2O_3 and embryonic pulp did not produce sarcoma. Cholesterol injections did not modify these results. No results were obtained by modifying the time of contact of arsenic and embryonic pulp, varying the p_H and adding $ZnSO_4$ or ext. of rat sarcoma. Substitution of embryonic by spleen pulp also gave neg. results. Granuloma were produced by injecting clay. Subsequent injections of arsenic did not produce cancer. G. G.

Factors affecting the deposition of dental calculus. Geoffrey H. Smith. *Australian J. Exptl. Biol. Med. Sci.* **7**, 45–77(1930).—Loss of CO_2, changes in p_H value and phosphate content of the saliva are not important factors in the deposition of dental calculi. A salivary phosphatase from desquamated epithelial cells which forms inorg. phosphate from org. esters is the chief factor. The optimum p_H of the enzyme is 5.5. C. G. King

Rapid precipitation tests for syphilis and blood transfusion. B. S. Levine. *Am. J. Syphilis* **15**, 81–9(1931).—Antigen pptn. is merely the first step of the complement-fixation procedure made visible. The recent pptn. procedures used in the lab. diagnosis of syphilis are relatively not greater as improvements over the early pptn. procedures than the cold incubation complement-fixation procedures (Kolmer and similar tests) are over the early Wassermann tests. The improved pptn. procedures are not intrinsically specific for syphilis. They are empirical tests exactly as are the improved complement-fixation tests. None of the antigen pptn. procedures is any more sensitive in reaction at any stage of the syphilitic disease than are the properly standardized cold incubation complement-fixation procedures. Antigen pptn. procedures, similar to those of complement fixation, yield pos. reactions, mostly of the weaker intensity, with serum of individuals affected with certain chronic low-grade conditions other than syphilis. Antigen pptn. tests for syphilis have their zones of nonreactivity similar to the complement-fixation procedures. The colloidal conditions prevailing in some sera at times may favor complement fixation and not antigen pptn. and *vice versa*. The serum conditions which lead to nonreaction either with the pptn. or complement-fixation procedures or both are intermittent in the majority of instances. The proper precautions to be taken in testing blood sera before deciding upon their suitability for transfusion are given. B. S. Levine

Electrodialysis of antitoxin serums. Fernando Modern. *Rev. inst. bacteriol.* **5**, 695–702(1930).—An exptl. review and also original study in the electrodialysis of serum-antitoxin with a view to its possible application on a large scale to the concn. of immune serums. B. S. Levine

Purification of antidiphtheric serum by thermal coagulation in the presence of salts. Raúl Wernicke and Fernando Modern. *Rev. inst. bacteriol.* **5**, 713–7 (1930).—Heating antidiphtheric serum for 10 min. at 70° in the presence of salts destroys its antitoxic properties. Such destruction increases with the duration of the heating and with the salt concn. The liquid fraction of the serum thus obtained generally is poorer in total protein in comparison with the proteins carrying the antitoxin than is the original serum. Therefore the ratio antitoxin units:1 g. protein is between 2 and 3 times as great in this liquid fraction as in the original serum, but it never exceeds 3 times its value. The yield in the antitoxin varies and generally reaches

60%, though it may be as high as 92–95%. More of the antitoxin is recovered in the presence of $(NH_4)_2SO_4$ and Na_2SO_4 than in the presence of NaCl. B. S. LEVINE

A contribution to the study of the precipitation of diphtheria toxin-antitoxin. FERNANDO MODERN AND RAÚL WERNICKE. *Rev. inst. bacteriol.* 5, 705–12(T. A.) (1930).—Pptd. toxin-antitoxin requires a min. reaction of $p_H = 3.6$ to dissolve completely. In acid medium the pptd. T. A. liberates the antitoxin, the optimum reaction being $p_H = 3.2$ to 3.6. Temp. has an influence upon this reaction, the optimum being at 10–15°. The antitoxin unit content increases in the course of time from the instant the pptd. T. A. has gone into soln. The yield in the antitoxin units recovered from the T. A. in acid soln. increases with the diln. B. S. LEVINE

Plurality of the antigen contained in B. anthracis. A. SORDELLI AND V. DEULOFEU. *Rev. inst. bacteriol.* 5, 778–85(1930).—With the aid of water or physiol. salt soln., preferably warm, it is possible to ext. from *B. anthracis*, cultivated on serum agar, a complex possessing complement-fixing properties in the presence of that fraction of anticarbuncle serum which is sol. in H_2O and CO_2. In this ext. there is also a substance (hydrocarbon) which possesses the properties of a precipitinogenic antigen. Both substances are relatively thermostable in neutral and alk. reaction. The complement-fixing complex is destroyed by heat in acid medium. Both complexes are pptd. by alc. and acetone. The precipitinogenic substance is not thereby altered with regard to its antigenic properties, whereas the complement-fixing fraction completely loses its antigenic properties. B. S. LEVINE

Studies in allergy. I. The specific activity of pollen oil. EDGAR L. MILFORD. *J. Allergy* 1, 331–3(1930).—Oil extd. from dry ragweed pollen with the usual fat solvents produced skin reactions in only $^2/_3$ of the patients who reacted to aq. exts. of the pollen. Passively sensitized areas of the skin of normal people reacted to the aq. exts. when these sites had been exhausted by the oil ext. JULIAN H. LEWIS

Allergy considered as a special type of alkalosis. HARRY BECKMAN. *J. Allergy* 1, 496–500(1930).—Because clinical conditions assocd. with acidosis either relieve or prevent allergy B. believes that a "potential alkalosis" is an important causative factor in allergy. He emphasizes the use of nitrohydrochloric acid in the treatment of hay fever. JULIAN H. LEWIS

Studies on pollen and pollen extracts. IV. The allergically active constituent in pollen oil. MARJORIE B. MOORE, HOBART W. CROMWELL AND EDMOND E. MOORE. *J. Allergy* 2, 6–10(1931).—The non-dialyzable H_2O-free EtOH-sol. fractions of pollens have a skin-reacting activity. From the results of local passive sensitization and desensitization tests it is believed that the active constituent in pollen oil is identical with one or more of the antigens extd. by aq. solvents. Chem. tests of the active non-dialyzable constituent of pollen oil indicates that it may be glucosidic in nature. JULIAN H. LEWIS

Further studies on the precipitation test for syphilis. EMIL WEISS. *J. Infectious Diseases* 47, 355–8(1930).—The comparative study of Kahn's antigens with regard to the temp., time and ratio of tissue to solvent employed in their prepn. led to the prepn. of an improved antigen. Dry beef heart is extd. with EtOH in the ratio of 1:13 for 40 min. in the icebox. The ext. is discarded and the tissue dried. To the dried tissue 95% alc. is added in the ratio of 1:5. The alc. extn. is carried out at 37° for 3 days. This ext. is then filtered and left overnight at room temp. The ext. is refiltered and 0.6% cholesterol is added. This antigen is simpler to prep., has a wider sp. zone and does not require addnl. sensitizing or correcting. JULIAN H. LEWIS

Serologic studies on the proteins found in casein. D. C. CARPENTER AND G. J. HUCKER. *J. Infectious Diseases* 47, 435–42(1930).—By extn. with acid 70% alc. and by fractionation with K oxalate 3 proteins having mol. wts., resp., of 98,000, 188,000 and 375,000 were sepd. from crude casein. These proteins were clearly distinguishable from one another by serologic reactions. It was also found that the alc.-sol. protein of Osborne and Wakeman is not the same as the acid-alc.-sol. protein having a mol. wt. of 375,000. JULIAN H. LEWIS

Precipitation with cerebrospinal fluids. A. M. MALLOY, R. L. KAHN AND LUCY WESTALL. *J. Infectious Diseases* 48, 203–11(1931).—As is true with the Kahn reaction, the colloidal Au and mastic reactions depend on the globulin fraction of the spinal fluid, the albumin fraction giving neg. results. The globulin fraction gives results somewhat more sensitive than the unfractionated fluid, undoubtedly because of the removal of the protective action of the albumin. After a Kahn test has been performed with a soln. of globulin obtained from the spinal fluid and after removal of the ppt. by centrifugation, the supernatant soln. continues to give colloidal Au and mastic reactions, indicating that the pptn. substances in the globulin soln. (or the

conditions of this soln.) responsible for the Kahn reaction are not the same as those responsible for the colloidal Au and mastic reactions. Heating the globulin fraction at 56° up to 2 hrs. exerts little effect on the 3 reactions. When heating is prolonged to 24 hrs., there is a tendency toward reduction in sensitivity, especially in that of the Kahn reaction. Heating the globulin exerts comparatively little reduction in the sensitiveness of the colloidal Au and mastic reactions and considerable reduction in that of the Kahn reaction. After heating at 70° for 30 min., there is reduction in the sensitiveness of the 1st 2 reactions and marked reduction in that of the Kahn reaction. These heating expts. also indicate that the conditions governing the Kahn reaction are not identical with those governing the colloidal Au and mastic reactions. J. H. L.

Detoxifying and disinfecting properties of sodium salicylate. Its action on diphtheria and tetanus toxins and on streptococcal "toxic" filtrates. KONRAD BIRKHAUG. *J. Infectious Diseases* **48**, 212-25(1931).—A satd. soln. of Na salicylate has the power of neutralizing diphtheria and tetanus toxins *in vitro* without destroying their antitoxinogenic capacity. Neutralization proceeds in direct proportion to the concn. of Na salicylate, the duration of contact and the degree of temp. Simultaneous injection of pure toxin and the required amt. of Na salicylate that produces a neutral mixt. *in vitro* fails to avert death from diphtherial toxemia, although the period of survival is slightly prolonged. No neutralizing effect is exercised by the satd. soln. of Na salicylate on the toxic filtrates of hemolytic or nonhemolytic streptococci, a feature that seps. these "toxins" from the true bacterial exotoxins of *C. diphtheriae* and *Cl. tetani*. The bactericidal action of Na salicylate on commonly encountered pathogenic microorganisms is about $^1/_{10}$ that of phenol. The precise mode of action of Na salicylate *in vivo* remains obscure. Its dual capacity to exercise antitoxic and antiseptic action *in vitro* suggests the hypothetic possibility that its therapeutic success in certain infectious diseases is effected by weakening the pathogenic microörganisms and their capacity to secrete the deleterious exotoxins. JULIAN H. LEWIS

Titration of the antigenic properties of diphtheria toxin in vitro. E. HOEN AND L. TSCHERTKOW. *Z. Immunitäts.* **66**, 389–93(1930).—Flocculation tests are not adapted to the titration of antitoxin-binding values of diphtheria toxin and its derivs. but the ring pptn. test gives const. and accurate results. JULIAN H. LEWIS

The action of phenol-alcohol on serological reactions. G. SOLLAZZO. *Z. Immunitäts.* **66**, 424-42(1930).—Phenol and alc. added to lipoid antigens (sp. lipoids, Wassermann and Forssman antigens) make them more reactive in immune reactions. Phenol alone is more active than alc., but a mixt. of the 2 is most active. J. H. L.

The identity of heterogenetic antigens. K. A. FRIDEDE AND L. A. SCHWARZMANN. *Z. Immunitäts.* **66**, 454–64(1930).—Although 9 different heterogenetic antigens have been described the authors believe they are all the same antigen. Proof of this opinion is given in adsorption expts. JULIAN H. LEWIS

The presence of Forssman heterogenetic antigen in the blood corpuscles of the guinea pig. G. SOLLAZZO. *Z. Immunitäts.* **66**, 465–84(1930).- Heterogenetic antiserum and antiserum obtained by immunizing with sheep blood react specifically with alc. exts. of guinea pig red blood cells. The hemolytic amboceptor for guinea pig red cells in these sera is difficult to activate with guinea pig serum but can be activated readily with rabbit serum. Guinea pig red cells adsorb antibodies from heterogenetic antisera slowly. Repeated exposures of red cells to the antiserum must be used. These expts. prove that guinea red cells contain Forssman antigen. JULIAN H. LEWIS

The antagonistic influence of glucose in anaphylactic shock. K. M. DVOLAITZSKA-BARISHEVA AND M. S. GOLDBERG. *Z. Immunitäts.* **66**, 485–90(1930).—By perfusion expts. it is found that glucose in 5% concn. has the property of inhibiting the sp. action of antigen on the vessels of a sensitized guinea pig. This action of glucose is ascribed to the fact that glucose has the ability to prevent the change in the grade of dispersity of the colloids in muscle cells that result from the combination of antigen with antibody within the territory of the cell. JULIAN H. LEWIS

The occurrence of the Thomsen antigen in human organs. M. N. SINYUSHINA *Z. Immunitäts.* **66**, 491–5(1930).—The receptor which is developed by human erythrocytes exposed to the growth product of certain bacteria and which makes them agglutinable by all sp. agglutinating sera is not developed under the same conditions by cells of human organs. JULIAN H. LEWIS

The appearance of organ specific brain substances in ontogenesis. E. WITEBSKY AND G. SOLLAZO. *Z. Immunitäts.* **67**, 1–8(1930).—The brains of guinea pig embryos 4–6 cm. in length and of human fetuses of the 3rd to 4th months react with sp. antibrain sera. In earlier stages the brains do not react. The sp. antigen of embryonal brains is heat stable and alc. sol. which indicates it is lipoidal in nature. J. H. L.

med. scand. 71, 558–97(1929); cf. *C. A.* 24, 651.—For normal men and women the total cholesterol and total fatty acids were 0.1444 and 0.1524%, and 0.2466 and 0.3050%, resp. Both in the manic and melancholic phases of the manic-depressive psychosis there are notable changes in total cholesterol and total fatty acid of the blood, the values falling back to normal after recovery. S. MORGULIS

The brown pigment of hemochromatosis. MARTIN JACOBY. *Biochem. Z.* 230, 225–7(1931).—The liver obtained at autopsy of a case of hemochromatosis was finely cut to ext. the pigment. This was insol. in alc., ether, $(C_2H_3)_2CO$ or $CHCl_3$. Glacial acetic acid became strongly colored and the soln. was difficult to filter, but if the mixt. was boiled a colorless filtrate was obtained. Neither did the pigment pass into benzene, phenol, toluene or CCl_4. The pigment is very sol. in 0.85% NaCl. If the liver pulp previously treated with NaCl soln. is extd. with H_2O, it is possible to ppt. a brown substance by complete satn. with $(NH_4)_2SO_4$. This was washed with satd. $(NH_4)_2SO_4$, suspended in H_2O and dialyzed until the Nessler reaction became neg. The substance is then dissolved by the addn. of NaCl and on filtration a clear brown soln. is obtained. Of the 691 mg. dry residue in 100 cc. soln. 154 mg. was ash; 94 mg. N and 66 mg Fe. The relation between N and Fe is thus 4:1. S. MORGULIS

Urinary creatinine as a test of renal efficiency. A. MUIR CRAWFORD. *Lancet* 1930, II, 1177–79.—In a great variety of cases of nephritis, which are tested and described, the creatinine excretion for a 24-hr. period was detd. and would seem to be a reliable prognostic guide. F. B. SEIBERT

Nature of the chill-producing principle in antipneumococcus serum. ALBERT B. SABIN AND G. B. WALLACE. *J. Exptl. Med.* 53, 339–62(1931).—The chill principle appears to be formed only in blood which has been allowed to stand. The expts. reported do not show that the reaction is dependent on formed elements, fibrinogen or lipoids. Anticoagulants, filtration, dialysis and moderate heating are without effect in removing the principle from the soln. contg. it. By changes in the NaCl and H-ion concn. in antibody solns. an acid globulin and an alk. globulin fraction may be obtained The acid globulin fraction, whether or not phospholipin is present, contains the greater part of the chill principle and a small part of the antibody substance; the alk. globulin fraction contains the greater part of the antibody substance and a smaller part of the chill principle. The acid globulin fraction is not itself the chill principle but serves as a carrier of this, probably through an adsorptive process. C. J. WEST

Immunization with mixtures of poliomyelitis virus and aluminum hydroxide. C. P. RHOADS. *J. Exptl. Med.* 53, 399–404(1931).—See *C. A.* 25, 738. C. J. W.

Iron and copper in various tissues in acute myeloid leucemia. KENZUI KOJIMA AND SHINZO KOSAKA. *Nagoya J. Med. Sci.* 5, 71–4(1930).—K. and K. tabulate results obtained in analyzing liver, spleen, heart muscle, kidney, cerebrum and blood in myeloid leucemia. The spleen was richest in Fe and the cortex of the kidney and brain contained more Fe than the marrow. However, the liver was richest in Cu and the cerebrum cortex contained nearly 3 times as much Cu as the marrow. A. W.

Normal urine sugar in cystoscopic examinations. RUSSELL RICHARDSON. *Am. J. Med. Sci.* 180, 171–7(1930).—Normal urine sugars in specimens obtained by ureteral catheterization usually show approx. equal amts. of sugar from the 2 kidneys in the absence of any disease which damages kidney efficiency. The sugar from a badly damaged kidney is very much decreased as compared with that from a normal kidney. R. C. WILLSON

The hydrogen-ion concentration of the blood in eclampsia. H. J. STANDER AND N. J. EASTMAN. *Am. J. Obstet. & Gynec.* 20, 822–5(1930); cf. *C. A.* 24, 884.—Immediately following an eclamptic convulsion the blood p_H usually increases, often to a true acidosis. R. C. WILLSON

Studies in epilepsy. XI. The calcium content of the blood and of the spinal fluid. WM. G. LENNOX AND MARGARET B. ALLEN. *Arch. Neurol. Psychiatry* 24, 1199–1205 (1930); cf. *C. A.* 24, 5372.—Detns. were made in 77 epileptics. Av. concns. and av. spinal fluid-serum ratios were within normal limits, although there was an abnormally wide distribution of values, with a tendency toward low spinal fluid measurements In $^1/_8$ of the patients the ratio of spinal fluid to serum Ca was less than 45%. R. C. WILLSON

Acetone bodies in normal pregnancy and in the toxemias of pregnancy. H. J. STANDER AND J. F. CADDEN. *Bull. Johns Hopkins Hosp.* 47, 382–90(1930).—The total acetone bodies (free acetone, acetoacetic acid and β-hydroxybutyric acid) in the blood of normal nonpregnant women varied between 11 and 18 mg. acetone per l. blood, after correction for lactic acid, the av. being 15.8 mg. In normal pregnant women

corrected acetone bodies varied between 11 and 24 mg., with an av. of 16.6 mg. Corrected values in pregnancy with nephritis were 8.6 to 48.8 mg., and in eclampsia they averaged 50.2 mg. R. C. WILLSON

Alkalinity of the blood in eczema. B. S. BIKKENIN AND N. N. YASNITSKY. *Kazansky Meditsinsky Jurnal* 26, 703–8(1930); *J. Am. Med. Assoc.* 95, 1546.—Urine p_H was normal but that of the blood was found to be from 0.1 to 0.5 above the av. R. C. WILLSON

Acid-base equilibrium in diseases of the heart and kidneys. I. M. LIPETS AND M. M. PISMAREV. *Kazansky Meditsinsky Jurnal* 26, 778–86(1930); *J. Am. Med. Assoc.* 95, 1629.—A decrease in the alkali reserve and a parallel decrease in the alveolar CO_2 were observed during the decompensation period in both heart and kidney diseases, usually more pronounced in the latter and in proportion to the severity of the condition. The Cl content of the urine remained unchanged. The blood urea was increased in almost all patients with kidney diseases, but in only a few patients with cardiac complaints. R. C. WILLSON

Peculiarities of glucemic reaction in early infancy. V. L. STYRIKOVICH. *Okhrany Materinstva i Detstva* 1, 28–42(1929); *J. Am. Med. Assoc.* 95, 1789(1930).—S. studied the various phases of the glucemic reaction and recognized the following main types and subtypes, according to the curves they give: (1) with a single rise, encountered in only 37% of cases; (*a*) to a considerable height with a more or less rapid descent to normal; (*b*) to a moderate height, remaining there for a time (1 hr. or longer), with sometimes a wave-like fluctuation, and thereupon dropping—in some cases with a tardy hypoglucemia; (*c*) to a modest height with subsequent drop to a lower level on an empty stomach; (2) with 2 rises: (*a*) with the second rise lower than the first; and the second wave of smaller vol. than the first; (*b*) with the second rise attaining or surpassing the level of the first, and the second wave equal to or exceeding the first; (*c*) with the second rise rapid, returning to normal after a short time; (3) with 3 rises—a rare form. R. C. WILLSON

Absorption of calcium and phosphorus in experimental rickets. F. PEOLA AND G. GUASSARDO. *Riv. clin. pediatrica* 28, 583(1930); *J. Am. Med. Assoc.* 95, 1541.—Normally the absorption of Ca is from 50 to 60% of the amt. taken in and that of P from 70 to 80%. In exptl. rickets that of Ca remains normal while that of P falls to 60%. This decrease appears later in the disease, however. R. C. WILLSON

Benzene derivatives of intestinal purtefaction in the etiology of cancer. E. GRANDJEAN. *Schweiz. med. Wochschr.* 60, 823–8(1930); *J. Am. Med. Assoc.* 95, 1540.—Benzene derivs. of intestinal putrefaction resulting from diets rich in animal proteins exert a continuous growth stimulation on the healthy cells, and gradually the constantly irritated tissues develop into malignant tumors. Benzene derivs. are also formed wherever in suppurative processes disintegration of protein by anaerobic bacteria takes place, as in the lungs, female genitalia, abscesses of the teeth and ulcers The theory that benzene derivs. are significant in the etiology of cancer is supported by the fact that occupational cancers are most frequent in workers who come into contact with benzene and coal-tar products. R. C. WILLSON

Cardiac insufficiency; chemical changes in the blood. E. BECHER. *Z. Kreislaufforsch.* 22, 638–40(1930); *J. Am. Med. Assoc.* 96, 80.—The amino-N content of the blood in cardiac insufficiency is almost constant and varies only slightly from the normal. Occasionally the creatinine content is increased. The blood serum does not contain an increased amt. of urochrome or urochromogen. The uric acid, urea and residual N are frequently increased but not so much as in renal insufficiency. There is no increase in the aromatic substances. Phenol, cresol and its derivs. and indican are not increased. R. C. WILLSON

H—PHARMACOLOGY

A. N. RICHARDS

Effect of some imidazoles on gastric secretion. J. P. BURGERS AND A. C. IVY. *Proc. Soc. Exptl. Biol. Med.* 28, 115–6(1930).—Imidazole, imidazolepropionic acid, imidazolealdehyde, 1-imidazolelactic acid and imidazoleacrylic acid in doses of 1 mg. to 5 mg. have no effect on gastric secretion or on blood pressure in the dog. C. V. BAILEY

Effect of calcium chloride injections on blood sugar of normal and jaundiced dogs. ALLAN G. REWBRIDGE AND EDMUND ANDREWS. *Proc. Soc. Exptl. Biol. Med.* 28, 126–7(1930).—The intravenous injection of a 10% soln. of $CaCl_2$ caused a rise in blood sugar nearly as marked as that following the injection of sugar itself and tended to last

longer. Sugar and Ca seem to have a reciprocal influence on each other and one cannot say which is of greater importance in the control of blood coagulability. C. V. B.

Rate of urinary arsenic excretion after giving acetarsone ("stovarsol") and "carbarsone" by mouth. MEI-YU CHEN, H. H. ANDERSON AND C. D. LEAKE. *Proc. Soc. Exptl. Biol. Med.* **28**, 145–8(1930).—Acetarsone (3-acetylamino-4-hydroxyphenylarsonic acid) and carbarsone (4-carbaminophenylarsonic acid) are slowly excreted in the urine after oral administration. A normal man give 0.5 g. of acetarsone excreted 20% of the ingested As in 72 hrs.; given a similar dose of carbarsone he excreted 8% in 52 hrs. Another subject excreted 7% of the As in 24 hrs. following 0.5 g. of acetarsone and 13% in 42 hrs. following the ingestion of 0.5 g. of carbarsone. C. V. B.

The pharmacology of inflammation. I. Technic. LOUIS HIRSCHHORN AND M. G. MULINOS. *Proc. Soc. Exptl. Biol. Med.* **28**, 168–70(1930).—One drop of a 15% soln. of essential oil of mustard in mineral oil, instilled into the conjunctival sac of the rabbit, induces blepharospasm for 1 hr., lacrimation for 0.25 hr., immediate injection of the conjunctival blood vessels lasting for 48 hrs., pin point miosis which passes off in 1 hr. and edema which is max. in 0.5 hr. Complete recovery usually occurs in 7–14 days. The method lends itself to studies of the inhibitory and curative effects of drugs on inflammatory processes. C. V. BAILEY

Further investigations concerning the stimulating effect of anterior pituitary gland preparations on the thyroid gland. LEO LOEB, R. B. BASSETT AND HILDA FRIEDMAN. *Proc. Soc. Exptl. Biol. Med.* **28**, 209–13(1930).—Guinea pigs were injected daily with 1 cc. of an acid ext. of anterior pituitary gland for 5 consecutive days. On the 6th day the thyroid gland was markedly hypertrophied, the cells were mitotic and the colloid had largely disappeared Retrogression progressed regularly and the gland had a normal appearance at the end of 31 days. The administration of thyroid substance diminished but did not prevent this hypertrophy. The injection of anterior pituitary ext. is more potent in producing hypertrophy of the thyroid gland than is the removal of a great part of the gland or the administration of stimulating doses of KI. C. V BAILEY

Comparison of physiological action of aspidospermine and quebrachine. RAYMOND-HAMET. *Compt. rend.* **191**, 157–9(1930).—The hydrochlorides of these alkaloids isolated from the bark of *Aspidosperma quebracho blanco*, contrary to reported expts., act differently on the sympathetic or vagus nervous systems. B. C. A.

Secretion of dextrose under the influence of phosphates and sulfates. J. VAN DE VELDE. *Compt. rend. soc. biol.* **102**, 596–9(1929).—Injection of a soln. of NaH_2PO_4 into a dog after injection of dextrose accelerates the secretion of sugar in the urine, the blood corpuscles giving up more sugar than the plasma. Na_2HPO_4 has practically no effect on the p_H of the blood, but, as in the former case, the sugar is quickly secreted Na_3PO_4 produces such rapid secretion that the sugar content of the corpuscles falls temporarily below the normal. Na_2SO_4 causes marked alky. but leaves the secretion of sugar practically unchanged. B. C. A.

Sugar metabolism and water regulation. II. Treatment of cardiac diabetes with insulin and dextrose. H. TATERKA. *Klin Wochschr.* **8**, 1763–4(1929); cf. *C. A.* **24**, 4808. The action of injected insulin is retarded but more marked; dextrose causes a less rapid and less marked rise in blood sugar. Non-cardiac diabetics with insulin edema behave similarly. B. C. A.

Action of substances of the pilocarpine group (pilocarpine, arecoline, physostigmine) on the gas content of the blood. A. M. PREOBRAZHENSKII. *Russian J. Physiol.* **13**, 19–32(1930).—Expts. on dogs show that all substances of the pilocarpine group diminish greatly the O content of venous blood and leave unchanged or increase slightly that of arterial blood; decrease of the latter is, however, caused by large doses of physostigmine. If the decrease of the amt. of O in venous, with normal content in arterial, blood is the result of increased O absorption by the tissues, and diminution of the O content of arterial blood the result of insufficient arterialization of the blood in the lungs, the increased consumption of O must be a characteristic common to all substances of the group. The arterialization of the blood in the lungs thus compensates for the O consumed, except that, in most of the cases in which physostigmine and all in which toxic doses of the other substances were administered, the O content of the arterial blood falls. B. C. A.

The comparative changes in gastric acidity and urinary reaction after the injection of histamine. MILTON J. MATZNER AND IRVING GRAY. *Arch. Internal Med.* **47**, 202–5(1931).—In tests combining gastric analysis with histamine as a stimulant and estn. of urinary acidity, not over 50% of the cases showing gastric-free HCl gave a definite alk. tide. The use of histamine is discouraged. J. B. BROWN

Liver extract, liver ash and iron in the treatment of anemia. CHESTER S. KEEFER, K. K. HUANG AND C. S. YANG. *J. Clin. Investigation* 9, 533–54(1930); cf. *C. A.* **24**, 3038.—With liver ext. increased hemoglobin regeneration was shown in the nutritional anemia of childhood and in the anemias of dysentery, hookworm and pregnancy. In some cases the effect of the ext. was increased by Fe. Liver ash, equiv. to 300 g. of liver per day, was of little effect. Fe in the form of $FeCO_3$ was quite effective, usually in proportion to the size of the dose. Often the effect of Fe was greater than that of liver ext. or ash. J. B. BROWN

Cardiac antagonism of pilocarpine and tropine. RAYMOND-HAMET. *Compt. rend.* **192**, 111–3(1931).—Ordinarily the injection of tropine in a dog subjected to the action of a large dose of pilocarpine suppresses the cardiac inhibition. Since the same phenomenon is observed if sparteine replaces the tropine, it is not due to the atropine action of tropine. RACHEL BROWN

Influence of hydrogen-ion concentration on the fixation, by adsorption, of cocaine hydrochloride on the nerve fibers. JEAN RÉGNIER AND GUILLAUME VALETTE. *Compt. rend.* **192**, 114–6(1931); cf. *C. A.* **25**, 143.—The adsorption of cocaine-HCl on animal charcoal increases from p_H 3 to p_H 7.5 by 1.5 times, the increase being very marked above p_H 6. With nerve fibers the increase from p_H 3 to p_H 7.6 is 5 times. Therefore an alk. medium favors the fixation of the anesthetic on the nerve itself. R. B.

Regulation of respiration. NATHAN B. EDDY. *Quart. J. Exptl. Physiol.* **20**, 313–31(1930); cf. *C. A.* **23**, 4251.—The *effect upon salivary secretion of the intravenous administration of $NaHCO_3$, NaOH, NaCl and Na_2SO_4.* In the dog, salivary secretion elicited by continuous administration of pilocarpine is decreased by intravenous injection of $NaHCO_3$, Na_2CO_3 or NaOH. The effect produced by $NaHCO_3$ is proportional to the size of the dose, whether in isotonic or hypertonic soln. NaOH has a greater action than Na_2CO_3. $NaHCO_3$ prevents almost completely the augmenting effect upon salivary secretion of a 10-min. period of rebreathing. These alk. agents also increase submaxillary blood-vol. flow. Their effect may be due to changes in acid-base equil. in which the H-ion concn. of the interior of the cell may be a major factor. In isotonic soln. NaCl or Na_2SO_4 increases submaxillary secretion and blood-vol. flow. In hypertonic soln. they decrease the former but increase more markedly the latter. The effect of these salts seems to be due to the increase in blood-vol. flow and to the withdrawal of water from the tissues. *The effect upon salivary secretion of the intravenous administration of lactic acid, sodium lactate and HCl.* The secretion of the submaxillary gland is increased by the intravenous administration of lactic acid and HCl. The increase due to HCl is frequently followed by a decrease below normal. The effect of HCl is the same whether the sympathetic supply to the gland is intact or not. Lactic acid and HCl increase the submaxillary blood-vol. flow. The increase in secretion produced by lactic acid is greater if the vago-sympathetic has been cut. Na lactate decreases salivary secretion if the vago-sympathetic is intact, but increases it if the nerve is cut. It increases submaxillary blood-vol. flow. The lactate ion appears to be inhibitory to the central and augmentory to the peripheral mechanism of secretion. Changes in the acid-base equil. of the tissues and blood are an important factor in the effect of lactic acid, HCl and Na lactate upon secretion. Coincident changes in blood-vol. flow probably affect the results, and some additional effect of the lactate ions, such as their use as food material supplying energy for secretion, may be involved. *Effect upon salivary secretion of the intravenous administration of NH_4Cl and $(NH_4)_2CO_3$.* The administration of NH_4Cl and $(NH_4)_2CO_3$ produces an initial increase and subsequent decrease in the rate of salivary secretion and in the submaxillary blood-vol. flow. One cc. per kg. of *M*/6 NH_4Cl or $(NH_4)_2CO_3$ produces transient fall in blood pressure and brief increase in pulmonary ventilation. Five cc. per kg. of $(NH_4)_2CO_3$ lowers the blood pressure and depresses pulmonary ventilation. The effects of NH_4Cl and $(NH_4)_2CO_3$ on the salivary secretion are probably due to changes in the acid-base equil. and to changes in blood-vol. flow. RACHEL BROWN

The therapy and the prevention of carbon disulfide poisoning. G. B. AUDO-GIANOTTI. *Industria chimica* **5**, 1375–80(1930).—A summary of the symptoms, therapy and prevention of industrial poisoning by CS_2. A. W. CONTIERI

Experimental studies in the neutralizing action of sodium thiosulfate in atoxyl intoxication. N. KURODA. *Acta dermat.* **13**, 289–99. See *C. A.* **24**, 1431. E. J. C.

Sensitization of the skin of guinea pigs to phenylhydrazine. W. JADASSOHN. *Klin. Wochschr.* **9**, 551(1930). E. J. C.

The effect of insulin upon the rate of dialysis of diabetic blood sugar. ISREAL S. KLEINER, HAROLD BIRNKRANT AND THEODORE ROTHMAN. *Endocrinology* **14**, 226–8 (1930).—The addn. of dry potent insulin to hirudinized blood of a diabetic dog did not

alter the rate of dialysis of sugar from it. This indicates that the pancreatic hormone does not exert its effect by producing a more readily diffusible form of glucose.
H. J. Deuel, Jr.

Antagonism between sulfur and adrenaline. Dòmenico Campanacci. *Wiener klin. Wochschr.* 44, 79–81(1931).—The antagonistic effect on blood pressure is produced when 30 mg. of colloidal S and 1 mg. of adrenaline are injected. D. B. Dill

Assimilation of intravenously injected hexoses; phosphorus and water metabolism. E. Owsiany and M. Wierzuchowski. *Compt. rend. sac. biol.* 103, 416–8(1930); *Physiol. Abstracts* 15, 240–1.—The sugar assimilated is estd. as the difference between the amt. injected and the amt. eliminated by the kidney. Of 4 dogs, 2 assimilated glucose best and 2 fructose, 90% of the total in each case. Insulin causes an insignificant increase in glucose assimilation and has no effect on that of fructose. The amt. of inorg. P in blood and urine is lowered during the active assimilation period. The curve of P reduction is not affected by the rate of assimilation. The P curve is raised again after cessation of injection, and the rise is not prevented by insulin. G. G.

Liver and muscle glycogen and blood sugar in starved and phlorhizinized dogs. F. Rathery, R. Kourilsky and Mlle. Y. Laurent. *Compt. rend. soc. biol.* 103, 472–4(1930); *Physiol. Abstracts* 15, 240.—Starvation alone, even when prolonged, causes only a slight diminution of hepatic and muscular glycogen. Injection of phlorhizin after a period of starvation causes a diminution of hepatic and muscular glycogen. In spite of the almost complete absence of hepatic and muscular glycogen, the glucemic level may remain normal, although accompanied by a marked glucosuria. The glycogen of the liver or muscles does not seem to be essential for the maintenance of this normal level. G. G.

Influence of insulin on early variations of hepatic and muscular glycogen in the normal and phlorhizinized dog. F. Rathery, R. Kourilsky and Mlle. S. Gibert. *Compt. rend. soc. biol.* 103, 474–5(1930); *Physiol. Abstracts* 15, 240.—Phlorhizin in the fasting dog causes marked diminution of hepatic and muscular glycogen. Injection of insulin now causes rapid restoration of the glycogen of the liver, while that of muscle is still further diminished. The loss of hepatic glycogen is great, and not proportional to the muscular loss. G. G.

Chemical modifications of blood after injection of ionium nitrate. Y. Pourbaix. *Compt. rend. soc. biol.* 103, 536–8(1930); *Physiol. Abstracts* 15, 257.—Ionium injected in small doses, which are well tolerated over long periods, causes a disturbance of glucose and cholesterol metabolism manifested by instability of these substances in the blood. Later anemia sets in and is accompanied by a considerable diminution of plasma globulin and an increase of the albumin/globulin quotient. G. G.

Action of choline and its derivatives on respiration. M. Villaret. *Compt. rend. soc. biol.* 103, 675–7(1930); *Physiol. Abstracts* 15, 226.—Choline, acetylcholine and formylcholine, which have similar cardiovascular actions, also produce the same effect on the respiratory rhythm. Bromocholine causes more sustained apnea than the others, because it persists longer in the circulation. The effect is due to the choline group. G. G.

Choline apnea and artificial respiration. M. Villaret. *Compt. rend. soc. biol.* 103, 677–9(1930); *Physiol. Abstracts* 15, 226.—Choline and its derivs. cause apnea in large doses, polypnea in small doses. The effect is independent of vagus influence. The duration of the apnea is proportional to the dose. Artificial respiration saves the lives of animals treated by otherwise fatal doses. It must be continued much longer with bromocholine than with other derivs. The fatal action of the poisons is effected, not directly on the heart, but on the respiratory center. G. G.

Adrenaline, atropine and lobeline in choline apnea. M. Villaret. *Compt. rend. soc. biol.* 103, 771–2(1930); *Physiol. Abstracts* 15, 226–7.—When apnea is set up by the action of choline, it is not modified by doses of adrenaline, atropine or lobeline, which are capable of counteracting the cardiac influence of choline and its derivs. G. G.

Derivatives of choline mechanism of polypnea caused by intravenous injection of choline and its derivatives. M. Villaret. *Compt. rend. soc. biol.* 103, 772–3 (1930); *Physiol. Abstracts* 15, 227.—The polypnea elicited by the injection of choline and its derivs. into the circulation is enhanced by a discharge of adrenaline. The results correspond with the observation that in reflux or central polypnea injection of adrenaline causes, not apnea, but hyperpolypnea. G. G.

Fatty bodies in cells of the liver, lung, kidney, suprarenal and testicle in the normal dog and in the dog poisoned by tolylenediamine. J. Slotwinski. *Compt. rend soc. biol.* 103, 811–5(1930); *Physiol. Abstracts* 15, 244.—In the normal dog there is a

subpleural chain of cellular elements contg. large amts. of cholesterol esters. This reserve seems to be of great importance in defence against intoxication. Intoxication with tolylenediamine leads to infiltration of the liver cells with fat. After poisoning, the disappearance of the subpleural cells and the diminution of fatty bodies in the suprarenal cortex and in the interstitial cells of the testis indicate a defensive process and a neutralization of the toxic substances. G. G.

Histochemical and biological studies of electric ionotherapy. F. RASZEJA. *Compt. rend. soc. biol.* **103**, 799–803(1930); *Physiol. Abstracts* **15**, 213–4.—Normally in the skin of the rabbit Ca is distributed in the subcutaneous tissue and K in the epidermis. When $CaCl_2$ is ionized on a pad with the passage of an elec. current through it to the skin, the K is pushed into the deeper regions and the Ca ions occupy the surface. Rabbits treated in this way are much less susceptible than controls to the decalcifying effects of Ca-free diet. The cond. of the serum is markedly increased after introduction of Li in the above manner, and this when the urine becomes free from Li. The elimination of this element lasts longer than is revealed by the urine. G. G.

The role of the reticulo-endothelial system in the metabolism of fat in the normal dog and in the dog poisoned by tolylenediamine. J. SLOTWINSKI. *Compt. rend. soc. biol.* **103**, 816–8(1930); *Physiol. Abstracts* **15**, 244.—The reticulo-endothelial system in the tonsils, liver and bone marrow plays a most important part in the metabolism of fat. It is still more important in pathol. conditions like tolylenediamine intoxication. The fatty inclusions in the cells of the system are formed of lipoids and cholesterol esters. The elements contg. these particles in the tonsil are situated deeply in the lymphatic nodules. They are rare under the epithelium. G. G.

Pathology of aniline poisoning. G. AIELLO. *Med. Travail* **1**, 294–6(1930).—*Bull. Hyg.* **5**, 929.—A. describes the symptoms of acute and chronic poisoning by aniline dyes. Venesection and inhalation of ammonia relieved these symptoms. In most cases of dye poisoning the dye can be detected in the urine, particularly if aniline blue or black is the cause. GEORGE R. GREENBANK

Injury to the digestive tract by copying pencils. I. ILKOFF. *Deut. med. Wochschr.* **56**, 1132–3(1930); *Bull. Hyg.* **5**, 929.—The injury is due to tissue necrosis by gradual soln of the aniline violet. In a test case a man ate meat contg. a 3-cm. piece of the pencil; ulcers formed in the pylorus. Food contg. crushed pieces of the pencil was given to dogs. All the dogs showed gastric or duodenal inflammation and ulcers formed in a few days. This is due to the fact that the aniline deriv. has an alk. reaction which dissolves the albumin and thus causes destructive penetration whereas acid dyes cause coagulation and hinder penetration. GEORGE R. GREENBANK

Insulin and glycogen. I. Study in the normal dog. F. RATHERY AND R. KOURILSKY. *Ann. physiol. physiochim. biol.* **6**, 32–72(1930).—In the dog the hepatic vein contains the most glucose, the portal vein least and peripheral vessels have intermediate quantities. Following the administration of insulin, the relative order does not change, but the difference between the hepatic and peripheral veins increases. The liver therefore continues to discharge glucose into the circulation; nor can one postulate an increased avidity of the tissues for glucose, as the difference between the arterial and venous blood sugar does not increase. Immediately following the injection of insulin, the blood sugar shows a transitory increase, particularly in the hepatic vein; the liver glycogen decreases, while the muscle glycogen is not appreciably changed. Conclusions are given in the following paper. **II. Study in the dog following pancreatectomy, starvation or phlorhizin. General conclusions concerning the role of glycogen.** *Ibid* 73–128.—Following pancreatectomy, all the sugar values rise, but their order changes. The sugar of the hepatic vein falls below that of the peripheral veins; however, it remains higher than the portal blood sugar. Liver glycogen falls precipitously, while the muscle glycogen is only slightly affected. Qualitatively, the effects of insulin are exactly the same as in the normal animal, except for the fact that it induces an increase in liver glycogen. Moreover, insulin has the same effect upon starved dogs as upon normal dogs. Phlorhizin administered to fasting dogs causes an almost complete disappearance of liver glycogen, but the blood sugar remains normal. Conclusion: Liver glycogen plays no role in the maintenance of blood sugar; there is some intermediate product of metabolism in the liver. Insulin does not mobilize glycogen or activate the muscle metabolism of sugar. The effect of insulin upon glycogen, whether hepatic or muscular, is of only secondary importance in insulin hypoglucemia. Glycogen is not indispensable either for the proper functioning of the liver and muscles or for sugar metabolism. H. EAGLE

Behavior of soaps in the animal organism. IRVINE H. PAGE AND E. V. ALLEN. *Arch. Exptl. Path. Pharmakol.* **152**, 1–27(1930).—Most soaps, particularly those of

hydroxy and unsatd. acids, are highly toxic. Injected intraperitoneally into rats and mice, they cause marked histological changes, chiefly perivascular infiltration and focal degeneration in the liver and proliferative changes and adhesions in the peritoneal cavity. The total fat content of the liver decreases, but the I no. increases. On intravenous injection of soap, the blood pressure falls and respiration increases. Diethanolamine ricinoleate increases the permeability of the blood-spinal fluid barrier for circulating dyes. H. EAGLE

The action of a sympathomimetic alkaloid in Sida cordifolia (Brela). R. N. CHOPRA AND PREMANKUR DE. *Indian J. Med. Research* **18**, 467–75(1930).—The active principle of *Sida cordifolia* (Brela) is a sympathomimetic alkaloid resembling ephedrine in its pharmacol. properties. H. EAGLE

The conditions of "basic narcosis" in combined narcosis experiments. L. LENDLE. *Klin. Wochschr.* **9**, 1609–15(1930). H. EAGLE

Secondary ultra-violet radiation and its biological effect. MONA SPIEGEL-ADOLF. *Klin. Wochschr.* **9**, 1615–8(1930).—Only a small portion of the radiation-energy emmitted by Ra or x-rays is absorbed by proteins in soln., while ultra-violet light is comparatively much better utilized. The fluorescent light emitted by salt crystals following exposure to radium or x-rays is much more effective in causing the coagulation of protein, the hemolysis of red cells and the death of paramecia than the original radiation energy used to induce this fluorescence. H. EAGLE

The effect of thyroxine. O. EICHLER AND R. SANDERS. *Klin. Wochschr.* **9**, 1618(1930).—The intravenous injection of thyroxine (1.8 mg. per kg.) into rabbits causes a significant increase of the blood lactic acid and O_2 consumption. H. E.

The antagonism between adrenaline and insulin. Experiments in adrenalectomized dogs. R. CARIO. *Klin. Wochschr.* **9**, 1623–4(1930).—The injection of concd. glucose solns. into the pancreatico-duodenal artery of dogs does not cause an elevation of blood sugar, even after the adrenals have been removed. Injected into any other artery, it causes a transient hyperglucemia. This is further evidence that the blood sugar as such is an adequate hormone for the regulation of insulin secretion. Adrenaline and insulin may be antagonists in the regulation of blood sugar. H. EAGLE

Animal and clinical studies on the question of synthalin-B. HERBERT HIRSCH-KAUFMANN. *Klin. Wochschr.* **9**, 1631–2(1930). H. EAGLE

Oral desensitization of dermatoses due to alimentary idiosyncrasies by the use of species-specific peptones. ERICH URBACH. *Klin. Wochschr.* **9**, 2046–9(1930). H. EAGLE

The opposing effects of liver and spleen. A contribution to the spleen treatment of erythremia. F. HÖGLER. *Klin. Wochschr.* **9**, 2052–8(1930).—Ra irradiation of the long bones has a beneficial effect in erythremia, in which it is often followed by an excretion of aldehyde in the urine; but no beneficial effect could be discerned upon pernicious anemia. In 2 cases of erythremia a striking improvement in the blood picture was effected by the daily ingestion of large quantities of spleen over a period of months. In one case of pernicious anemia, splenectomy followed by liver therapy caused a typical erythremia, which was controlled by the subsequent administration of spleen. The liver and spleen therefore have antagonistic effects upon the erythrocytes. H. EAGLE

The separation of mixtures of dyes by normal and poisoned kidneys. RUDOLF HÖBER. *Klin. Wochschr.* **9**, 2065(1930); cf. *C. A.* **24**, 4543.—Most dyes are excreted slowly through the glomeruli (*e. g.*, cyanol) but some, like phenol red, are rapidly excreted by the tubules in a concd. form. If a mixt. is injected into frogs or rabbits, the tubular dye predominates at first; after it has been almost completely excreted, the urine contains only the glomerular dye. If the tubules are injured, as by uranium nitrate, the quick tubular excretion of a concd. dye is not observed, and one obtains only the glomerular excretion of the two in approx. the same concn. This fact suggests a method for testing tubular function in man. H. EAGLE

A highly active liver extract which can be injected. M. GÄNSSLEN. *Klin Wochschr.* 9 2099–103(1930).—Excellent results were obtained in the treatment of pernicious anemia by the intragluteal injection of protein-free liver ext. Improvement is usually obtained in 6–8 weeks. H. EAGLE

Clinical observations on the treatment of anemias with stomach preparations. FERDINAND BERTRAM. *Klin. Wochschr.* **9**, 2103–6(1930).—Using the proprietary prepn. Stomopson, B. found improvement in 10 of 11 cases of Biermer's (pernicious) anemia. In the unsuccessful case liver therapy was effective. H. EAGLE

Experimental studies on the effect of the inspiration of small quantities of benzine and benzene upon the respiratory organs and the entire body. M. SCHMIDTMANN.

Klin. Wochschr. 9, 2106–8(1930).—The inhalation by rabbits, guinea pigs, mice and rats, of small quantities of benzine or benzene-gasoline vapor over long periods of time eventually causes emphysema, chronic bronchitis, and atalectatic pneumonia. An initial leucocytosis is followed in the later stages by a marked leucopenia, and a fall in both the red cell count and hemoglobin. In the spleen, an initial myeloid infiltration of the pulp is followed by a gradual decrease in cells, pronounced phagocytosis of red cells, and, in some cases, hyalinization. These results are exactly the same as the acute changes induced by the subcutaneous injection of benzine, differing only in the long time required for their evolution (months). Heart and liver both show focal necrosis in the center of small areas of infiltration. The cumulative toxic effect of these repeated small inhalations are highly significant in the light of the continuous exposure of an urban population to the exhaust of automobile engines. H. EAGLE

The effect of beef adrenal extract upon the uterus. ERICH ENGELHART. *Klin. Wochschr.* 9, 2114–5(1930).—The subcutaneous injection of beef adrenal ext. into virginal female rabbits causes proliferative changes in both the mucosa and musculature. H. EAGLE

The decrease of oxidation processes during ether anesthesia. H. FUSS AND E. DERRA. *Klin. Wochschr.* 9, 2115–6(1930).—In dogs ether drop anesthesia causes a definite arterial O_2-unsatn., which is less pronounced with ether-air anesthesia, and not observed if an ether-O_2 mixt. is used. The increase in blood lactic acid during anesthesia bears some relation to the degree of arterial O_2-unsatn. and is possibly due to an inhibition of resynthesis. H. EAGLE

Copper treatment of anemia in nurslings. E. SCHIFF, H. ELIASBERG AND N. JOFFE. *Klin. Wochschr.* 9, 2144–5(1930).—The authors believe that the daily administration of 20 drops of 1% $CuSO_4$ $5H_2O$ is of benefit in anemia. H. EAGLE

The treatment of pernicious anemia with preparations of gastric mucosa. N. HENNING AND G. STIEGER. *Klin. Wochschr.* 9, 2145–7(1930).—A dried prepn. of pig mucosa was found to be highly effective. Acid alc. exts. were not effective. Both the antrum and fundus contain the active principle, which is not pepsin. H. EAGLE

A case of hydrazoic acid poisoning. ZD. KÖCHER. *Klin. Wochschr.* 9, 2160–1 (1930). H. EAGLE

The effect of intracutaneous injection upon the basal metabolism. WILFRIED LOWENSTEIN. *Klin. Wochschr.* 9, 2255–6(1930).—The intracutaneous injection of solns. of protein, or even H_2O, causes a marked fall in the basal metabolic rate, amounting to as much as 50%, and beginning within 10–15 min. L. suggests that it is due either to a reflex in the vegetative nervous system, or to the release of histamine from cells at the site of injection. H. EAGLE

The significance of ammonium chloride medication in the treatment of diuresis. PAUL SAXL AND OTTO ERLSBACHER. *Klin. Wochschr.* 9, 2302–3(1930).—NH_4Cl causes a lowered alkali reserve and decreased circulatory blood vol., while Salyrgan causes an increased blood vol. Despite their antagonistic action upon the vol. of circulating blood, a combination therapy with these 2 drugs causes a much more rapid removal of transudates due to cardiac failure, hepatic cirrhosis, nephritis, etc., and even of exudates, as in articular arthritis. H. EAGLE

The dependence of gas exchange and the action of iodine upon the hydrogen-ion concentration. L. WISLICKI. *Klin. Wochschr.* 9, 2354–5(1930).—Increased [$NaHCO_3$] or decreased CO_2 tension causes an increased O_2 consumption by rat muscle *in vitro*, and an increased respiratory quotient. An acid reaction has the opposite effect. NaI, in small concn., neutralizes either change; in higher concn., it causes an increased formation of lactic acid without any further effect upon O_2 consumption. It is interesting to note that it has no constant effect at serum reaction (p_H 7.46). Thyroxine has no effect, probably due to its insolubility at this H-ion concn. H. EAGLE

Excretion and storage of neodorm. ANNELIESE ROTHMAN. *Klin. Wochschr.* 9, 2398–9(1930).—Weeks after the ingestion of neodorm (bromoisopropylbutyramide) Br_2 can be demonstrated in the tissues, the brain in particular, in a water-sol. form. The Br_2 is gradually excreted, chiefly in the urine and bile. H. EAGLE

Pharmacological study of the effect of caffeine-adenine mixtures. DAVID I. MACHT AND HERMANN SCHROEDER. *Klin. Wochschr.* 9, 2429–30(1930). H. EAGLE

Treatment of insulin lipodystrophy. REINHOLD BOLLER. *Klin. Wochschr.* 9, 2433–5(1930).—The addn. of cocaine or novocaine in insulin has a preventive and therapeutic effect in diabetics who tend to develop lipodystrophy as a complication of the insulin treatment. H. EAGLE

The effect of digitalis upon the final wave of the electrocardiogram. ERNST BLUMENFELDT AND SPENCER G. STRAUSS. *Klin. Wochschr.* 9, 2439(1930).—The

reversal of the T-wave in the electrocardiogram is only an exceptional occurrence in patients receiving digitalis and cannot be taken as a criterion of digitalis effect. H. EAGLE

The effect of vasopressin and oxytocin upon the blood sugar in human beings. A. WL. ELMER AND M. SCHEPS. *Klin. Wochschr.* 9, 2439–40(1930).—Vasopressin, injected subcutaneously, usually causes an elevation in blood sugar. The effect of pituitrin is much less frequent and less marked. Oxytocin is ineffective. H. EAGLE

Local anesthetics. Derivatives of amino alcohols having the function of primary alcohols. E. FOURNEAU, G. BENOIT AND ROGER FIRMENICH. *Bull. soc. chim.* 47, 858–85(1930).—The prepn. and properties of a series of di-primary glycols are described, also the aldehydes from which they are derived, several of which are new. Similar tables are given of a series of acetobromohydrins, and a series of amino alcs. with their benzoyl derivs. Some of these derivs. which formed colorless crystals of definite m. p. were tested as local anesthetics. They are very sol. in H_2O and alc., sol. in acetone, insol. in Et_2O and taste bitter. They have a strong anesthetic reaction which takes effect slowly. ANN NICHOLSON HIRD

Carbon monoxide poisoning and a new treatment by irradiation. F. KOZA. *Bratislav. Lekárske Listy* 9, 16–33(1929).—Ultra-violet light causes dissocn. of CO hemoglobin *in vitro* and *in vivo*. Animals and humans poisoned with CO showed marked improvement when irradiated with ultra-violet light at a distance of 60 cm. for 40 min. WILLIAM J. HUSA

Influence of arsenicals and crystalline glutathione on the oxygen consumption of tissues. CARL VOEGTLIN, SANFORD M. ROSENTHAL AND J. M. JOHNSON. *U. S. Pub. Health Repts.* 46, 339–54(1931).—The addn. of cryst. SH-glutathione to kidney, liver, testis, the Jensen rat sarcoma, and baker's yeast does not increase the rate of O_2 consumption beyond the extra amt. of O_2 required to oxidize the S of the added glutathione. Oxidized glutathione has no accelerating influence on the O_2 consumption of kidney and testis. Arsenious oxides (R.As.O.) in relatively low concn. cause a pronounced reduction in the rate of O_2 consumption. The pentavalent arsenicals ($R.AsO_3H_2$), including tryparsamide, in the same concn. are devoid of any influence on the O_2 consumption. Of the arsenobenzene derivs. ($R.As=As.R$) sulfarsphenamine is ineffective, whereas neoarsphenamine due to its rapid oxidation reduces the O_2 consumption, but less markedly than arsenoxide. These results are in harmony with observations concerning the pharmacol. and chemotherapeutic properties of these compds. which distinguish the 3 groups, $R.AsO$, $R.AsO_3H_2$ and $R.As=As.R$. SH-glutathione when added to tissues in the ratio of 10 moles to 1 mole of arsenoxide prevents the reduction in O_2 consumption caused by arsenoxide alone. S-S-glutathione is ineffective, showing that the action of SH-glutathione is due to its SH group. $FeSO_4(NH)_2SO_4 \cdot 6H_2O$ is ineffective in overcoming the reduction in O_2 consumption produced by arsenoxide. These observations add further evidence in favor of the theory that the pharmacol. action of these arsenicals is essentially due to a chem. reaction with SH-glutathione and possibly other SH compds. of protoplasm. From the physiol. viewpoint the results appear to indicate that glutathione in some as yet unexplained manner is concerned in the O_2 consumption of tissues *in vitro*. J. A. KENNEDY

Observations on the venom of a large Australian snake, Pseudechis australis. C. H. KELLAWAY AND DONALD F. THOMSON. *Australian J. Exptl. Biol. Med. Sci.* 7, 134–50(1930); cf. *C. A.* 24, 650.—Weekly "milkings" through rubber yielded 0.1 to 0.31 g. dry venom. It exerted a marked effect upon heart muscle, blood pressure and respiration, and is strongly hemolytic and anticoagulant. The lethal dose for lab. animals varied from 0.6 to 5 mg. per kg. C. G. KING

The action on mammalian circulation of the skin secretion of Hyla aurea. WM. A. OSBORNE. *Australian J. Exptl. Biol. Med. Sci.* 7, 226–8(1930).—The secretion exerts an effect like that of digitalis on the heart and like that of ephedrine on the arterioles. C. G. KING

Standardization of the trypanocidal activity of some aryl derivatives of arsenic acid. L. LAUNOY AND (MISS) ENGLER. *Bull. soc. chim. biol.* 12, 886–93(1930).—A new standard index is proposed, based upon "trivalent curative dose" (I) and "tolerance dose" (II), in which I is the av. quantity required to destroy a virulent blood stream infection of *Tr. brucei*, *Tr. evansi* and *Tr. equiperdum* in mice (held 30 days) and II is the intravenous dose tolerated by 50 to 60% of the animals. Rabbits may also be used. The index so obtained for atoxyl is taken as one and other compds. are given proportionate values, tryparsamide = 2.03 and Forneau 270 = 5.95. C. G. KING

Iodine reaction in exophthalmic goiter. WILLARD O. THOMPSON AND PHEBE K. THOMPSON. *Endocrinology* 14, 393–9(1930); cf. *C. A.* 24, 3559.—In Boston the small-

est quantity of I that produces any reduction in basal metabolism in exophthalmic goiter is greater than 0.75 mg. in $^2/_3$ of the cases. The min. amt. to produce max. reduction is 6 mg. Between these limits, the relation between the percentage approach of the basal metabolism toward the normal level and the size of the dose is roughly linear. The effective dose has not been detd. in Chicago but 6 mg. causes a marked reduction in basal metabolism. MARY E. LEAR

The role of iodine in the treatment of exophthalmic goiter. M. L. GREENSTEIN. *U. S. Vet. Bur. Med. Bull.* 7, 167–9(1931).—G. describes the beneficial effects of Lugol's soln. in a specific case. B. S. LEVINE

Experimental rabies in white mice and attempted chemotherapy. A. HOYT AND C. W. JUNGEBLUT. *J. Infectious Diseases* 47, 418–24(1930).—Prophylactic administration of various drugs (particularly arsenicals and quinine derivs.) failed to protect white mice infected intracerebrally by single or multiple minimal lethal doses. The period of incubation of the disease consistently showed a very slight prolongation following injection of Ag-arsphenamine. JULIAN H. LEWIS

The effect of barium sulfate upon the incidence of human intestinal protozoa. JUSTIN ANDREWS AND MOSES PAULSON. *J. Lab. Clin. Med.* 16, 39–42(1930).—The no. of intestinal protozoa per unit vol. of stool appears to be greatly reduced following the ingestion of $BaSO_4$. The intestinal amebas are affected more noticeably than the flagellates. The effect is transitory and is not prolonged by extension of the period of administration of $BaSO_4$. E. R. MAIN

Pharmacology of brominated oils. CLAYTON S. SMITH AND HELEN L. WIKOFF. *J. Lab. Clin. Med.* 16, 43–6(1930).—The brominated esters of cottonseed oil appear to be well adapted for use in the röntgenologic demonstration of lesions. They are eliminated from the site of injection in rabbits within a week and produce no deleterious effects in repeated doses. E. R. MAIN

Antimony in medicine. C. N. MYERS AND BINFORD THRONE. *J. Lab. Clin. Med.* 16, 239–46(1930).—A compd. (M 303) is described which contains both Sb and As in the tervalent condition. It appears to be a valuable therapeutic agent in syphilis, leprosy and diseases in which protozoal organisms are involved. An historical discussion of the use of Sb in medicine is included. E. R. MAIN

The elimination of water and sodium chloride through the kidneys after intravenous injection of isotonic sodium chloride solution. IGNAZIO SIMONE. *Biochim. terap. sper.* 17, 469–77(1930).—A soln. of 0.974% NaCl was slowly injected into rabbits. In proportion to the vol. injected a higher percentage of Cl and H_2O is eliminated; the ratio of H_2O:Cl is always the same. A. E. MEYER

A new digitalis, "Digitalis lanata" Ehrh. EM. PERROT, P. BOURCET AND RAYMOND-HAMET. *Bull. sci. pharmacol.* 38, 7–16(1931).—The plant, whose botanical description is given, contains a cryst. glucoside, dilanin, of digitalis action, but of higher potency than the cryst. digitalin of *Digitalis purpurea*. The toxicity is the same in oral administration as in intravenous injection. In contrast to *D. purpurea*, the *D. lanata* keeps up an almost const. pharmacol. activity when cultivated. The drug is not only more uniform, but also of higher content of the glucoside. A. E. MEYER

Quinidine in paroxysmal tachycardia. C. BONORINO UDAONDO. *Semana méd.* (Buenos Aires) 1930, II, 1402–7.—Quinidine sulfate (0.5 g.) dissolved in physiol. saline was given intravenously. Two cases were successfully treated. A. E. MEYER

Sinusitis treatment with lipiodol. RICARDO BRACHT. *Semana méd.* (Buenos Aires) 1931, I, 102–4.—Iodized oil, lipiodol, was injected into the sinus cavity for radiography. It is an excellent remedy. A. E. MEYER

Local inflammations treated with concentrated solution of magnesium sulfate. S. JOUAN. *Semana méd.* (Buenos Aires) 1931, I, 259–62.—A satd. soln. of $MgSO_4$ was applied in a permanent bandage on the inflamed area. Forty cases were successfully treated. A. E. MEYER

Influence of insulin on the glycogen content of the perfused rabbit liver. NIELS A. NIELSEN. *Biochem. Z.* 230, 259–68(1931).—On perfusing the rabbit liver with defibrinated blood without insulin there is a gradual decrease in the sugar content of the blood and a corresponding increase in the liver glycogen. The deposition of the glycogen in the liver is not uniform. Addn. of $^1/_3$ to 20 units of insulin to the blood causes a rise in the blood-sugar concn. and a loss of glycogen in the liver. No effect was observed with amts. smaller than $^1/_3$ insulin units. S. MORGULIS

Influence of fermentation poisons upon experimental tumors. I. L. KARCZAG. *Biochem. Z.* 230, 411–9(1931).—Enzyme and protoplasm poisons have been differentiated upon the basis of their effect in inhibiting the fermentation of (1) both yeast and zymin (protoplasm and enzyme poison), (2) zymin alone (enzyme poison), or (3)

yeast alone (protoplasm poison). By this method it was possible to discover substances which injured the glucolytic enzyme without producing any poisoning effect upon the protoplasm. The N of the biologically active mol. plays a paramount role, especially the NO_2 and the CN groups, and not in the nucleus but in the side chains of the compd. By the same method substances were discovered which are protoplasmic poisons. It was then attempted to select substances such as isoquinoline red, Magdal red, ethyl red, Martius yellow, Mikado yellow, bromothymol blue, propionaldehyde, cyanohydrin, nitrobenzaldehyde, *o*-nitrobenzonitrile, which, because of their relative nontoxicity could be employed in animal expts. to treat tumors. No consistent results were obtained, although with isoquinoline red, Magdal red and ethyl red a definite influence was noted. II. L. KARCZAG AND C. SELLEI. *Ibid* 420–34.—Ethyl red, chrysoidine, Magdal red, isoquinoline red and Martius yellow, which are inhibitors of the yeast fermentation process, were found to exert an inhibiting action on the glucolysis of tumor cells which diminishes in the order given above. These substances also cause a diminution of the respiration in the same order so that Martius yellow either had no influence upon the respiration of the tumor cells or actually stimulated it. These enzyme poisons act upon several enzymes so that both the fermentation and the respiration enzyme are simultaneously inhibited, and in this respect they differ from the KCN which injures the respiratory enzyme much more than the glucolytic enzyme. Furthermore, whereas the action of KCN on glucolysis is reversible, the effect of the above substances is irreversible. *In vitro* the effect of these enzyme poisons can be superimposed upon the action of KCN, but when used subcutaneously in animals the KCN effect predominates. The substances which were found to be toxic for the fermentative activity of both tumor and yeast cells were also toxic for the fermentation by *B. coli*. It is usually easier to influence glucolysis than respiration, and it is therefore concluded that the therapeutic efforts, so far as the metabolism of the tumor is concerned, must be directed toward the respiratory function. It is suggested that results could only be expected by definitely and permanently inhibiting their respiration while leaving the glucolytic ability unchanged or slightly lowered. III. L. KARCZAG. *Ibid* 435–8.—The sugar content of Ringer soln. mixed with sarcoma powder increases. Fermentation of the glucose proceeds slowly and continuously in such a mixt., though the controls show no fermentation in the same time. Conclusion: Rous sarcoma can ferment glucose with liberation of gas and this process can be studied also *in vitro*.
S. MORGULIS

The action of certain autonomic drugs upon the pigmentary responses of Fundulus. DIETRICH C. SMITH. *J. Exptl. Zool.* 58, 423–53(1931).—Certain sympathetic and parasympathetic stimulants (cocaine, ergot, pilocarpine, physostigmine, atropine) were injected into the body cavity of the fish, *Fundulus heteroclitus*, and the effects upon the dermal melanophores were studied. Cocaine in sublethal doses produces a contraction, in lethal doses an expansion of the melanophores. Ergot produces a stellate condition of the melanophores which then respond to temp. changes like denervated melanophores. Pilocarpine and physostigmine retard the normal responses of the melanophores. High concns. produce permanent expansion. Atropine produces a stellate condition but unlike pilocarpine the melanophores still respond to background shade. Lethal doses produce complete expansion but the melanophores respond to temp. changes like innervated melanophores. In appropriate dosage atropine antagonizes the action of pilocarpine but not of cocaine. The melanophores of fishes possess a double rather than a single innervation. C. H. RICHARDSON

Adsorption and narcotic action. H. H. KING, J. LOWE HALL, A. C. ANDREWS AND H. L. COLE. *J. Pharmacol.* 40, 275–89(1930).—The authors detd. the free surface tensions of drugs in aq. solns., the interfacial tensions of aq. solns. against pure liquid paraffin and against a liquid paraffin soln. of lecithin, and calcd. the adsorption at various concns. The drugs used were: trional, butyl chloral hydrate, sulfonal, bromal hydrate, triacetin, diacetin, chloral hydrate, Et carbamate, monoacetin, Me carbamate, Et Me carbamate. A comparison of the compds. in homologous series showed that the free surface tension and the adsorption in each series decreased as the liminal values (as detd. by Meyer) increased. The calcd. adsorption values increased as the liminal values decreased in the series with pure paraffin. For the paraffin-lecithin series the results were not so regular. C. RIEGEL

Chloroform content in various tissues during anesthesia and its relationship to the theories of narcosis. JAMES L. MCCOLLUM. *J. Pharmacol.* 40, 305–25(1930).—Dogs were anesthetized with $CHCl_3$ and the blood and tissues analyzed for $CHCl_3$ content. The corpuscles contained more $CHCl_3$ than the plasma and more than their lipoid content would indicate. The $CHCl_3$ content of the brain and tissues increased grad-

ually, but at the point of highest concn. (for the brain) there was less $CHCl_3$ than the lipoid content would indicate was possible. C. RIEGEL

Number of open glomeruli in acute mercuric chloride nephrosis. ROBERT A. MOORE AND LOUIS M. HELLMAN. *J. Exptl. Med.* 53, 303–6(1931).—Acute Hg nephrosis in the rabbit is not assocd. with a decrease of glomerular circulation. C. J. W.

Effects of the intravenous injection of colloidal silver upon the hematopoietic system in dogs. SAMUEL S. SHOUSE AND GEORGE M. WHIPPLE. *J. Exptl. Med.* 53, 413–20 (1931).—Colloidal Ag has no sp. action on the bone marrow in dogs but is a systemic poison which may cause anorexia, weakness, loss of wt., anemia and death. Hemolysis can be demonstrated after large doses of colloidal Ag and the anemia presumably is due in part at least to a destruction of red blood cells in the peripheral circulation. The colloidal Ag, injected intravenously, is deposited as granules almost exclusively in the cells of the reticul-endothelial system after the manner of particulate substances. Repeated injections of non-lethal amts. of this substance are invariably followed by hyperplasia of the bone marrow. Large single doses cause rapid death in 12 hrs. or less, characterized by pulmonary edema and congestion. C. J. WEST

Aplasia of marrow and fatal intoxication in dogs produced by Röntgen radiation of all bones. SAMUEL S. SHOUSE, STAFFORD L. WARREN AND GEORGE H. WHIPPLE. *J. Exptl. Med.* 53, 421–35(1931). C. J. WEST

The combined effects of colloidal silver and highly filtered Röntgen radiation upon the hematopoietic system in dogs. SAMUEL S. SHOUSE AND STAFFORD L. WARREN. *J. Exptl. Med.* 53, 437–45(1931).—The individual destructive effects of colloidal Ag and heavily filtered radiation are still evident when the 2 are used together; the combined effects are cumulative in that small doses are more destructive than when either is used alone. The leucocytosis resulting from the injection of the colloidal Ag affords no protection against the terminal leucopenia following the radiation. C. J. W.

The effect of amyl nitrite on the size of the heart and the width of the aortic shadow as determined röntgenologically. WM. A. BRAMS AND HERMAN A. STRAUSS. *Am. J. Med. Sci.* 180, 618–20(1930).—Six normal and 15 arteriosclerotic persons were studied röntgenologically before and after administration of $AmNO_2$. The transverse diam. of the heart shadow was reduced in 18 of the subjects; the presence or absence of arteriosclerosis seemed to play a minor role in these changes. The width of the aortic shadow was increased in 13 of the 21 patients after $AmNO_2$ administration. This result was independent of the condition of the peripheral vessels or the degree of blood pressure. R. C. WILLSON

The action of thymophysin on the human pregnant uterus in situ. M. PIERCE RUCKER. *Am. J. Obstet. & Gynec.* 20, 791–7(1930).—After an intramuscular injection of 0.5 cc. of thymophysin in a case at term there was apparently no change in the type of uterine contractions or in the tone of the uterus. A dose of 1 cc. in a case in the fifth month of pregnancy showed an increased frequency, a decreased force of contractions and an increase in the tone of the uterus between contractions. The same dose produced similar but more marked changes in cases at term. R. C. WILLSON

A study of the effect of acriflavine given intravenously on experimental uterine infection in the dog. JOSEPH L. MEYERS. *Am. J. Obstet. & Gynec.* 20, 760–74(1930).—An appropriate dose of acriflavine given intravenously has a definite beneficial effect on the course of the experimentally infected uterus of the dog. The earlier the dye is injected the greater is the effect. In some instances sterile cultures of the inoculated or infected uterine horn are obtained after acriflavine therapy. R. C. WILSON

Cerebral blood flow. I. The effect of intravenous administration of hypertonic and hypotonic solutions on the volume flow of blood through the brain. COBB PILCHER. *Arch. Neurol. & Psychiatry* 24, 899–906(1930).—The O content of arterial blood and blood from the occipitovertebral sinuses in the dog was studied before and after the intravenous injection of 50% dextrose or 30% NaCl and of distd. water. The O content varied immediately after the injections but became stable within 30 min. and remained so for several hrs. The O content from the occipitovertebral sinus was invariably diminished markedly after the injection of both hypotonic and hypertonic solns. The arterio-venous difference (utilization of O) increased after injection of both types of solns. **II. The effect of intravenous injection of hypertonic and hypotonic solutions on the cardiac output and blood pressure.** *Ibid* 907–12.—The cardiac output was usually diminished after injection of both types of solns. The O consumption and O utilization were usually increased by both types. The mean blood pressure varied during the injection but thereafter was increased slightly in all expts. R. C. WILLSON

The effect of potassium iodide on the pulse rates of normal individuals. DONALD

McEachern. *Bull. Johns Hopkins Hosp.* **47**, 299–303(1930).—In the absence of thyroid disease or other interfering circumstances, KI produced significant increases in pulse rate in 12 subjects while 5 showed a slight decrease. The changes came on gradually about the third to seventh day and reached the max. at about the tenth day. Normal rate was restored within a week or so after the drug was discontinued.
R. C. Willson

The effect of the ingestion of potassium iodide on the electrocardiogram of normal individuals. Donald McEachern and B. M. Baker. *Bull. Johns Hopkins Hosp.* **47**, 304–7(1930).—KI in therapeutic doses has no significant effect. R. C. Willson

The effect of lead on the isolated uterus. M. D. Devlet-Kildeeva and B. A. Raikhstein. *Kazansky Meditsinsky Jurnal* **26**, 690–4(1930); *J. Am. Med. Assoc.* **95**, 1545.—After a graphic record had been made of the normal muscular contractions of a part of the uterine cornu in cats placed in Ringer's or Locke's soln. kept at 38° with a const. stream of O flowing through the soln., Pb acetate was added gradually to the soln. The uterine contractions changed with the concn. of the Pb acetate. When this reached 1:200 the uterus reacted by a complete tetanus and the muscular contractions could not be made to reappear even after all traces of the Pb acetate had been washed out. The introduction of Pb acetate into the blood stream of cats also produced a hypertonic condition of the uterus. R. C. Willson

Antagonism between adrenaline and ergotamine, and the respiratory quotient. R. Capo. *Riforma Medica* **46**, 1347–53(1930); *J. Am. Med. Assoc.* **95**, 1703.—Ergotamine does not modify the greater consumption of O induced by adrenaline, but when administered during fasting it causes a notable lowering of the elimination of CO_2 and a reduction of the R. Q. Adrenaline causes a mobilization of hepatic glycogen and thus increases almost constantly the elimination of CO_2 and rises the R. Q. Ergotamine inhibits the hyperglucemia that is induced by adrenaline without modifying the increased intra-org. combustion caused by the latter. R. C. Willson

Iodoxybenzoate as a test reagent for free phenolic hydroxyl groups in organic compounds (Leake) **7**. Trypsin preparations suitable for the prevention of adhesions (Walton) **17**. Derivatives of anesthesin (Coniglio) **10**.

Anschütz, W., Specht, K. and Tiemann, Fr.: **Die Avertinnarkose in der Chirurgie.** Berlin: J. Springer. 200 pp. Reviewed in *J. Am. Med. Assoc.* **96**, 715(1931)

I—ZOOLOGY

R. A. Gortner

Amylase in the extracts of the salivary glands of the silk-worm larva (Bombyx). S. Matsumura. *Bull. Sericulture and Silk Ind.* (Japan) **2**, 4–5(1930).—Aq. glycerol exts. of the salivary glands of the silkworm hydrolyze sol. starch to dextrin and sugar and glycogen to dextrose with optimum activity at p_H 6.6–7.1. In the absence of NaCl the enzyme is almost inactive. Exts. made from European varieties of silkworm are less active than similar prepns. from the Chinese and Japanese varieties.
B. C. A.

Cardiac hormone in the tortoise. A. de Carvalho. *Compt. rend. soc. biol.* **102**, 535–37(1929).—Elec. irritation, and the action of pilocarpine, atropine, ephedrine and ergotamine on the heart of a tortoise failed to detect a cardiac hormone. B. C. A.

Action of hypophyseal extract on egg production of batrachians. R. Kehl. *Compt. rend. soc. biol.* **103**, 744–5(1930); *Physiol. Abstracts* **15**, 248.—The alk. aq. ext. of the anterior lobe of the hypophysis of mammals, when injected into *Discoglossus*, rapidly elicits the free laying of eggs in the females captured in Dec. and Jan. Controls which are kept in the same conditions of fasting, etc., do not lay their eggs. G. G.

Cause of ammoniacal odor of flesh of the shark. O. Martin. *Z. Fleisch Milch-Hyg.* **40**, 48–9(1929).—The NH_3 arises from urea (up to 2.5% of the flesh), the origin of which is not pathol.; it serves to maintain the internal osmotic pressure against that of the water. B. C. A.

Amino acids of tissues. IV. The diamino acid content of muscle tissue of different classes of animals. John L. Rosedale and Joseph P. Morris. *Biochem. J.* **24**, 1294–6(1930); cf. *C. A.* **24**, 164.—An increase in the amt. of histidine N and a decrease in lysine N are found in the lower organisms (tissue of crocodile, cockroach, mosquito larvae, oysters and sponge). **V. Monoamino acids of the horse mackerel (Caranx rottleri).** *Ibid* **24**, 1297–1300.—The monoamino acids are extd. with BuOH Better results are obtained by first removing some of the amino acids from soln.
Benjamin Harrow

The hydrolytic products of the protein from the egg capsule of the gastropod, Hemifusus tuba Gmel. JUN-ICHIRO SAGARA. *J. Biochem.* (Japan) **12**, 473–4(1930).—The protein of the egg capsule of *Hemifusus* seems to belong to the albumoids, being in some respects similar to keratin and in other respects to elastin. It contains no glycine, tyrosine or histidine, but much leucine and glutamic acid, these 2 amino acids making up 30% of the protein. S. MORGULIS

A qualitative analysis of the digestive secretions of the larva of the Japanese beetle (Popillia japonica Newn). MILLARD C. SWINGLE. *J. Econ. Entomol.* **23**, 956–8 (1930).—A qual. chem. examn. of the digestive secretions of this larva showed the presence of ions of Al, Fe^{++}, Ca, Mg, K, Na, NH_4, CO_3, Cl, NO_3 and PO_4. C. H. R.

Investigations on the rapid coloration of the cilia of ciliates. HÉLÈNE ANSELMIER. *Pharm. Acta Helv.* **5**, 33–41, 64–71, 88–94(1930).—Detailed directions are given for the differential staining of the cilia of ciliates, thus making it possible rapidly to diagnose ciliates in mixed cultures of infusoria. Photomicrographs of certain protozoa of various origins, and a bibliography of 10 references accompany this highly specialized study. S. WALDBOTT

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Amendment of July 8, 1930, to the Federal food and drugs act and requirements thereunder. ANON. Food and Drug Administration, U. S. Dept. Agr., *Service and Regulatory Announcements* F. D. No. 4(1931).—The forms of statements required on *canned foods* of substandard quality and substandard fill, together with standards for fill of container of all canned foods and of quality and condition for *peas, peaches* and *pears*, are given. H. A. LEPPER

Color and flavoring problems in the food industries. T. H. FAIRBROTHER. *Food Manuf.* **6**, 72–5(1931). E. H.

Possibility of use in foods of coloring materials made in Italy. C. MANUELLI AND R. MAGGIORA. *Atti III congresso naz. chim. pura applicata* 1930, 627–35.—The characteristics of coloring materials allowable in foods are reviewed. E. M. SYMMES

Reaction between metal receptacles and foodstuffs. I. Relation of metals to fluids (drinks): corrosion. B. BLEYER AND J. SCHWAIBOLD. *Biochem. Z.* **230**, 136–45 (1931).—The corrosion of various metals (Al, Zn, Fe, Ni, Sn, Pb, Cu, Ag, brass) by water, tea and coffee has been studied and the extensive findings are recorded in tables and curves. S. MORGULIS

Determining the swelling rate in canned foods. W. S. STURGES, E. T. DRAKE AND L. B. PARSONS. *Food Ind.* **3**, 105(1931).—A quant. method for the measurement of swelling rate of Sn cans is given. The principle of the method consists in weighing the can under H_2O and also in air. $S = 100\ W/V$, where W is the decrement in wt. in H_2O, V = wt. in air − wt. in H_2O, and S is the % swell. C. R. FELLERS

The p_H values of New Zealand wheats and flours. J. K. DIXON. *New Zealand J. Sci. Tech.* **12**, 146–53(1930).—The p_H and buffer-effect values of ground whole-wheat flour prepd. in the lab. and com. flour were detd. Exts. prepd. by the Kent-Jones method were used in a quinhydrone cell coupled with a calomel half-cell. One hr. was required to get a correct reading. The Pt electrodes poisoned readily. The results showed that the quality of a com. flour as detd. by the baking test cannot be predicted from the p_H or buffer-effect value of its wheat or flour prepd. in the lab. The p_H and buffer-effect values of flours are governed by the treatment each wheat receives at the mill and bear no relation to the values found for samples prepd. in the lab., although the lab. values may be of some assistance to the miller in choosing the method of treatment to be adopted for each lot of wheat. L. E. GILSON

Utilization of the soy bean. IV. Electrolytic oxidation of the hydrolyzate of proteins. I. YOSHITARO TAKAYAMA. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding, 31–2(1931); cf. *C. A.* **24**, 2810.—Crude soy-bean protein was hydrolyzed with H_2SO_4. The hydrolyzate was filtered from humin and electrolyzed with a peroxidized Pb anode and a Pb cathode in an undivided cell (anodic c. d. 2 amp./sq. dm.); the soln. was then steam-distd. The distillate was neutralized with NaOH and redistd. The volatile acids remaining as Na salts were 9.6% of the crude protein. A mixt. of free acids was obtained from the salts by addn. of phosphoric acid and fractionated at 95–195°, sepg. formic and isovaleric acids and AcOH, with small quantities of propionic and butyric acids. The residual soln. of the steam distn. was distd. over CaO under reduced pressure into HCl. The volatile base obtained was pure NH_4Cl. The relation between NH_4N

produced and elec. quantity consumed was detd. In the same way, formic and isovaleric acids and AcOH were obtained from gluten hydrolyzate. E. M. SYMMES

"Vaingan" rice cultivation in south Konkan. R. M. HEGDEKATTI. *Poona Agr. Coll. Mag.* **22**, 146–59(1930).—The term "vaingan" is given to rice grown by means of lift irrigation during the hot summer weather. As compared with rainy season rice, "vaingan" rice kernels and bran are richer in albuminoids and digestible carbohydrates and poorer in woody fiber and ash, particularly siliceous ash. "Vaingan" rice straw contains more digestible carbohydrates and albuminoids than rice straw from a rainy season. K. D. JACOB

The determination of starch in cereal products. C. W. HERD AND D. W. KENT-JONES. *J. Soc. Chem. Ind.* **50**, 15–22T(1931).—Methods for detg. starch are broadly classified as: (I) hydrolytic methods, (*a*) acid hydrolysis, (*b*) enzymic hydrolysis; and (II) non-hydrolytic methods. The "by-difference" method and the method of direct washing out from dough are in the latter category. Some of these methods are discussed in detail and the relative results obtained by the application of them to different mill stocks are considered. These stocks included: (1) com. starches, (2) com. flours and mill stocks, (3) wheat offals, and (4) whole wheats. Conclusions: By "starch" different observers mean different things. The modified Rask method is suggested as of the greatest utility, while hydrolytic methods are open to grave suspicion. The modified method is: Place 1 g. of material and 1 g. acid-washed sand in a centrifuge tube, mix and cover with washed Et_2O, stir, centrifuge and pour off the liquid. Make 2 addnl. washings and to the residue add 25 cc. of water and 0.25 cc. *N* NaOH, mix and after 15 min. add 5 cc. pure MeOH and mix again. Mix in 5 cc. dil. MeOH (2:1 water), centrifuge this mixt. and remove the alc. layer. Wash the residue twice with 10 cc. of dil. MeOH and finally thrice with water. Stir the residual mass into a thick paste with a few cc. of water, add a total of 20 cc. of water to transfer to a 100-cc. flask, add 20 cc. concd. HCl and make up the vol. to 100 cc. with Rask's acid. Filter the contents of the flask by suction through a Gooch crucible contg. asbestos and a layer of acid-washed sand into a small dry suction flask. Transfer 50 cc. to a 200-cc. beaker contg. 110–5 cc. 96% alc., and immediately after pipet drainage, stir the resulting mixt. 1 min. or until the ppt. becomes flocculent. When it has settled, transfer the contents of the beaker to a centrifuge tube, centrifuge 10 min. and remove the supernatant liquid. Wash the residue with 70% (by vol.) alc. and twice with 96% alc. Wash the ppt. with Et_2O, dry the crucible at 40° for 10–15 min. and then at 130° to const. wt. W. H. BOYNTON

The determination of starch in flour by diastase-acid hydrolysis. B. G. HARTMANN AND F. HILLIG. *J. Assoc. Official Agr. Chem.* **14**, 112–6(1931).—A detailed description is given of a modification of the technic of the official A. O. A. C. method for the detn. of starch by diastase-acid hydrolysis. The time required for starch conversion by diastase is reduced from 2 hrs. to 20 min. by introducing a preliminary pepsin digestion (cf. *C. A.* **21**, 287), but the total working time required for the peptic-diastatic digestion is about 3 hrs. The peptic digestion increases the starch yield appreciably; this is shown to be due to the fact that the starch is rendered more accessible to diastatic hydrolysis and not to any reduction by the pepsin or the products of its action. In the pepsin digestion an acidity adjustment corresponding to 5 cc. *N* HCl per 100 cc. of substrate is made; after the digestion the acidity is carefully neutralized, the mixt. is slightly acidified with HCl, and finally treated with $CaCO_3$ to assure a practically neutral condition for the diastatic inversion. The official method was also modified in regard to the removal from the flour of the sugars and free fat; the procedure proposed, though time-consuming, is easy to carry out and gives satisfactory results with ordinary care, even in the hands of analysts inexperienced with it. A. PAPINEAU-COUTURE

Starch explosion hazards reduced by safety measures. D. J. PRICE AND H. R. BROWN. *Food Ind.* **3**, 106–7(1931).—Explosions of dry starch are relatively frequent and are usually caused by sparks from machines, motors, etc., or by static electricity. A serious explosion at Decatur, Ill. is described. Safety measures are outlined. C. R. FELLERS

Estimation of the age of flour. W. HARTMANN. *Z. Untersuch. Lebensm.* **59**, 364–79(1930).—Samples of flour and bread (33.3 g.) were extd. for 6 hrs. with boiling petr. ether or $CHCl_3$, and the n at 40° and the acid value of the ext. detd. Flours recently mill-ground had acid values of 54 to 76 and 46 to 64 when contg. 60% of rye and wheat flour, resp., while the corresponding figures for flours of the same compn., ground in the lab. and left for 24 hrs., were 44 and 39. Bleached flours were not included. Extns., after various intervals, showed that the acid value increases with time of storage, rapidly at first, to about 240 after 15 months. Gluten N, lecithin phosphate contents and

n decrease on storage at a rapid rate, particularly in the initial stages. The acid value and *n* of the unground grain, however, showed little alteration on storage. Reductions in *n* were observed for bread baked from rye and wheat flours, while the acid value was increased in the latter case only. The lecithin phosphate fell from 6 to 1.3 mg. per 100 g. of flour in both cases. The bacterial contents were also detd. on samples 5 to 15 months old; in the presence of growths of *Oidia*, small quantities of an unsaponifiable wax-like substance were obtained. In view of statements that flour is no longer suitable for baking purposes after 6 months' storage, it is suggested that the max. permissible acid values in such cases should normally be 120 to 150 for 60% rye flours, and 90 to 100 for 60% wheat flours. C. R. FELLERS

Direct determination of available carbon dioxide in baking powder. MAYNE R. COE. *J. Assoc. Official Agr. Chem.* **14**, 99–101(1931).—In the gasometric method adopted by the A. O. A. C. for the detn. of CO_2, 2 detns. must be carried out to obtain available CO_2, which is the difference between the total and residual CO_2. The following new method is proposed; the same app. is used and only 1 detn. is required. Run 25 cc. of 5% $(NH_4)_2SO_4$ soln. into the 250-cc. decompn. flask contg. 1.7 g. of baking powder, heat at boiling temp. till all gas is evolved, cool to room temp.; when equil. is established (generally in about 15 min.) read the amt. of available CO_2 on the graduated tube and make the necessary temp. and pressure corrections. Total CO_2 also can be detd. in a few min. with the same sample, without detaching the flask from the app., as follows: Fill the buret contg. a few cc. of $(NH_4)_2SO_4$ with H_2SO_4 (1 + 5), run 25 cc. into the flask, heat almost to boiling, let cool as before, take the reading, subtract a no. corresponding to the no. of cc. of acid used from the no. of cc. found, and correct for temp. and pressure. $(NH_4)_2SO_4$ is used as reagent because (1) a satisfactory evolution of CO_2 is obtained from all varieties of baking powder; (2) it acts as a protein coagulant for powders contg. egg albumin, thus serving as a foam destroyer; (3) if distd. water is used with phosphate powders and those contg. egg albumin, low results are obtained, but with 5% $(NH_4)_2SO_4$ soln. the same results are obtained as with the gasometric method; (4) if the total CO_2 value is desired the acid reagent may be used to evolve the residual CO_2 remaining in an $(NH_4)_2SO_4$ soln. The technic of the method is described in detail. It gives results checking with those of the gasometric method as closely as would duplicates by the latter method. A. PAPINEAU-COUTURE

The function of emulsions of oil and water in breadmaking, with special reference to gluten formation and modification. J. C. VAN DYK. *J. Soc. Chem. Ind.* **49**, 421–2T (1930).—Glutens obtained from doughs which had been made up with emulsions are softer and more elastic. When the gluten is dried in a hot-air oven at 105°, the color of the baked gluten is superior to that obtained by drying off the glutens from a dough of flour and tap water. It is very difficult to wash out doughs made from flour and emulsions, and in order to prevent dispersion the starch must be filtered through fine muslin. Emulsions of oil and water increase the amt. of gluten in the flour to a very small extent. This contradicts Bennion (*C. A.* **21**, 613). There seems to be no definite relation between the fact that emulsions of oil and water keep bread moist for a long period, and the increase of gluten. As the washing free from starch is very difficult, it seems that the increase of gluten reported by B. was caused by some const. error connected with the washing out of the gluten. ALBERT L. HENNE

Phosphatide content of different breads. B. REWALD. *Z. Untersuch. Lebensm.* **60**, 315–8(1930).—The phosphatide contents were detd. by R.'s method (*C. A.* **23**, 3940), the sample being extd. in succession with a large excess of acetone and a mixt. of C_6H_6 and EtOH. The exts. were evapd. separately, the residues extd. with dry Et_2O, and the P was detd. in each case in the residue after evapn. of the Et_2O. The sum of these 2 figures was taken as the total phosphatide content, the following percentage of the dry samples being found: Rye bread crumb or crust 0.174, crumb and crust of white bread 0.287, crumb and crust of pumpernickel 0.073, black bread crumb 0.183 and crust 0.194, graham bread crumb 0.267 and crust 0.302. The respective P contents of the residues after extn. were 0.20, 0.24, 0.32, 0.34, 0.35, 0.30 and 0.29%. With the exception of pumpernickel, the different breads examd. contained approx. the same amts. of phosphatide. Similarly, the P contents of the residues were approx. equal in all cases. Temp. is without influence on the phosphatide content because both crust and crumb had the same amts. Yeast fermentation was also without effect on the phosphatide of bread. C. R. FELLERS

The extinction coefficient of milk. A. SCHNECK AND H. MENGEBIER. *Milchwirtschaft. Forsch.* **11**, 1–29(1930).—The light transmission is proportional to concn. under strictly controlled conditions. The Lambert-Beersche rule may be employed. The fat phase has little effect. In dilns. of 1–100 the results satisfy the Lambert-Beersche rule. Many

samples tested show the extinction to be depressed 4% by skimming. Milks from different cows have different extinction coeffs. It is shown that the extinction coeff. due to fat varies with the av. size of the fat particle. GEORGE R. GREENBANK

The residual nitrogen of cow milk. F. KIEFERLE AND J. GLOETZL. *Milchwirtschaft. Forsch.* 11, 62–117(1930).—The authors consider the residual N of milks as analogous to that of blood and urine. They ppt. the coagulable protein by heat and 10% AcOH. The N remaining in the filtrate is called total residual N. The total residual N for an individual milk is 84.8 mg. % per 100 cc. when the total N is 531.7 mg. %; for herd milk it is 66.3 mg. % for a total N of 533.1 mg. %. If the hexone bases are removed by Na tungstate and trichloroacetic acid the residual N for an individual milk is 28.4 mg. %. The values for the total residual N in mg. % of the constituents for individual and herd milk are, resp., albumoses 30.7, 27.2; peptone 24.2, 18.7; amino acids 3.9, 4.6; NH_3 1.3, 1.1; urea 13.4, 10.1; creatinine 2.3, 1.7; creatine 3.1, 2.2; uric acid 2.1, 1.5. The total residual N increase in pasteurization is 10.4% and in boiling 18.6%. GEORGE R. GREENBANK

Proteolysis of milk. H. HARTWIGK. *Milchwirtschaft. Forsch.* 9, 339–54(1930).—The detn. of caseolytic organisms in milk is described; the detn. of NH_3 by distn. in a vacuum and the detection of peptone are also of value. Tryptophan was not detected. The catalase value is not always parallel with the no. of proteolytes. B. C. A.

Has "chromiform," the new milk preservative, proven its value? FONZES DIACON. *Ann. fals.* 24, 22–5(1931); cf. *C. A.* 23, 913.—The previous investigation established the value of "chromiform" when added to fresh milk. Evidence is now presented showing that, when added to milk several hrs. old, "chromiform" is a much better preservative than either $K_2Cr_2O_7$ or $(CH_2O)_3$ alone. A. PAPINEAU-COUTURE

Influence of formaldehyde on the precipitation of milk protein material. MARCEL MASCRÉ AND EMILE BOUCHARA. *Bull. soc. chim. biol.* 12, 994–1000(1930); cf. *C. A.* 24, 5052.—Addn. of up to 20% formol to milk caused more AcOH to be required for pptn. of casein, but less N was left in soln. after pptn. was complete, and there was less re-soln. upon adding an excess of acid. A similar effect was exerted upon the pptn of total milk proteins by CCl_3COOH. C. G. KING

Souring of milk. I. W. GRIMMER AND W. PAAPE. II. W. GRIMMER AND C. ARLART. *Milchwirtschaft. Forsch.* 9, 88–99, 100–20(1929); cf. *C. A.* 23, 3990; 24, 3025.—Rennin coagulum and the residue of milk on porous plates differ in that the N, Ca and P contents of the latter are the smaller. Possibly in coagulation by rennin dissolved Ca and P are co-pptd., or combination of $Ca_3(PO_4)_2$ with caseinogen or casein occurs. With progressive souring the Ca content of the coagulum diminishes fairly regularly. If $\sqrt{kS}$ is the H-ion concn. of lactic acid of acidity x, c is a factor and S is the H-ion concn. of the milk, $y = cx^3\sqrt{kS}$. The value of c was 3.03–5.42 (av. 4.3) $\times 10^{-6}$. B. C. A.

The foaming problem. W. MOHR AND C. BROCKMAN. *Milchwirtschaft. Forsch.* 11, 48–61(1930).—Milk with the greatest surface tension and viscosity produces the most stable foam. The foaming properties are greatly changed by the addn. of Na citrate. The solidity and stability of the foam are greatly diminished by the salt. There is a relation between the foaming and the surface viscosity. The tendency to foam depends on the ability to form a surface. Solidification of the wall gives a measure of the surface viscosity but not of the stability. It requires an optimum surface viscosity for a stable foam. With increasing fat foam formation and stability decrease. Foam formation is greater when the fat is liquid than when solid. Homogenization of skim milk reduces foaming; with whole milk it is increased. The influence of temp. varies with different milks. The optimum is from 30° to 60°. Repeated foaming does not decrease the capacity. Churning reduces the capacity of the skim milk. G. R. G.

Detection of heated milk. K. EBLE AND H. PFEIFFER. *Z. Untersuch. Lebensm.* 60, 311–4(1930).—Of the several variations of the *benzidine test* for the detection of heated milk, the following method gave the most satisfactory results: shake 5 cc. of milk with 0.5 cc. of a 4% soln. of benzidine in 96% EtOH, add 1 drop of a 1% soln. of H_2O_2 after 1 min., and shake the mixt. again. Raw milk gives a stable blue-green color, milk heated for 30 min. at 63° gives a transient blue-green color, while strongly heated milk is colorless. After 1 min. add 10 cc. of a satd. soln. of $MgSO_4$ and shake the mixt.; raw milk becomes gray-green gradually turning to blue-green in about 10 min.; heated milk is gray-green and gradually becomes grayish blue. After 10 min. more dark blue curds sep. from the slightly heated milk, while in the strongly heated milk the curds are white. If $MgSO_4$ is replaced by Na_2SO_4, the respective colors are chocolate

to violet-brown and green-brown. Heated milk having an abnormally high leucocyte content or lactic acid acidity, or milk heated for a short time below 63°, tends to give the color reactions of raw milks, and it is desirable before making the test to add 0.25 *N* KOH soln. to reduce the acidity to 0.06% lactic acid. These exceptions are due to the peroxidase assocd. with the proteins or leucocytes of the milk, which normally passes into soln. when the milk is heated and hence loses its activity, but may be activated by lactic acid and inactivated by the addn. of AmOH. In doubtful cases a mixt. of 10 cc. of milk, 10 cc. of a satd. soln. of $MgSO_4$ and 1 cc. of a 20% soln. of AcOH is shaken and centrifuged for 6 min. at 120 r. p. m. Slightly heated milk gives a clear serum, raw milk a definitely opalescent serum, and mixed milk contg. 20% or more of raw milk, a faint turbidity. C. R. FELLERS

Pseudomonas as a cause of bitter milk. R. W. NEWMAN. Calif. Dept. Agr., *Monthly Bull.* 19, 640(1930). C. R. FELLERS

Anaerobic spore test as an index of contamination in milk. M. H. KNUTSEN AND E. C. HOLST. Penn. Agr. Expt. Sta., *43rd Ann. Rept. of the Director in Bull.* 258, 29(1930).—The addn. of reduced Fe increased the efficiency of the test, but even this improved technic failed to show any decided degree of accuracy in differentiating milks as to the amt. of manurial contamination. One of the principal reasons the test is invalid is because anaerobic spores germinate after varying periods of time depending upon the temp. of incubation and other factors. C. R. FELLERS

The physicochemical constitution of spray-dried milk powder. L. H. LAMPITT AND J. H. BUSHILL. *J. Soc. Chem. Ind.* 50, 45–54T(1931).—It is shown that the figures obtained for fat content (Soxhlet) are not comparable to the "free" fat as detd. by the standard method as described. The normal moisture content of com. milk powders has no effect on the amt. of "free" fat. The "free" fat content of 8 com. spray-process powders is given, showing that the percentage calcd. on the total fat may vary between 3.33 and 14.22; for roller-process powder it is between 91.6 and 95.8. Increasing the surface of the particles of spray-process powder by grinding 3 hrs. increases the "free" fat up to 83% of the total, but in the roller-process powder practically all of it is free. The differences in the systems of drying which may influence the constitution of the particles are pointed out. Attempts to simulate the Soxhlet mechanism by a repetition series of standing extns. has thrown some light on the differences observed. It is shown that when milk powder absorbs moisture certain well-defined changes take place and that a first "clammy" stage is succeeded by the development of a dry, hard and powdery texture. This change is accompanied by a freeing of the fat. It is proved that there is a definite range of moisture content at which the fat is freed; this is called the "critical moisture content" by the authors. Microscopical examn. proves this change to be accompanied by the crystn. of the lactose, and this crystn. is also produced by treatment with 96% alc. Spray-process lactose is amorphous but crystallizes under the effect of exposure to moist air or to treatment by 96% alc. Time is a factor in the freeing action of absorbed moisture; powder freshly made reacts more slowly than an older one. The fat-freeing action of moisture is irreversible. The crit. moisture range is independent of the fat content and proportional to the amt. of solids-not-fat in the powder. It is not possible to put forward a definite theory concerning the structure of the milk-powder particle. The lactose in its amorphous state has an important effect on the availability of the fat to solvents, and any means so far tested by which the lactose is caused to crystallize results in the freeing of the fat. J. C. JURRJENS

Butter-fat test in condensed and evaporated milk. W. D. SWOPE, C. D. DAHLE AND F. J. DOAN. Penn. Agr. Expt. Sta., *43rd Ann. Rept. of the Director in Bull.* 258, 26(1930).—The method for sweetened condensed milk is that previously given (*C. A.* 24, 4869). In testing evapd. milk, excellent results were obtained by using 3 cc. of NH_4OH, 4 cc. of BuOH and 17.5 cc. of 1:1 H_2SO_4, added to 9 g. of evapd. milk. The fat column was measured, as for condensed milk, from the bottom of the lower to the bottom of the upper meniscus. This method also yields accurate results when used on *ice cream* and ice cream mixes. C. R. FELLERS

Sterilization of glass-lined tanks. F. M. SCALES AND HARRIET E. RUSSELL. *Food Ind.* 3, 120–1(1931).—Results indicate that glass-lined tanks which have been properly cleaned and rinsed and then sprayed with a Cl soln. contg. 225–250 p. p. m. of available Cl in an alk. NaOCl soln. will be sterile or nearly so 30 min. after being sprayed. Bacterial cultures obtained from non-sterile milk bottles were used in carrying on the expts. C. R. FELLERS

Advances in processing aid domestic casein. F. L. CHAPPELL. *Food Ind.* 3, 102–4 (1931).—Approx. 60,000,000 lb. of casein, 80% of which is consumed by the paper

trades, is annually consumed in the U. S. A casein low in both ash and acidity is required. A continuous process of manuf. from skim milk is described. Briefly, the casein is pptd. by HCl, the concn. being approx. 0.5%, at a temp. of 43°. The curd is broken up, washed, pressed and dried to 10–15% moisture content within a very few min. The quality of the domestic product is constantly being improved. C. R. FELLERS

Bacterial flora of some ice cream ingredients. R. W. NEWMAN AND A. E. REYNOLDS. Calif. Dept. Agr., *Monthly Bull.* 19, 677–83(1930).—Data are given for frozen egg yolks, fresh eggs, powd. eggs, powd. skim milk, gelatin, sugar, powd. cocoa, cold pack (frozen) strawberries and ice cream colors. C. R. FELLERS

Gelatin percentage can be reduced. E. O. ANDERSON, T. A. LYONS AND R. L. PIERCE. *Ice Cream Trade J.* 26, No. 11, 81–3(1930).—Ice cream of good body was secured with the grade of gelatin used when the precentage of gelatin was about 0.10% and the homogenizing pressure was 3000 lb. Apparently satisfactory ice cream contg. no gelatin was also obtained when the homogenizing pressure was 3500 and 4000 lb. By taking advantage of these data com. ice cream is now being prepd. in which the gelatin has been reduced to 0.10%. A. H. JOHNSON

Gelatin will not be replaced. B. E. HORRALL. *Ice Cream Trade J.* 26, No. 11, 80–1(1930).—Expts. were conducted in which it was attempted to replace gelatin in the ice cream mix by using high homogenization pressures. The results indicated that the lots with higher gelatin contents and lower homogenizing pressures were not so coarse or icy as lots with lower gelatin contents and higher homogenizing pressures. The smoothness in texture of the ice cream increased with the quantity of gelatin used. Water showed a tendency to drain out of mixes contg. the smaller quantities of gelatin. The lower the gelatin content of the mix the shorter was the time required to reach the desired overrun. In general, the work indicated that high homogenizing pressure would not entirely replace gelatin. A. H. JOHNSON

Consistency of Swedish butter. E. HAGLUND, G. WODE AND T. OLSSON. *Kgl. Landtbruks-Akad. Handl. Tid.* 69, 1147–72(1930).—The consistency of Swedish butter at different times of the year and from various districts, and factors causing these differences, were detd. The no. of samples was 413. Butter hardness was detd. by the Perkins method (*C. A.* 8, 1313) at 15°, av. of 6 impressions, expressed as the wt. in g. which the falling body must have for the rod to displace 1 cc. of butter. The I value of the butter was detd. also. Butter hardness varies considerably with the time of year, and that from different districts at the same time of year is different. These variations are caused by variations in I value of the fat and hence are due to feeding. Hardness decreases as I value increases. Fat with a given I value can give butter with varying degrees of hardness. Churning tests showed that permanent variations in butter hardness can be produced by manuf. methods. Long cooling of cream before churning increases butter hardness, as does long cooling of butter granules before working. Differences in degrees of butter hardness caused by methods of prepn. are as great as variations in hardness of collected samples of identical I value. E. M. SYMMES

A new relation for the determination of vegetable oils in butter. OSCAR DE SOUZA VIEIRA. *Rev. brasil. chim.* 2, 237–46(1930).—Taking into consideration the increasing use of babassú oil and other palmaceous oils in the adulteration of butter and paying particular attention to the relative meanings of the various indexes, S. V. studies the methods actually used for the discovery of such fraudulent mixts. Bromometry is not yet suited to the study of small quantities of vegetable oils. A valuable relation results from the great differences between the consts. of the insol. fatty acids (Polenske) and butyric and caproic acids (xylene) in various kinds of vegetable oils, principally palmaceous oils. Thus the relation (Polenske/xylene) × 100 is found to be 10 for the various kinds of butters and possibly 1529 for babassú oil. JOHN M. LADINO

Effect of method of preparation on the calcium content and consistency of cheese. GUNNAR WODE. *Kgl. Landtbruks-Akad. Handl. Tid.* 69, 1032–43; *Medd. Centralanstalt. försöksväsendet jordbruks., Mejeriförsök* No. 40, 14 pp.(1930).—There is a close relation between Ca content and body of cheese; the higher the Ca content the weaker the body, and vice versa. During cheese making the vat whey dissolves Ca from the curd. A loss of Ca is caused also by the whey removed during the pressing. The quantity of Ca dissolved from the curd by the vat whey increases, parallel to the acidity of the milk before setting. If the vat whey is sepd. quickly from the curd it dissolves less Ca. The quantity of Ca dissolved from cheese by press whey increases with increasing vol. and acidity of press whey. The total Ca dissolved by vat whey is considerably greater than that dissolved by the press whey. E. M. SYMMES

Bleaching, muddy discoloration and black-spot development in colored cheese.

G. F. V. MORGAN. *New Zealand J. Agr.* **42**, 35–6(1931); cf. *C. A.* **25**, 748.—Bleaching of annatto-colored cheese was traced to the reducing action of certain organisms, including *B. subtilis* and *B. fluorescens liquefaciens*, on the dye in the absence of an adequate supply of atm. O. Upon longer keeping the bleached areas acquired a muddy discoloration. Black discoloration was traced to the action of bacteria in reducing Pb salts present in the annatto coloring material. K. D. JACOB

Physicochemical investigations of vegetable juice. E. CANALS, J. CANAYE AND E. CABANES. *Bull. soc. chim. biol.* **12**, 1022–4(1930).—P, Ca, Mg, Na and K were detd. in the expressed juice and in the dialyzate from turnips, carrots, radishes, spinach, asparagus, peas, beets and 6 fruits. Practically all of the Na and K and over 90% of the P and Mg were removed by dialysis. Of the Ca 30–94% (av. 70) was removed. C. G. King

Maraschino cherries, their preparation and manufacture. E. H. WIEGAND AND D. E. BULLIS. *Glass Packer* **4**, 125–7, 134(1931); cf. *C. A.* **24**, 439.—For bleaching the raw unstemmed cherries (white sweet varieties) a soln. of 1.5% of SO_2 and 1.5% soln. of $Ca(OH)_2$ is used. The process is usually carried out in bbls. Excessive lime causes spoilage to occur from gas-forming and liquefying bacteria. Daily agitation of the bbls. is necessary to prevent the lime from settling out. The cherries keep practically indefinitely in this soln. The cherries are leached in cold water for about 20 hrs. to remove SO_2 and lime, stemmed and pitted, and finally dyed with erythrosin or mixts. of erythrosin and Ponceau in a slightly alk. soln. $NaHCO_3$ added at the rate of 7 oz. per bbl. is used to give proper reaction for dyeing. About 1 oz. of erythrosin per 100 lb. of liquid is used. The dye is set by acidifying with citric acid added at the rate of 1 lb. per 100 lb. of liquid. The cherries are now ready for the candying process, which consists of the gradual building up of a sirup concn. of 50–65% of sucrose. Oil of bitter almonds or BzH is universally used for flavoring purposes. Sterilization of the bottled product is carried out at a temp. of 180° for 25–30 min. C. R. FELLERS

Determination of formic acid in fruit juices. A. HANAK AND K. KÜRSCHNER. *Z. Untersuch. Lebensm.* **60**, 278–90(1930); cf. *C. A.* **24**, 4098.—Steam-distil with 0.3 g. of tartaric acid for 45 min. 10 cc. of the juice or 10 g. of the fruit sirup dild. to 20 cc.; the increase in the vol. in the distn. flask should not exceed 20 cc. Avoid overheating by the use of an asbestos shield and collect 400 cc. of distillate in just enough distd. water to cover the end of the adapter. Dil. the distillate to 500 cc., titrate 200 cc. of it and calc. the total free volatile acids. To 100 or 200 cc. of the distillate, according to the amt. of HCO_2H present, add the calcd. amt. of 0.5 *N* NaOH soln. required to neutralize the acidity, followed by 0.5–1.0 cc. in excess. Warm the mixt. for 10 min. to saponify any formic esters and then evap. with 0.2 g. of Na_2CO_3, without boiling, until 30 cc. remains. Add sufficient 0.2 *N* $KMnO_4$ (usually 3–5 cc.) so that an excess of 1–1.5 cc. is present. Oxidation is complete after 45–60 min.; then add 1 cc. of 10% $ZnSO_4$ soln. to flocculate any suspended matter, and dil. the soln. to 50 cc. and filter. Det. the excess of $KMnO_4$ colorimetrically by matching the color of 25 cc. of filtrate against that of a 0.2 *N* soln. of $KMnO_4$ in a colorimeter. The colorimetric method is sensitive to 0.1 cc. (equiv. to ±2.76 mg. of HCO_2H). The method gave accurate results on a variety of fruit juices. C. R. FELLERS

The manufacture of lime juice and its economic value. V. H. KULKARNI. *Poona Agr. Coll. Mag.* **22**, 88–92(1930).—The manuf. and preservation of lime juice in India are described. The yield of clear juice is about 40% of the wt. of the fruit. West Indian bottled lime juice contains about 5.6% citric acid while the av. Kagdi lime juice contains approx. 7.5%. K. D. JACOB

New method of enzymic clarification of unfermented apple juice. ZOLTAN I. KERTESZ. N. Y. State Agr. Expt., *Bull.* **589**, 3–10(1930).—A very active pectin-decompg. enzyme obtained from *Penicillium glaucum* is proposed as an agent for assisting in the clarification of apple cider. The enzyme can be prepd. from the mold in either solid or liquid form. The method of extn. is not given. Starches or proteins are not attacked by the enzyme prepn. in concns. of 0.5% acting at 55° for 10 hrs. The insol. matter which is formed by the decompn. of the pectin and is largely responsible for the cloudiness in cider is readily removed by filtration or centrifugation. The clear filtrate may be bottled and pasteurized for 20 min. at 76° without showing any change in flavor. In 1 test about 30% of the pectin was removed from cider by enzyme clarification. The method may have com. applications. C. R. FELLERS

Removal of spray residues from apples; a wax-solvent method. J. R. NELLER. *Ind. Eng. Chem.* **23**, 323–5(1931).—Winesap apples were dipped in various solvents to remove the exuded wax and the oil that had been added in the spray mixts. MeOH proved to be a desirable solvent and enabled the HCl wash effectively to remove arseni-

cal spray residues that could not be removed with HCl alone even when heated. The storage quality of the fruit was not impaired. Practical considerations of the method are discussed. J. R. NELLER

Composition of tomatoes and tomato products and the determination of water in these products. A. LEONHARD. *Z. Untersuch. Lebensm.* **60**, 185–95(1930).—The compn. of 34 samples of German and Italian tomato products is tabulated. After comparing the various methods of detg. dry solids in tomato products, L. prefers to det. the water directly by distn. with xylene. Place 5–10 g. of the well-mixed sample in an Al boat and dist. with 150 cc. of xylene in a 300-cc. Erlenmeyer flask on a sand bath. A delivery tube 350 mm. long, bent at an angle of 45°, leads into a vertical 150-cc. graduated receiver completely immersed in running water and closed except for a glass tube drawn out at 1 end to 2 mm. in diam. and inserted through a rubber stopper. The bottom of the receiver contains 1 cc. of 1:1 KOH soln., and 150 cc. should distil over in about 20 min. Remove any condensate from the delivery tube by application of a small flame, shake the contents of the receiver gently and read the vol. of the sepd. aq. layer after 2 hrs., deducting the 1 cc. of alkali originally present. Volatile oils are retained in the xylene. The results for dry matter were compared with those obtained by calcn. from the sp. gr. of the filtered aq. ext. In general, the dry solids obtained by the direct distn. method were 0.0–4.7% less than by the sp. gr. method; *i. e.*, the moisture results were probably a little high, especially for samples of the more liquid products. C. R. FELLERS

Converting wastes into profits. A study of what can be done with tomato pomace. EARL D. STEWART. *Food Ind.* **3**, 112–4(1931).—Tomato seeds contain approx. 18–20% of high-quality edible oil resembling cottonseed oil, solidifying pt. −9°. It contains about 45% olein and 34.2% linolein. Tomato pomace may be readily dried in a rotary air drier. The yield is 15 lb. per ton of tomatoes. The compn. is crude protein 21.0, crude fat 18.0, fiber 27.3, N-free ext. 24.9 and moisture 5.0%. The product is ground in a hammer mill. Although the taste is bitter, the product is suitable for *cattle feed*. Other products are considered briefly. C. R. FELLERS

Insect control in dried fruits. H. M. REED. *Food Ind.* **3**, 117–9(1931).—The use of cold storage, vacuum fumigation with CS_2 and CO_2, HCN, ethylene oxide and ethylene oxide-CCl_4 mixts. are advocated for preventing or destroying insect infestation in various dried fruits under varying conditions. C. R. FELLERS

Some properties of honey colloids and the removal of colloids from honey with bentonite. R. E. LOTHROP AND H. S. PAINE. *Ind. Eng. Chem.* **23**, 328–32(1931).—Honey samples contain 0.1–1% colloids, which exert a considerable influence on the properties of the honey. The particles have an isoelec. point at p_H 4.3, at which max. flocculation by diatomaceous earth and min. cataphoresis occur. Addn. of bentonite flocculates the colloids completely. K. V. THIMANN

Some organic acids in honey. E. K. NELSON AND H. H. MOTTERN. *Ind. Eng. Chem.* **23**, 335–6(1931).—The non-volatile acids were detd. by Hartmann and Hillig's method (*C. A.* **24**, 2208), the pptn. with $Pb(OAc)_4$ being checked with known mixts. of malic and citric acids in the presence of sucrose. Succinic acid is present in the more acid specimens. Volatile acids, mostly HOAc and HCO_2H, range from 0.01 to 0.05%, malic and citric up to 0.05 and 0.008%, resp. K. V. THIMANN

Ultra-violet absorption of honeys. J. STITZ AND J. KOCZKÁS. *Z. Untersuch. Lebensm.* **60**, 420–5(1930).—The Bunsen-Roscoe absorption extinction coeff. e is given in terms of the intensities of incident light I_o and transmitted light I, the concn. c, and the thickness of the layer of soln. examd. x by $(1/cx)\log(I_o/I)$. By means of the Judd-Lewis sector photometer and Hilger quartz spectrograph e was detd. for wave lengths λ of 5500 to 2350 A. U. from the measured values of $\log(I_o/I)$ with a relative error of ± 2.2%. A layer 1–4 cm. thick was used, the source of illumination being a W-Fe arc with electrodes 3 mm. apart in front of a 0.02-mm. slit. Absorption curves in which e is plotted as ordinate against λ, are shown for 6 varieties of genuine honey, a characteristic curve always being obtained with a sharp max. at 2700 A. U. corresponding with e = 0.13 to 0.145 for a 1-cm. layer of a 4.5–6.5% soln. Glucose, fructose and sucrose give higher absorption maxima than water but all are relatively low. For com. sucrose, e is slightly higher than in the pure product. Dextrin has a very high absorption at 2700–800 A. U. Addn. to honey of 22% of sucrose lowered e by 0.3. The total absorption of honey cannot be detd. from the individual absorptions of its sugar constituents alone, since the nature and concn. of the ash, coloring matter and proteins exert a considerable influence. C. R. FELLERS

Mushrooms should be packed in glass. C. G. HICKS. *Glass Container* **10**, No. 1, 8–9, 22(1930).—Darkening or oxidation of canned mushrooms is due solely to the

presence of O and not to the action of light. A weak citric acid brine is used in the prepn. to prevent darkening during the heat treatment, which varies from 30 to 45 min. at 240° F. C. R. FELLERS

Stem marrow kale fodder, its cultivation and yield. H. EDIN AND G. SUNDELIN. *Kgl. Landtbruks-Akad. Handl. Tid.* 69, 972–1013(1930).—Stem marrow kale has been used widely recently, but data on feed value, cultivation and yield are scarce and inadequate. The dry substance of fresh stem marrow kale is 11.5–15%. Leaves contain twice as much protein as the stalk, and considerable fat. The org. substance was crude protein 16.4, fat 3.1, fiber 18.5, N-free ext. 62.0 and true protein 10.9%. The org. substance was about 86% of the dry substance. Digestibility coeffs. of late harvested kale were crude protein 75, fat 66, fiber 48, N-free ext. 88, carbohydrates 81, org. matter 78 and true protein 67. Fresh stem marrow kale contains about 95 feed units per 100 kg. of org. matter, 7.5 kg. of digestible protein, and 68 starch equivs., whereas dried kale has 66 feed units. The numerical value is 87–91 for fresh kale and 76 for dried kale. For cattle feeding, grinding or cutting is unnecessary, but the milk may have the taste of kale. Sheep eat stem marrow kale, but coarse stalks must be crushed. Pigs eat leaves without grinding, then eat stalks later. For 50 kg. body wt., 5 kg. of kale per day may be fed pigs, but this fodder is not a fattener. Poultry will eat cut kale, as a supplementary, rich vitamin food. Detailed instructions for cultivation of stem marrow kale are given. E. M. SYMMES

The camelthorn (Acacia giraffae, Burch). J. S. HENKEL. *Rhodesia Agr. J.* 28, 71–3(1931).—The pods of camelthorn are eagerly eaten by elephants, giraffes and other wild animals in Africa. Their compn. is: H_2O 9.4, acid-sol. ash 3.3, ether ext. 1.6, fiber 31.0, crude protein 11.4, CaO 0.9, P_2O_5 0.24 and K_2O 1.3%. A. L. MEHRING

Experiments in spray residue removal (STREETER, *et al.*) 15. A study of arsenical residue on apples in Pennsylvania (HODGKISS, *et al.*) 15. Importance of microbiology [in study of milk and its products] (CAZI) 15. Life and work [on ice cream] of the late Professor A. C. Baer (BECKER) 2. Proteins of Indian foodstuffs (NARAYANA) 11D. Influence of neutral red on respiration [of bakers' yeast] (GEIGER-HUBER) 11D. Rust resistance in wheat (HANNA) 11D. The antagonistic substances formed during bacterial fermentation (KLEIN) 11C. Apparatus for pasteurizing milk or other liquids by "holding process" (U. S. pat. 1,792,328) 1. Vacuum tank and heated tube system for condensing milk or other liquid products (Brit. pat. 335,964) 1. Continuous process for sterilizing milk or other liquids under pressure (Brit. pat. 337,027) 1.

Concentrated milk industries (*New journal*). Published monthly by the Olsen Publishing Co., 501–15 Cherry St., Milwaukee, Wis. Vol. 1, No. 1, appeared in Sept., 1930.

Preserving food. FRITZ WALTER RAUTH and WILHELM SCHEFFER. Fr. 694,527, April 25, 1930. Packing materials for food are coated with a mixt. of glycerol, a colloid such as agar-agar and water.

Preserving foods. ERICH FREUND. Fr. 695,096, May 5, 1930. Foods are preserved by heating them in a soln. of agents, such as salts of open-chain hydroxy acids, which facilitate the swelling of the dried products. Examples are given of the use of Na lactate and gluconate.

Conserving foodstuffs. RICHARD WILLSTÄTTER. Ger. 513, 656, Jan. 22, 1929. Animal and vegetable foodstuff is conserved by addn. of not less than 0.004% vol. of HCN in closed vessels. Thus, meat is kept fresh for 6 weeks at 20° with 120 to 300 mg. HCN to 5 kg. of meat in a 100 l. vessel.

Vitamin food. LAURENT M. RAYBAUD. Fr. 694,443, July 24, 1929. The vitamins in germinated seeds, whole or ground, are preserved by a coating of sugar chocolate, etc.

Hydrolyzed protein products. CHARLES N. FREY (to Standard Brands, Inc.). Can. 308,910, Feb. 24, 1931. Hydrolyzed protein substances high in assimilable N are made by hydrolyzing a protein-contg. substance with H_2SO_4, neutralizing a portion of the H_2SO_4 with CaO, sepg. the ppt. and neutralizing a further portion of the acid with aq. NH_3.

Flour. METALLGES. A.-G. Fr. 694,666, April 29, 1930. Flour for cooking purposes is improved by adding to the flour or to the cereal before grinding, perphosphates up to 2.5% or more of the wt. of the flour, so that besides O for the bleaching, there remains in the phosphate an amt. of O sufficient to have a raising action on the flour during baking.

Dough-bleaching agents comprising bean flour, etc. D. VERON. Brit. 335,943, July 3, 1929. A dough-bleaching agent is prepd. by treating fresh untreated legumes contg. carotin-removing enzymes with a green malt infusion, drying the treated material at a low temp. and grinding. NH_4 or Ca phosphates (3%) may be added to the infusion before use or similar mineral salts may be added to the bean flour in larger proportion, to form a composite yeast food and bread improver. Cf. *C. A.* **24**, 1676.

Bread. OTTO GRAUL. Ger. 516,268, July 27, 1928. In the manuf. of bread of relatively low carbohydrate content by baking a mixt. of rye bran or groats with fresh wheat gluten, sterilized white of egg is added to the leaven.

Yeast product. CHARLES N. FREY, ELMER B. BROWN and COLGATE CRAIG (to Standard Brands, Inc.). Can. 308,908. Feb. 24, 1931. A food product is prepd. by heating a mixt. of 4 lbs. of yeast, 35 cc. of HCl (d. 1.19), 10 cc. of lactic acid (85%) and 2.5 cc. of phosphoric acid (85%), hydrolyzing the mass, sepg. the residue and evapg. the ext., neutralizing the excess of acid and admixing flavoring ingredients prior to the completion of the evapn.

Yeast product. CHARLES N. FREY, ELMER B. BROWN and COLGATE CRAIG (to Standard Brands, Inc.). Can. 308,909, Feb. 24, 1931. A food product is prepd. by heating a mixt. of 4 lbs. of yeast, 35 cc. of HCl (d. 1.19) and 23 cc. of lactic acid (85%), hydrolyzing the mass, sepg. the residue and evapg. the ext., the excess of the acids being neutralized prior to the completion of the evapn.

Yeast product. CHARLES N. FREY, ELMER B. BROWN and COLGATE CRAIG (to Standard Brands, Inc.). Can. 308,911, Feb. 24, 1931. A food product is prepd. by hydrolyzing 4 lbs. of compressed yeast with 40 cc. of HCl (d. 1.19) and 10 cc. of H_3PO_4 (85%) in an autoclave at 15–20 lb. pressure for 3 hrs. The ext. is sepd. and the residue evapd. to a pasty consistency of d. 1.4. The acidity may be neutralized with soda; a favorable final reaction is approx. neutrality to litmus.

Baking powder. WILLIAM E. STOKES and REGINALD A. WRIGHT (to Royal Baking Powder Co.). Can. 308,902, Feb. 24, 1931. A baking powder comprises $NaHCO_3$ 300, $Ca(H_2PO_4)_2$ 33, Na H pyrophosphate 405 and starch 262 parts.

Testing milk. N. GERBER'S CO., G. M. B. H. Ger. 516,423, April 15, 1928. To det. whether udder disease is affecting the compn. of the milk, samples from each of the four quarters of the udder are treated with an indicator, preferably bromothymol blue, and then compared one with another.

Ozonized acetone. CHEM. FAB. VON HEYDEN A.-G. (Georg Schroeter, inventor). Ger. 495,021, Nov. 18, 1927. A product contg. active O is prepd. by treating acetone with ozonized O or ozonized air until an acid reaction has developed. The product is useful as a *reagent for distinguishing boiled from unboiled milk*, since a drop of the product added to milk that has been treated with ext. of guaiacum wood or resin gives a blue color with raw milk but no color with boiled milk.

Apparatus for pasteurizing milk in bulk. CHARLES E. NORTH (to Creamery Package Mfg. Co.). U. S. 1,791,511, Feb. 10. Structural features.

Emulsifying apparatus suitable for use with milk and butter. L. S. RICHARDS, E. M. RICHARDS and CREMAC MARKETING CO., LTD. Brit. 335,949, April 4, 1929. Mech. features.

Apparatus and system of operation for continuous freezing of food materials such as ice cream. CLARENCE W. VOGT (to Vogt Instant Freezers, Inc.). U. S. 1,791,772–3–4, Feb. 10. Mech. features.

Butter and margarine. UNILEVER N. V. Fr. 694,770, April 30, 1930. Butter and margarine of good keeping qualities are made by bringing the H-ion concn. of the aq. constituent to above 5.

Margarine. J. D. RIEDEL-E. DE HAËN A.-G. Ger. 516,119, July 28, 1926. The incorporation of lecithin and other phosphatides into margarine is effected by dissolving

the phosphatides in oxidized or polymerized oils, and incorporating the soln. with the margarine. Thus, lecithin 1 part and an oxidized unsatd. oil 4 parts may be dissolved in ether, the soln. evapd. and the product incorporated into margarine.

Cheese. SWIFT & Co. Ger. 513,666, Jan. 6, 1925. Emulsified cheese is produced by treating the pulverized cheese with an emulsifying agent, sterilizing and finally emulsifying without heating.

Conserving meat, etc. OTTO SINDL. Ger. 513,716, Oct. 27, 1927. The meat, etc., is treated with the condensed products passing over from a wood distn. at about 400°, the tar oil, MeOH and acid having been removed.

Cake, pastry, etc. POMOSIN-WERKE G. M. B. H. Ger. 516,363, Nov. 2, 1929. The deterioration of cake, pastry, etc., into a dry and stale condition is retarded by thoroughly incorporating pectin into the cake, etc., mixt. Examples are given.

Jams, marmalade, etc. A. W. BEACH. Brit. 336,321, July 22, 1929. In making jams, marmalade, conserves, confectionery, etc., the sugar is added in the form of an aq. soln. (preferably contg. 40% or more sugar) obtained by lixiviation or diffusion treatment of the sugar beet, followed by concn. and purification and decolorization.

Tea extracts, etc. O. STROBACH and P. A. WICKMANN. Brit. 335,901, July 1, 1929. Tea leaves are treated with an org. solvent (such as petroleum ether, pentane, $CHCl_3$ or ether), the solvent is removed to leave a dark green paste, and from the latter the chlorophyll, fat and wax-like components are removed by treatment first with 70–80% alc. and then with a solvent such as petroleum ether, and a tea-aroma residue is obtained by distg. off the last-mentioned solvent. A fat, oil or wax may also be used as a solvent by allowing the tea leaves to stand with it for a sufficiently long time. The tea paste may be dild. with sugar to deposit the tea aroma on the latter, and caffeine and tannic acid exts. may be added, prepd. from tea leaves remaining in the extn. app. Tablets may be prepd. from the product and it may be mixed with candy, chewing gum, milk or other edible substances.

Apparatus for drying tea. J. A. MAIN. Brit. 336,619, June 14, 1929. Structural features.

Alimentary salt. P. WOOG. Brit. 336,279, Feb. 18, 1929. Solns. contg. Mg salts are added to solid NaCl to give proportions similar to those of salts from sea water and the wet mixt. is dehydrated as described in Brit. 319,203 (*C. A.* **24**, 2513). Org. Mg salts may be used and some of the Mg may be in the form of insol. salts or finely divided or colloidal material.

Food for animals. R. A. LEGRENDRE. Brit. 336,014, Nov. 3, 1928. Preservation of feeds such as straw, bran or oats mixed with molasses is facilitated by adjusting the p_H of the contained moisture to a value between 6 and 11 by the addn. of various substances effective for this purpose.

Preserving green fodder. GUSTAV FINGERLING. Ger. 513,557, Nov. 20, 1925. Green fodder is treated with a Cl-evolving electrolyte, *e. g.*, NaCl soln. and subjected to electrolysis. The cathode is surrounded by a diaphragm. App. is described.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

European laboratories for the testing of materials. FRANKLIN L. EVERETT. *Mech. Eng.* **53**, 201–4(1931). E. H.

Drying the output of the chemical plant. RALPH BECKER. *Chem. Met. Eng.* **38**, 34–6(1931).—A survey of commercial drying equipment and applications. L. W. T. CUMMINGS

The heating and drying of granular materials by convection. W. GILBERT. *Engineer* **150**, 500–2, 530–2, 574–5, 617–9, 640–2(1930).—A study of the rate of heat transfer from hot gases to granular lumps of *coal, cement, clay*, etc., under varying conditions of lump size, gas velocity and gas temp. Graphs and formulas are given from which the rate of drying over a wide range of conditions can be calcd. D. B. DILL

The economy of hot-air drying with regard to the highest permissible temperature of the product to be dried. ÖDÖN VAJDA. *Chem. Fabrik* **1930**, 25–7; cf. *C. A.* **24**, 3066.—The results of calcns. of the heat consumption and power requirements for air circulation in parallel and counter-current driers and the lowering of the vapor pressure of hygroscopic materials as a function of the water content are shown on 4 charts. J. H. MOORE

Hydrogen in modern industry. RENE DUBRISAY. *Science ind.* 1929; 323–4. E. J. C.

Dust and air filtration. R. C. ROWE. *Can. Mining J.* **52**, 192–6(1931).—The advisability of filtering air for various machines is emphasized. Types of dusts and advantages gained by filtration are pointed out. The amount of filter surface is important. W. H. BOYNTON

The theory of rectification in packed columns. E. KIRSCHBAUM. *Chem. Fabrik* 1931, 38–40, 51–3, 63–5; cf. *C. A.* **24**, 4194.—A math. method is developed for calcg. the height and diam. of packed towers, which takes into account the phys. properties of the mixt. and quantities rectified. It has the advantages that in most cases the results may be obtained graphically, and a chart shows curves for detg. the height of intermittent and continuous towers. J. H. MOORE

Moisture in technical gases. II. Application of moisture calculations. FRIEDRICH LÜTH. *Arch. Eisenhüttenw.* **4**, 185–92(1930); cf. *C. A.* **24**, 2814.—After a discussion of the practical application of moisture calcns., various methods for measuring the moisture content of gases are described, among them the wet and dry bulb method, the pressure-temp. method, direct weight method and Haar hygrometer. H. STOERTZ

Chemical warfare. MICHELE GIUA. *Rivista chim. sci. ind.* **1**, 170–8, 193–201, 240–51, 266–72, 289–306, 321–60(1930).—Chem. and phys. properties, toxicity, uses and manuf. of poison gases used in the World War are described. E. M. SYMMES

Apparatus for defense against toxic gases. R. MARCILLE. *Compt. rend.* **192**, 382–4(1931).—The principle of the app. is as follows: respiration takes place in a closed bell; the expired air is passed into a soda soln. which absorbs the CO_2, the diminished vol. of air being supplemented by pure O from a small tank of compressed gas. Such an app. weighing 10 kg. maintains comfortable respiration for one person for 2 to 3 hrs. The app. is inexpensive and light in wt. and may also be made of sufficient size to protect several people at the same time. ALBERT L. RAWLINS

Chemical reactions in the oxygen isolation mask. ALBERT HLOCH. *Z. ges. Schiess-u. Sprengstoffw.* **25**, 379–81, 422–5(1930).—A discussion of the chem. reactions involved and the chem. problems to be solved in the design of a practical isolation-type gas mask. As fillers the alkali superoxides do not furnish sufficient O, and hence a small auxiliary O container is necessary. Other principal objections to this type of filler are: (1) the high temp. of the air entering the lungs and (2) the high breathing resistance of the canister. The alkali superoxides discussed are Na_2O_2, K_2O_4 and a mixt of the two, or $KNaO_3$. A newer type of filler contains alkali chlorates (cf. *C. A.* **24**, 5086). The reaction which furnishes O is started by a type of ignition which results in an initial burst of O which then continues at a rate sufficient for the needs of respiration. This filler is free from the objections cited against the alkali superoxide fillers. A. L. KIBLER

Burning accident from sodium chlorate. J. W. DEEM. *New Zealand J. Agr.* **42**, 55(1931).—Clothing worn during spraying with $NaClO_3$ for weed eradication should be washed free of all traces of the salt before being exposed to an open fire. In one case, failure to observe this precaution resulted in severe burns on the lower limbs. K. D. JACOB

Insulation for high temperatures. E. F. ZEINER. *Power* **73**, 104–6(1931).—Thermal conductivities of furnace-insulating materials and of insulating cements are compared. D. B. DILL

The thermal properties of ammoniates and analogous compounds and their use in absorption refrigerating machines (PLANK, VAHL) **2.** Heat transfer in liquid NH_3 (HIRSCH) **2.** Determination of the local strength of fabrics, felts, paper, etc. (SCHUBERT) **1.** Solid CO_2 from Mexico (MARTIN) **18.** Porous material for heat insulation, etc. (Brit. pat. 336,318) **18.**

Separation of gas mixtures. GES. FÜR LINDE'S EISMASCHINEN A.-G. ABT. GASVERFLUSSIGUNG. Ger. 513,683, Apr. 20, 1929. Addn. to 490,878 (*C. A.* 24, 2214) Gas mixts., such as air, are resolved into components by liquefaction and fractional evapn. in an app. such as described in 490,878, but in which the heat-exchangers and storers are modified. Cf. *C. A.* 24, 5117.

Gas reactions or purifications. COMPAGNIE INTERNATIONALE POUR LE FABRICATION DES ESSENCES ET PETROLES. Fr. 694,997, Aug. 2, 1929. In treating gases or vapors with catalytic or purifying agents a cylindrical or annular chamber closed at both ends is used, in which the catalyst or purifying agent is placed between 2 perforated partitions which allow a free space at each end for the gas. Perforated tubes for the admission of a reactivating agent and perforated tubes for the exit of the gases formed during the reactivation run through the mass parallel to the axis of the chamber.

Separation of dust from gases. WOODALL-DUCKHAM (1920), LTD., and A. M. DUCKHAM. Brit. 336,201, June 6, 1929. Sepn. of suspended matter from a gas, such as that resulting from the passage of air through a bed of coal and shale for stratification and removal of impurities, is facilitated by adding a gas or vapor such as steam or a liquid spray and so altering the relative ds. of the gas and dust and in some cases causing cohesion of the dust by wetting. Various details of procedure and control of the treatment are described, including an automatic control for the admission of the steam or other treating agent.

Separating fatty or waxy substances from solutions. DEUTSCHE GASOLIN A.-G. (Johann K. Pfaff, Kurt Böttger and Adolf Sieweke, inventors). Ger. 516,401, May 17, 1927. See Fr. 677,385 (*C. A.* 24, 3110).

Emulsions. DEUTSCHE HYDRIERWERKE A.-G. Ger. 513,813, Jan. 17, 1929. Addn. to 512,979 (*C. A.* 25, 1303). In emulsifying substances insol. or only slightly sol. in water, the emulsifying agent of 512,979 is replaced by the reaction products of the esters of monobasic org. acids and alcs. of high mol. wt., with polybasic org. acids. Thus, olein alc. is esterified with AcOH in the presence of H_3BO_3 and the product treated with adipic acid. The product is used to emulsify peanut oil or other neutral oils in the presence of a small quantity of NaOH. Another example is given.

Moistening pulverulent materials. OTTOKAR URBASCH. Austrian 120,160, June 15, 1930. A uniform and still pulverulent product is obtained by treating the materials with the vapor or spray of the moistening liquid in a rotary drum having loosed or fixed subdividing means. The treatment of stone dust, foundry sand, flue dust, fine ores and cement is referred to.

Separating lump materials according to their behavior toward rays of short wave length, including Röntgen, cathode or ultra-violet rays. FRIED. KRUPP GRUSONWERK A.-G. Ger. 516,130, July 27, 1927.

Sterilizing closed vessels. ARTHUR VONDRAN. Ger. 513,632, Mar. 27, 1928. A reversible air or gas current moistens and carries around the disinfecting agent.

Canister construction for breathing apparatus. R. H. DAVIS. Brit. 336,674, July 19, 1929.

Use of sodium peroxide and similar compounds in cartridges of respiration apparatus. DEUTSCHE GASGLÜHLICHT-AUER GES. and HANSEATISCHE APPARATEBAU GES. VORM. L. VON BREMEN & CO. Brit. 337,170, Nov. 7, 1928. In app. of this character, of closed-circuit type, evolution of O is effected at the commencement of breathing by the introduction into the app. of a gaseous acid such as CO_2 or HCl (which may be generated from an effervescent powder or supplied in suitable flasks). Various details of app. are described.

Refrigerating agents. K. BERGL. Brit. 336,557, June 11, 1929. In a refrigerat-

ing system employing in open circuit an aq. NH_3 soln., the NH_3 vapors are absorbed on exhaustion in a liquid such as H_2SO_4 which converts them into a non-volatile form. Various details of app. and operation are described.

Absorbent for use with ammonia in refrigerating apparatus. HARRY F. SMITH (to Frigidaire Corp.). U. S. 1,791,515, Feb. 10. A mixt. of $SrCl_2$ and $LiNO_3$ is used as an NH_3 absorbent.

Insulators. I. G. FARBENIND. A.-G. Fr. 694,151, April 18, 1930. Elec. conducting wires are insulated by filaments obtained by the hardening of polymerization, condensation or transformation products of butadiene hydrocarbons no longer elastic or extensible.

Insulators. I. G. FARBENIND. A.-G. Fr. 694,425, April 25, 1930. The condensation products obtained from ethers or thioethers of dicarboxylic acids and polyhydric alcs. described in Fr. 685,565 (*C. A.* **24**, 6041) are used as insulators in elec. machines and app.

Insulating material. GUSTAV OEDER. Fr. 694,644, April 28, 1930. A sound- and shock-insulating material is composed of a vulcanized oil mixed with MgO, cumar, etc.

Heat-insulating material. I. G. FARBENIND. A.-G. Brit. 336,163, March 11, 1929. See Fr. 691,068 (*C. A.* **25**, 1304).

Waterproofing materials and manufacture of electrical insulation. R. C. NEVILLE. Brit. 336,731, Aug. 29, 1929. Articles such as those of asbestos, asbestos cement, clay or the like are impregnated with coal tar, tar oil, pitch or similar material, dried and immersed in a soln. of CH_2O and phenol, and finally heated to 230° for 3–12 hrs. Various details and modifications of procedure are described.

Heat- and sound-insulation. M. CASES. Brit. 336,440, Oct. 24, 1928. The residue of the combustion of rice chaff is used (suitably in the proportion of 50% or more) with other materials such as asbestos, "silicate wool" and a small proportion of binding substances such as starch or fused silicates, or with clay and granulated cork, etc. Cf. *C. A.* **24**, 5087.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Potable and industrial water 1924–1929. Advances, processes, literature. H. BACH. *Chem.-Ztg.* **55**, No. 17, *Fortschrittsber.* No. 1, 1–29(1931). E. H.

Water supply conditions at Sweetwater, Texas. H. N. ROBERTS. *Proc. 12th Texas Water-Works Short School* 27–30; *U. S. Pub. Health Eng. Abstracts* **11**, W, 15(Jan. 31, 1931).—The new Bitter Creek supply of $2^1/_2$ million gals. per day plus a ground supply of 2 million gals. furnishes water of good quality for 11,000 people. Rapid filtration is used. C. R. FELLERS

Water works of the City of Mexico. EDUARDO MELINA, ANTONIO CORNEJO AND ALFONSO V. ACOSTA. *Southwest Water-Works J.* June, **1930**, 11–7; *U. S. Pub. Health Eng. Abstracts* **11**, W, 7(Jan. 24, 1931).—The source of the water is at Xochimilco Springs, about 20 miles south of the city. Because of previous occasional contamination, a dosage of 0.1 p. p. m. of Cl is now added. The present supply is to be enlarged to a capacity of 100 million gals. per day. C. R. FELLERS

Development of ground water supplies. R. O. JOSLYN. *5th Ann. Rept. Missouri Water and Sewerage Conf.*, 64–71; *U. S. Pub. Health Abstracts* **11**, W, 15(Jan. 31, 1931).—Of 200 water supplies in Missouri, 66% use ground water as a source. Drilled wells are more economical and less likely to become contaminated than dug wells. Complete sealing out of water from contaminated or otherwise unfavorable strata is essential. C. R. FELLERS

Analysis of the water and deposits from the springs of the "baths of Basna" (district of Tarnava-Mica). J. DICK. *Bul. soc. stiinte Cluj* **5**, 330–43(1930).—Analytical data are given. J. H. REEDY

The nitrogenous compounds in sea water—methods for their study. J. GIRAL. *Rev. acad. ciencias Madrid* [2], **25**, No. 10, 203–19(1930).—Attention is called to the wide variety of types of nitrogeneous compds. present in sea water. A review is given of the existing methods which might be applied to the study of the following classes of N compds.: free N, NH_3, nitrites, nitrates, albumins, total N and org. N compds. other than those mentioned. No exptl. data are given and no new methods are suggested. JOHN B. ENTRIKIN

The Hardershof water-purification plant at Königsberg. G. SATTLER AND R.

BRUCHE. *Gas u. Wasserfach* **74**, 73–6, 101–4, 128–32(1931).—A new water-purification system was constructed at the Hardershof waterworks of Königsberg in 1929 and 1930, and details of the system and its operation are given, with numerous illustrations. The yellow raw water is softened with lime water and clarified and decolorized by adding 30–60 mg. alum per l., followed by rapid filtration through a quartz-sand filter after a settling period. The older slow sand filtration plant is still in use. Daily detns. of color, hardness, free CO_2, p_H and permanganate requirement are made before, during and after treatment. Bacterial tests also are made. A clear and almost colorless water is obtained from the badly colored ground water. R. W. RYAN

An interesting water-purification change. OTTO REGEL AND ALBERT WICKLEIN. *Chem. App.* **17**, 207–8(1930).—A summary of changes made in a soda-lime water-softening system and the results obtained are given, including costs. M. C. ROGERS

Sterilization of water by metals. F. DIENERT AND P. ETRILLARD. *Compt. rend.* **192**, 185–7(1931); cf. *Compt. rend.* **136**, 707(1903); Lakhovsky, **188**, 1069(1929).—Previous work has shown the efficiency of Ag, Zn and Mg in destroying the microorganisms in water. The expts. here reported show that water is freed from *B. coli*, pathogenic organisms, and liquefying bacteria by passing it over a prepn. called silver sand or by agitating it with the silver sand. The organisms disappear more rapidly from water at 37° than at a lower temp. The presence of NaCl in the water retards the process of bacterial destruction. It is shown that water thus treated contains less than 0.003 mg. of Ag per l. N. M. NAYLOR

Experience with the lime-baryta process. A. FREDERKING. *Die Wärme* **53**, 943–9(1930).—The results of a no. of investigations on water-purification installations are presented. The effect of the addn. of lime and baryta, and the limit of softening are detd. ALLEN S. SMITH

Boiler-water conditioning. A Pittsburgh development. J. N. WELSH AND H. A. JACKSON. *Proc. Eng. Soc. West. Penn.* **46**, 327–42(1930); cf. *C. A.* **21**, 3407.—Success in boiler operation at high pressures depends upon the timely and correct analysis of the constantly changing boiler H_2O. Fundamental requirements of boiler H_2O conditioning establishes that a sufficient amt. of dissolved material (carbonate or phosphate) must be maintained to give chem. equilibria; all org. or saponifiable material must be eliminated and a min. concn. of solids in feed H_2O be maintained. Numerous specific examples, from the Pittsburgh area, of such conditioning are cited. EDWARD S. HOPKINS

Determining the quality of boiler-feed water by the electrical method. YU. M. KOSTRIKIN. *Izvestiya Teplotekh. Inst.* (*Trans. Thermo-Tech. Inst., Russia*) **1930**, No. 2, 27–32.—The performance of the Leeds-Northrup instrument of Philadelphia is described. A. A. BOEHTLINGK

Purification of sea water for boilers. I. SHIK AND G. TOROSYAN. *Azerbaidzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 10, 104–8.—Prevention of $CaSO_4$ formation is of primary importance. Ninety-five % of the Ca is pptd. by treating 100 cc. of water with 0.317 g. Na_2CO_3. Fair results are obtained even with 0.075% Na_2CO_3. V. KALICHEVSKY

The study of the fouling of steam turbine paddles. JULES ERNOULD. *Chaleur et Ind.* **11**, 178–80(1930).—Two 4500-kw. turbines running on steam at 14–15 kg. at 320° suddenly gave trouble after some years of satisfactory performance, by blade fouling in 2 weeks so that the rotor was quite out of balance. Two analyses of the deposits are given, the major constituents being CO_2, CaO, Fe_2O_3 and SiO_2. It was concluded that the trouble was due to the boiler feed waters. Finally this was held at 40–45° of alky., *i. e.*, about 2 g. per l. Some discussion is given as to how the deposits arose and also a description of the kind of corrosion seen in the steel tubes of water reheaters. S. L. B. ETHERTON

Practical operation of sewage works. C. E. KEEFER, *et al. Civil Eng.* **1**, 91–4 (1930).—This is a committee report and subsequent discussion before the Sanitary Eng. Div. Amer. Soc. Civil Eng. The report is a general review of sewage-plant operation and outlines principles for proper procedure. The detailed tests for control purpose are given together with suggestions as to the reporting of cost data, etc. The discussion, showing wide variance in personal opinion, was based upon the value of the various detns. and their relationship to the problems in question. EDWARD S. HOPKINS

The simple facts about sewage treatment. GEO. G. NASMITH. *Can. Pub. Health J.* **22**, 70–6(1931).—A discussion of sewage treatment, with particular reference to the North Toronto activated-sludge plant, which treats a normal dry-weather flow of about 4 million gallons per day from a residential district of 56,000 people. The plant consists of a storm-water tank, bar screens, primary settling tanks, aeration tanks in which rising air bubbles give the sewage a spiral motion, final settling tanks, sludge-digestion

tanks and glass-covered drying beds. The effluent is non-putrescible and contains 15–20 p. p. m. suspended matter, its quality being better than that of the Don River, into which it flows. The primary and activated sludges are continuously digested together, the 30,000 cu. ft. of gas collected being employed for heating the incoming sludge and for lab. purposes. Digestion is complete in a month. The digested sludge contains 50% org. matter and approx. 3% N_2, and is odorless. R. E. THOMPSON

Sewage-reclamation plant for Los Angeles. R. F. GOUDEY. *West. Construction News* **5**, 519–25(1930); *U. S. Pub. Health Eng. Abstracts* **11**, S, 10(Jan. 17, 1931).—In order to study sewage reclamation, the City of Los Angeles placed in operation in May, 1930, an exptl. sewage plant of 200,000-gal.-per-day capacity. The problems to be studied are outlined. C. R. FELLERS

Modified form of Imhoff tank used in four Oklahoma towns. FRANK B. KING. *Eng. News-Record* **106**, 112(1931).—General practice of allowing 15–20% of top area for gas vents is probably satisfactory where there is daily supervision or mech. means is employed to break up the scum, but experience has indicated that a greater area must be allowed for gas vents in installations where little attention is paid to operation. In modified type of tank employed in 4 towns in Oklahoma, 60% of the top is left for scum accumulation, the sludge bed being placed nearby to allow the scum to be thrown from the tank with a fork when excessive amts. interfere with escape of the gas. R. E. T.

Thermophilic digestion of sewage solids. IV. Fresh solids and activated sludge. WILLEM RUDOLFS AND H. HEUKELEKIAN. *Ind. Eng. Chem.* **23**, 67–9(1931); cf. *C. A.* **25**, 157.—Digestion of lab. samples of daily addns. of fresh and activated sewage solids was accomplished at 50° in the short period of 2.1 days, seeding materials produced under similar thermophilic conditions having been used. These expts. indicate that a daily charge of 50% volatile matter as fresh sludge can be assimilated. The sludge so obtained had all of the characteristics of well-digested material. Additional work is to be conducted on a semi-plant scale. EDWARD S. HOPKINS

Dewatering sewage sludge on glass-covered sand beds. G. C. HOUSER. *Munic. Sanit.* **2**, 69–70(1931).—Glass-covered beds afford means of at least partially controlling odors from drying sludge. By protecting the sludge from rain the area can be reduced as much as 50%. G. L. KELSO

Separate sludge-digestion plant at Toledo mechanically operated throughout. HARVEY P. JONES. *Eng. News-Record* **106**, 389–92(1931).—A description is given of what is stated to be the world's largest mechanically operated sep. sludge-digestion plant, now under construction at Toledo, Ohio. Treatment will include prechlorination, coarse screening, grit removal, sedimentation, sep. sludge digestion and sludge drying Mech. equipment will provide for automatic cleaning of coarse screens, continuous cleaning of grit chambers, continuous sludge removal from sedimentation tanks, skimming of scum and oil from the latter, and agitation of sludge during digestion. The plant, which is the final step in a 14-year program for cleaning up the Maumee River, is designed to serve the 1950 population of 600,000, contributing a mean daily flow of 80 million gallons. Prechlorination will be employed to eliminate odors and reduce the bacterial load, the chlorination plant being designed for an ultimate capacity of 18,000 lb. of Cl_2 per day, equiv. to a dosage of 15 p. p. m. based on the max. dry-weather flow of 140 million gallons per day anticipated in 1950. The screenings will be destroyed at the municipal incineration plant. Digestion tank capacity equiv. to 2.23 cu. ft. per capita will be provided, including 6 months' sludge storage during the winter. The gas formed will be collected in domes and utilized for maintaining the optimum digestion temp. Provision is also being made for maintaining the p_H value of the sludge at the optimum for digestion. The drying beds will be glass-covered, the space provided being equiv. to 0.25 sq. ft. per capita. The dried sludge will be used for reclaiming low-lying ground. The cost of the plant was estd. at $1,971,000 and the actual bids were approx. 5% lower. R. E. THOMPSON

The influence of chlorine on an activated-sludge process. H. D. BELL. *The Surveyor* **79**, 217–8(1931); cf. *C. A.* **24**, 1450.—Since bleaching powder is cheaper than liquid Cl for small plants, it was used to reduce the load on the bio-aeration unit. Twenty % increase in plant capacity resulted from chlorination. The final effluent showed an av. of 2.0 p. p. m. of nitrate N, thus showing that putrefaction was decreased by Cl treatment. A. L. ELDER

Filtering materials for trickling filters. WM. E. STANLEY. *Civil Eng.* **1**, 113–6 (1930); cf. *C. A.* **25**, 368.—A general review of the materials used in sewage filter beds. EDWARD S. HOPKINS

Selecting the materials to prevent clogging. FRANK W. JONES. *Civil Eng.* **1**, 118–20(1930).—The size and durability of filter-bed material must be such as to insure

an abundant air supply through the entire mass. Surface growths seal the beds, diminish the air supply and cause "ponding." This is also caused by application of improperly treated sewage. Disintegration of the beds may cause clogging in the depths, decreasing the voids. This may also be caused by the rough surfaces of the aggregates retaining the solids. Uniform particles of clean material should be used, regardless of size. They must be as durable as possible to retard disintegration by weathering. EDWARD S. HOPKINS

Operating filters to remove organic growths. CHAS. C. HOMMON. *Civil Eng.* **1**, 116–8(1930).—Study of about 60 sewage trickling-filter beds in this country shows that while reasonably clean filters are obtained naturally it is doubtful if the process is satisfactory. The uncertain natural removal of clogged material by sloughing, entirely beyond the control of plant operators, is a disquieting feature of plant control. Control of sloughing and killing of surface algae was accomplished by drying the beds for 24 hrs. every 7 days. This eliminated "ponding" and cleaned the top 12 in. of material of adhering particles by action of the sewage flow when re-admitted to them. The results of this practice in the Canton, O., plant were in accordance with expectation and prevented the more or less periodic "ponding" of the beds. EDWARD S. HOPKINS

Experiments on the destruction of the filter fly (Psychoda). W. D. SCOULLER AND H. H. GOLDTHORPE. *The Surveyor* 79, 219–20(1931).—Expts. were made on 2 filters with cresote-oil emulsion and *o*-dichlorobenzene. Expts. in l. cylinders showed that vapors from *o*-dichlorobenzene killed the flies in 10 min. Treatment on filters at the rate of 1 gallon per day per 437 sq. yds. of filter surface inhibited breeding of *Psychoda* after 10 days' treatment and gave immunity for a month. It was twice as effective as the creosote emulsion in paraffin oil. One gallon of creosote emulsion per day was needed per 220 sq. yds. of filter surface. Flies gradually returned when the treatment was stopped. A. L. ELDER

Notes on the determination of biochemical oxygen demand. W. D. HATFIELD AND K. MORKERT. *Sewage Works J.* **2**, 521–8(1930).—The diln. method was found to be accurate to 5% if the bottles were carefully cleaned with cleaning soln., rinsed and dried, and if the org. matter in the diln. water was well stabilized and the water itself not toxic to the normal bacterial flora. Distd. water for diln. gave low results, 500 p. p. m., bicarbonate water higher results, and natural well water still higher results. Adoption is recommended of a standard diln. water contg. Ca, Mg, Na, HCO_3, SO_4 and Cl ions. Data are given which show that rubber stoppers have an O demand and should never be substituted for glass stoppers in the incubation bottles. W. D. HATFIELD

Effect of sunlight and green organisms on reaeration of streams. WILLEM RUDOLFS AND H. HEUKELEKIAN. *Ind. Eng. Chem.* **23**, 75–8(1931); cf. *C. A.* **23**, 4760.—This lab. study is based upon the dissolved O, biochem. O demand and *B. coli* tests of samples collected from the Delaware River for 24-hr. periods. Results, presented in chart form, indicate that the dissolved O increased rapidly during the forenoon, reaching a max. between noon and 4 P. M. During the night a decrease was noted until the lowest point was reached at 3 A. M., with a subsequent increase again after daylight. This occurred in spite of temp. decrease during the night hrs. Many expts. confirm the belief that this O is given off by blue-green algae growths in vigorous activity. These data have important bearing on stream-pollution surveys, particularly in summer seasons and discredits afternoon sampling if these specimens of algae are present. EDWARD S. HOPKINS

Technic of stream-pollution investigations. F. W. MOHLMAN, T. L. HERRICK AND H. GLADYS SWOPE. *Ind. Eng. Chem.* **23**, 209–13(1931).—Special considerations are to be noted in the sampling of a polluted river. A carefully chosen sampling program is to be followed and the most representative points in the stream used for the testing stations. Bottom samples should be carefully collected to assure the elimination of sludge deposits. Composite samples are a necessity for correct data. Interesting diagrams locating proper sampling stations are given. EDWARD S. HOPKINS

Experimental studies of natural purification in polluted waters. IV. Influence of he plankton in the biochemical oxidation of organic matter. C. T. BUTTERFIELD, W. C. PURDY AND E. J. THERIAULT. *U. S. Pub. Health Repts.* **46**, 393–426(1931); cf. *C. A.* **24**, 2220.—A dil. dextrose-peptone soln. (I), which could be readily and accurately reproduced, was used in a series of expts. designed to show the functions of the bacteria and the plankton and the probable interrelationships of the 2 groups of organisms in the biochem. oxidation process. The results obtained in these expts. indicated that: Dil. I preserved free from biol. activity did not absorb any dissolved O under the conditions of these tests. (2) When inoculated with bacteria in pure culture, dil. I favored their growth, and they increased rapidly in no., reaching a limiting population on the second day of incubation. This limiting no. was maintained for long periods of

time. (3) While bacteria were actively multiplying, O was depleted at a rapid rate. After the limiting no. had been reached, this depletion of dissolved O practically ceased, although the living bacterial population remained high. (4) The results observed with mixed cultures of bacteria, free from plankton, were the same as with pure cultures, except that the extent of oxidation was somewhat greater. (5) The protozoön *Colpidium* grew well in the presence of bacteria in dil. I but was not able to grow in it in the absence of bacteria. When the concn. of food in the medium was increased 100–1000 fold, *Colpidium* grew well in the absence of bacteria. The conclusion was reached that in the dil. medium the bacteria act as "collectors" or "concentrators" of the *Colpidium* food. (6) *Colpidium* growing in pure culture used up the O. The amt. of O used, however, was comparatively small. (7) When bacteria and plankton were grown together in dil. I, the results obtained during the first 2 days of incubation were approx. the same as when bacteria only were present. After the first 2 days, however, the bacterial nos. were not maintained but were reduced rapidly, the reduction being accompanied by a plankton increase. Moreover, the oxidation process did not cease but continued as in natural polluted waters. (8) In general the extent of oxidation observed in dil. I varied directly with the complexity of the biol. factors present—that is, the greater the variety of organisms acting in the medium, the more extensive the O depletion observed. Based on the results obtained, the theory is advanced that the chief function of certain plankton in the biochem. oxidation process is to keep the bacterial population reduced below the satn. point and thus to provide conditions suitable for continuous bacterial multiplication, this in turn resulting in more complete oxidation. Support is given to this theory by the results obtained in expts in which the limiting nos. of bacteria were reduced by phys. and chem. means. Such reductions in bacterial nos. were invariably followed by renewed bacterial multiplication and oxidation. J. A. KENNEDY

Some inter-relationships of plankton and bacteria in natural purification of polluted water. C. T. BUTTERFIELD AND W. C. PURDY. *Ind. Eng. Chem.* **23**, 213–8 (1931); cf. *C. A.* **22**, 2223.—Normal polluted H_2O contains many bacteria and plankton, if these are removed or killed oxidation ceases. Studies with *B. aerogenes* and bacteria free *Colpidium* in pure culture were undertaken to show the relationship between them. Active multiplication of bacteria caused rapid adsorption of O by the H_2O until a limiting concn. was reached. Use of the pure plankton culture gave moderate O depletion, admixt. of the cultures gave rapid O adsorption during periods of bacterial multiplication and also after the limiting value of *Colpidium* had been reached. This indicates that the function of plankton in polluted streams is to maintain the bacterial population below their limiting value and to provide suitable conditions for their multiplication, thereby giving more complete oxidation. EDWARD S. HOPKINS

A routine method for direct determination of B. coli in large quantities of water on a solid medium. F. DIENERT AND P. ETRILLARD. *Ann. services Tech. hyg. Ville de Paris* **1930**.—In France the common test for *B. coli* is by the use of 0.1% phenol broth. The medium described is a type of eosin methylene blue agar. It contains: 1000 ml. distd. water; 10 g. peptone (Difco); 2 g. dipotassium phosphate; 10 g. lactose; 15 g. agar. The reaction is adjusted to p_H 7.5. When ready to use the following is added to 25 ml. of the agar: eosin yellow 2%, 0.5 ml.; methylene blue 0.5%, 0.5 ml.; phenol 5%, 0.25 ml. Highly contaminated waters are plated directly in small quantities. In waters less densely polluted the bacteria must be concd. *B. coli* colonies are round, and 3–4 mm. in diam. By transmitted light the center of the colony is a dark violet-blue, this color covering at least ¾ of their area. The periphery is bright gray blue, sometimes metallic in appearance. By reflected light the center of the colony appears slightly elevated. The colonies beneath the surface are in the form of small, dark-blue lentils. *B. aerogenes* colonies are 4–6 mm. in diam. with deep-brown centers when viewed by transmitted light. By reflected light they do not show the metallic sheen. In case of doubt colonies are picked and inoculated to peptone broth. G. L. KELSO

Epidemic of intestinal disorders in Charleston, W. Va., occurring simultaneously with unprecedented water-supply conditions. E. S. TISDALE. *Am. J. Pub. Health* **21**, 198–200(1931).—Throughout the entire drought period of 4 mos. (Aug. to Dec., 1930), in which acute and offensive taste and odor conditions existed in the water supply and a high pollution continued as a result of pollution of the Elk River by water from the Kanawha River, the filtration-plant operation was above reproach, and daily independent bacteriol. tests by 3 different water-testing labs. showed that the U. S. Treasury Standards had been met. The illness caused by these unprecedented circumstances is described. J. A. KENNEDY

Water-borne typhoid fever still a menace. ABEL WOLMAN AND ARTHUR E. GORMAN. *Am. J. Pub. Health* **21**, 115–29(1931).—W. and G. give a detailed analysis of water-

borne outbreaks of typhoid fever and *dysentery* covering the decade 1920–1929 for both the United States (47 states) and Canada (6 provinces). These outbreaks are classified as to population groups affected, as to points of pollution in waterworks system, as to causes and as to relative magnitude. Data are given concerning the largest outbreaks. The 5 cities in the U. S. with repeat outbreaks from the same cause and the 4 cities with repeat outbreaks from a different cause are further considered in tabular form.

J. A. KENNEDY

Use of chloramine in treatment of pool water. J. F. T. BERLINER. *Beach and Pool Mag.* **5**, 9–10(1931).—Chloramine, unlike chlorine, is not destroyed by org. matter or actinic rays, nor removed by aeration. Less chlorine is required, a reduction as high as 80% being accomplished. Complaints of tastes, odor, and irritating effects, as well as algae and slime growths are reduced. The ammonia is added before the chlorine. Before applying the *o*-tolidine test, nitrites, if present, must be destroyed by oxidation with H_2O_2.

G. L. KELSO

Chloramine, its preparation, properties and use (HIRSCHKIND) **6**. Importance of microbiology [in study of sewage and water] (CAZI) **15**. Apparatus for drying sludge for fertilizer (U. S. pat 1,792,064) **1**. Recovering fibers from the waste waters of the paper, cellulose, etc., industries (Austrian pat. 120,610) **23**. Apparatus for eliminating CO from motor-vehicle exhaust gases (U. S. pat. 1,791,912) **1**. Purifying light oils recovered from coal gas, etc. [with production of solutions for softening water] (Brit. pat. 336,636) **22**.

Regenerating zeolites used in water softening. WALTER H. GREEN (to Permutit Co.). U. S. 1,792,220, Feb. 10. A moving stream of the zeolite is first subjected to the action of a relatively weak regenerating soln and then to the action of a stronger regenerating soln. App. is described.

Tubular heat-exchange apparatus suitable for heating boiler feed water, etc. FOSTER WHEELER CORP. Brit. 336,899, Jan. 23, 1930 Structural features.

Dechlorinating water. JOSEF MUCHKA. Austrian 120,119, June 15, 1930. In removing excess of Cl from chlorinated water by passing the water through active C or the like, the dechlorinating mass is kept sterile by continuously exposing a fresh surface to the chlorinated water. Suitably, the water is supplied through an injector to the top of a container for the active C, and the water-supply pipe is connected to the bottom of the container in such a way that C is sucked up by the injector and carried by the water to the top of the C mass.

Rotary sewage distributor. E. HARTLEY. Brit. 336,384, Sept. 23, 1929. Structural features.

Purifying waste waters from gas manufacture. HEINRICH BRUNS. Ger. 516,527, July 25, 1929. Addn. to 504,337 (*C. A.* **24**, 5404). The washing oils required for the method of Ger. 504,337 are used in a cycle and are dephenolized, *e. g.*, by washing with NaOH soln., immediately before or after treating the waters therewith.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER AND M. S. ANDERSON

The formation of a board of specialists to study the interesting scientific problems of agriculture in the hot countries and the organization of scientific service for the Colonies. AUG. CHEVALIER. *Bull agr. Congo Belge* **21**, 365–73(1930).—The formation of a board to study the agricultural and forestry possibilities of the hot countries and to furnish scientific information is discussed. A no. of the important problems facing such a comm. are given.

J. R. ADAMS

Importance of microbiology as a subject of study and research in agricultural colleges. A. K. B. CAZI. *Poona Agr. Coll. Mag.* **22**, 172–9(1930).—The importance of microbiology in the study of *soils, manure, sewage, water* and, particularly, *milk and its products* is discussed.

K. D. JACOB

A few impressions of agricultural chemistry in foreign countries. C. A. BROWNE. *J. Assoc. Official Agr. Chem.* **14**, 101–12(1931).—An address dealing briefly with modern trends in European countries, as observed in the course of 16 months' sojourn in various European countries.

A. PAPINEAU-COUTURE

The restoration of the fertility of tropical soils. ALBERT BRUNO. *Bull. agr. Congo Belge* **21**, 574–80(1930).—A no. of the plantations in the French colonies have

lost much of their fertility because of lack of fertilization. Conclusions are drawn from work carried out in other countries as to the proper fertilizer for the various tropical crops on these plantations. J. R. ADAMS

Titanium in some New Zealand soils and pastures. H. O. ASKEW. *New Zealand J. Sci. Tech.* **12**, 173–9(1930).—Soils of various types from different regions were examd. The Ti content varied from 0.25 to 1.5%, calcd. as Ti, but in a large proportion of the samples it fell between 0.3 and 0.7%. "Bush-sick" soils, both of granitic and volcanic origin, were low in Ti. Heavy loam and clay were highest. The variation in Ti content of the pasture grasses and clovers is considerable. From 1 to 8.5 mg. TiO_2 per 100 g. dry matter was found. This amt. is believed to be too small to affect detrimentally the assimilation of phosphates in the animal body by pptn. of an insol. phosphate. There appears to be a correlation between the Fe and Ti contents of the pasture vegetation; both tend to increase at the same time. No correlation exists between Ti and Mn. L. E. GILSON

Chemical composition of the soils of McHenry County. T. H. HOPPER AND H. L. WALSTER. N. Dak. Agr. Expt. Sta., *Bull.* **240**, 3–46(1930).—The soils are carefully classified as to type, depth and chem. compn. The following composite % compn. of surface soils is representative: N 0.247, P 0.060, K 1.35, Ca 1.66, Mg 0.55, S 0.91, Si 35.22, org. C 2.72, carbonate C 0.24. With the exception of the gravelly and sandy soils, sufficient Ca, S, N, P and K were present for normal crop needs. C. R. F.

Chemical analyses of Congo soils. F. CLAUS. *Bull. agr. Congo Belge* **21**, 560–1 (1930).—A short note is given on the history of the analyses of Congo soils with the titles of a few of the publications on this subject. J. R. ADAMS

Chemical analyses of Congo soils at the Zambi Laboratory. G. BATZ. *Bull. agr Congo Belge* **21**, 562–6(1931).—Both the mech. and chem. analyses of 30 representative soil samples of the colonies are tabulated. The soils of the central basin are very mediocre in nutritive values while in the rest of the colony these values are variable and depend on the origin of the soils. J. R. ADAMS

Response of Illinois soils to systems of soil treatment. F. C. BAUER. Ill. Agr. Expt. Sta., *Bull.* **362**, 437–514(1930).—This bulletin brings together in summarized form, certain results obtained from 28 exptl. fields that are located on representative types of Ill. soils and have been under investigation for 15–26 years. The immature, dark soils of Ill. are much more productive than the mature lighter soils. Farm manure with or without lime was an effective fertilizer on all soil types. The proper use of lime is fundamental to the management of most Ill. farm lands, and nearly always gives very profitable returns. In general, soils deficient in available P respond generously to applications of superphosphate or very finely ground raw rock phosphate. Little difference was found as to the effectiveness of these 2 carriers of P. The light-colored soils and the less-productive dark-colored soils respond strikingly to applications of K. C. R. FELLERS

Microbiological studies of some typical Iowa soil profiles. P. E. BROWN AND T. H. BENTON. Iowa Agr. Expt. Sta., *Research Bull.*, No. **132**, 363–420(1930).—The nos. of bacteria, actinomycetes and molds in various horizons of typical profiles of some Iowa soils were detd. during 2 seasons, and the results are compared with careful descriptions of the soil profiles by horizons. C. R. FELLERS

Studies in soil colloids. I. Base exchange and soil acidity. AMAR N. PURI *Mem. Dept. Agr. India, Chem. Ser.* **11**, 1–38(1930); cf. *C. A.* **25**, 159.—The exptl. evidence obtained in this investigation lends support to the view that soil acidity is due to insol. colloidal acids or "acidoids," which are assocd. with surface-active H ions and characteristic reactions. A no. of reactions characteristic of sol. acids were studied in fully unsatd. soils obtained by exhaustive treatment with 0.05 *N* HCl. The results showed that acidoids, though insol., give reactions similar to those of sol. acids, the reactions taking place, however, in 3 distinct stages in which 1, 2 or 3 equivs. of H can take part. The exptl. facts can be best interpreted by supposing that the acidoid in a fully unsatd. soil is a tribasic acid. Results of liming expts. showed that toxicity of acid soils is confined to the primary H ion of the acidoid. **II. Factors influencing the dispersion of soil colloids in water.** *Ibid* 39–51.—Dispersion coeff. (D. C.) is defined as the % of the total clay (0.002 mm.) that can pass into suspension by "auto-subdivision" on being left in contact with water for 24 hrs. Expts. with air-dried clayic acid (obtained by prolonged treatment of clay with 0.05 *N* HCl) and metallic clayates (obtained by exhaustive treatment of clay with neutral salts) showed that Na clayates go almost completely into suspension after air-drying by simply keeping them in contact with water, while K, Ca and Ba clayates have a D. C. of approx. 10 or less. The D. C. for clayic acid and Al clayate is very low. Na and Li clayates contain the largest pro-

portion of particles that show no sign of settling to a depth below 5 cm. after 19 days. If a soil suspension at max. dispersion is converted, however, into any clayate (with the possible exception of the clayates of Al and Fe) the dispersion remains at its max., provided the soil is not allowed to become dry. Alkali soils rich in exchangeable Na show a high D. C. and a very low rate of percolation. Successive treatments of alkali soils with gypsum increase the permeability and lowers the D. C. Highly acid soils give a very low D. C. and a very high rate of percolation. Irrigated soils give a comparatively higher D. C. than unirrigated ones. **III. Flocculation of soil colloids.** *Ibid* 101–18.—Almost equiv. quantities of Ca, Ba and Sr hydroxides are required to flocculate a soil. The higher the valency of the exchangeable ion, the smaller the ionization and stability of the suspension and consequently the smaller the flocculation value (F. V.) for a given electrolyte. NaCl is an efficient flocculating agent when the exchangeable ions are principally Fe and Al, but is quite inefficient in the case of soils contg. principally exchangeable Na. In general, Na ions are the weakest flocculating agents, and they show a great difference between F. V. for partial and complete flocculation. Where the amt. of exchangeable Na is large, it is not possible to locate accurately the latter value because the whole mass gelatinizes. Flocculation values for Al ions are not greatly different from those for Ca and Ba ions. This is probably due to the formation of Na aluminates at higher p_H values, which behave like other Na salts as regards their flocculating power, or it may be due to pptn. of a part of the Al as $Al(OH)_3$. Mg ions are less powerful flocculating agents than Ba and Ca ions. The concn. of gypsum needed for flocculating a deflocculated soil contg. only bivalent exchangeable ions is 1.574 mg. of Ca per 100 cc. This shows that lime cannot function as a permanent cure for the deflocculated condition of a soil because the lime must be converted eventually into $CaCO_3$, a satd. soln. of which contains only 0.72 mg. of Ca per 100 cc. **IV. Methods of estimating soil colloids.** *Ibid* 119–31.—Methods of detg. soil colloids are briefly reviewed. Heat of wetting, dye adsorption and NH_3 absorption methods are affected by the nature of the exchangeable base in the soil and are not reliable measures of the colloid content. Mech. analysis and water-absorption methods seem to be the most accurate. It is suggested that the hygroscopicity of a soil should be measured by bringing it into equil. with an atm. of 70% humidity; and soil in equil. with an atm. of 10% humidity should be considered as dry basis for referring to hygroscopic moisture. In order to define completely the colloidal behavior of a soil it is necessary to know its clay content, hygroscopicity and base-exchange capacity. **V. Methods of determining saturation capacity and degree of saturation of soils.** *Ibid* 133–41.—The following method is proposed for detg. the state of satn. of soils with respect to bases: To 10 g. of the soil add 100 cc. of water and shake for 2 hrs. with 2 g. of $CaSO_4$. Next add 100 cc. of 0.2 *N* $Ba(OH)_2$ and shake at intervals for 6 hrs. during 2 days. After addn. of 10 drops of phenolphthalein soln. the color of the supernatant liquid is discharged with 0.1 *N* H_2SO_4 and the acid is then added gradually with vigorous shaking after each addn. The titration is complete when the supernatant liquid remains absolutely colorless for 2 hrs. The titration is completed in 2 to 3 days. The total $Ba(OH)_2$ minus the total acid gives the amt. of base retained by the soil and is equal to $T - S$, where T is the amt. of base the soil is capable of binding and S is the amt. of absorptively bound base originally present in the soil. T is detd. by washing another 10 g. of soil with 0.05 *N* HCl till all the replaceable bases are removed, as detd. by the absence of Ca ions in the filtrate, followed by washing with water till the free acid is removed. The soil is then transferred to a bottle and titrated with H_2SO_4 after addn. of an excess of $Ba(OH)_2$ exactly as described above. The method is simple and rapid, inasmuch as detns. can be made on 20 soils at one time.

K. D. Jacob

The adsorption of the anions of acid dyes by soil colloids. J. G. Smith and P. L. Gile. *J. Agr. Research* **41**, 401–13(1930).—Several soils contg. colloids with widely different silica-sesquioxide ratios were shaken with either H_2O or weakly acid solns. of the acid dyes, Na carminate, orange II and ponceau with negligible adsorption of the anions. The soils removed large quantities of ponceau from a 0.05 *N* acid soln. but this is evidently a pptn. of the dye.

J. R. Adams

A simplified method of determining "sticky point" of soils. Amar Nath Puri. *Agr. J. India* **25**, 206–9(1930).—The method of Keen and Coutts (*C. A.* **23**, 5261) for detg. the "sticky point" of soils is simplified as follows: 50 g. of air-dry soil is spread on a stout glass plate and water is added gradually from a buret. After each small addn. of water the soil is well mixed and worked into a paste, first with an Fe spatula and then with the hand, exactly as in the standard method. The sticky point generally can be located within 2–3 drops of water, corresponding to about 0.4 to 0.6% moisture content. The amt. of water in cc. multiplied by 2 gives the sticky point. On 48 samples of soil

from different parts of India, the results obtained by the simplified method were almost identical with those obtained by the method of Keen and Coutts if allowance was made for the air-dry moisture content in very hygroscopic soils. K. D. JACOB

Soil humus. S. OSUGI AND Y. SANO. *J. Sci. Soil and Manure; Proc. Intern. Soc. Soil Sci.* **5**, 112–3(1930).—Soil humus was fractionated by Waksman's method. The sol. portion is too small to be significant. The C, N and ash contents of the α- and β-fractions were examd. No particular relationships between the α-fractions of rich humus soils or the β-fractions in mineral soils were observed. Schollenberger's chromic acid method for detg. humus (*C. A.* **22**, 291) is satisfactory if samples of suitable size are used, *e. g.*, 0.01 g. sample of soil with 30% humus, 0.02 g. with 15.20% and 0.1 g. with 5%. B. C. A.

Potasssium thiocyanate method for determining soil acidity. Y. KAMOSITA. *J. Imp. Agr. Expt. Sta., Tokyo; Proc. Intern. Soc. Soil Sci.* **5**, 103–4(1930).—The color intensity in the Comber test for soil acidity was standardized by titrating the alc. ext. with KOH soln. Values so obtained for a no. of soils were compared with p_H values, exchange acidity and exchangeable base content. Soils exhibiting exchange acidity have $p_H < 5.5$. Soils with $p_H < 6.88$ give, with Comber's test, red colorations which increase in intensity with increasing exchange acidity. In soils showing exchange acidity the proportions of exchangeable Ca and Mg are smaller than those of Fe and Al. The reverse is the case where no exchange acidity exists. It is suggested that the red coloration in Comber's test is due to the exchange of ferric ions for K ions in the thio cyanate and that exchange acidity is partly the result of the presence of exchangeable Fe B. C. A.

The effect of lime on the texture of soils. WALTER REIMER. *Wiss. Arch. Landw.*, Abt. A., *Pflanze* **4**, 251–70(1930).—The heat of wetting of loam, clay or humus soils remains unchanged by addn. of CaO or $CaCO_3$. These substances increase the bacterial decompn. of org. matter in the soil, thereby changing the texture. This effect is negligible, however, for the quantities of CaO or $CaCO_3$ used in practice. W. G. R.

Lime additions to friable clay. W. BRENNER. *Bull. Agrogeol. Inst. Finland* No **29**, 13 pp.(1929); *Proc. Internat. Soc. Soil Sci.* **5**, 129–30(1930).—Addn. to soil of lime in quantities predetd. from titration curves to produce p_H changes up to 5.6 effected the calcd. changes. To bring about p_H 6 in the field, 1.6 times the quantity of lime calcd. from lab. tests was required. It was impossible in the field to bring the p_H value to 7.0. The most heavily limed areas of this soil rapidly developed further acidity. B. C. A.

The effect of plowing-under cane trash upon the available nitrogen of the soil. WM. L. OWEN AND W. P. DENSON. *Zentr. Bakt. Parasitenk.*, 2 Abt., **82**, 174–99(1930). The addn. of fresh cane trash to soils contg. nitrates causes a very rapid transformation of the N into org. forms. This depressing effect on soil nitrates decreases at a fairly const. rate when the crop residue is in contact with the soil, and under ordinary conditions it has perhaps lost most of its pernicious effects at the time the fertilizer is applied to cane fields. The addn. of fresh trash retards appreciably the rate of growth of corn plants but when it has been partially buried for several months, it increases the initial rate of growth and the yield. The addn. of cane trash to soil increases its water-holding capacity and retards drying. Cane trash in soil causes appreciable gains in total N, indicating stimulation of the N-fixing bacteria by the products arising from decompn of the org. matter. Field tests over a period of several years show no decrease in crop yields, indicating that the practice is consistent with conserving available N in the soil Whether the continued practice of incorporating such large quantities of org. matter with a C:N ration of approx. 1:40 would tend so to increase the accumulation of the more resistant constituent, lignin, as to affect unfavorably the compn. and productiveness of a soil needs further study. JOHN T. MYERS

Cellulose-decomposing soil-fungus of an unusual character. H. L. JENSEN *Proc. Linnean Soc., N. S. Wales* **55**, 699–707(1930).—A fungus, probably belonging to the genus *Botryosporium*, was isolated from an English field soil with addn. of manure. This organism proved very sensitive to acid reaction, p_H 4.5 being very near the limit of acidity at which growth could be induced; a good growth would only take place at p_H values above 6.0, and an optimum zone seemed to stretch from p_H 6.6 to p_H 7.4 and possibly higher. In neutral or alk. soln. the fungus exerted a very strong cellulose-decompg. activity; in unbuffered physiologically acid soln. it exerted almost no activity. Its sensitiveness to acidity is greater than that of any fungus hitherto studied. ALICE W. EPPERSON

Agreement between the Azotobacter and seedling plant methods (for determining the phosphoric acid requirements of soils). H. NIKLAS, H. POSCHENRIEDER AND F.

CZIBULKA. *Das Superphosphat* **6**, 111–5(1930); cf. *C. A.* **24**, 5410.—In 2000 comparative expts. with the *Azotobacter* and the Neubauer seedling plant methods for detg. the available P_2O_5 content of soils, the agreement between the 2 methods was very good, good and poor in 74.7, 14.1 and 11.2% of the trials, resp. K. D. JACOB

The evaluation of the results of soil analyses, with respect to the need of phosphate fertilization. ANTONIN NEMEC. *Wiss. Arch. Landw.*, Abt. A, *Pflanze* **4**, 228–46 (1930); cf. *C. A.* **24**, 5917.—Addn. of superphosphate to soils contg. but little phosphate sol. in 1% citric acid soln failed to increase the yield of sugar beets in some cases, whereas other cases were observed where increased yields were obtained from soils rich in phosphate sol. in 1% citric acid soln., when similarly fertilized. This anamolous behavior was found to be due to the Fe content of the soil. Soils contg. more than 45–50 mg. sol. Fe per 100 g. soil failed to show increased yields when fertilized with superphosphate, regardless of the phosphate content of the soil. Other expts. showed that the same effect is observed if the SiO_2 content of the soil is greater than 12 mg. per kg. soil. Similar results were found for several grains and vegetables. W. G. R.

Determination of easily soluble phosphoric acid and potash in soils by extraction with water and with carbonic acid-bicarbonate solutions. B. DIRKS AND F. SCHEFFER. *Das Superphosphat* **6**, 75–80(1930); cf. *C. A.* **25**, 1019.—It is proposed to det. easily sol. P_2O_5 and K_2O in acid soils by extn. with distd. water, and in neutral and alk. soils by extn. with a H_2CO_3 soln. of $Ca(HCO_3)_2$. Thirty g. of the soil is shaken with 75 cc. of water, or the soil is mixed with 1 g. of $CaCO_3$ and shaken with 75 cc. of soln. contg. CO_2 equiv. to 80 cc. of 0.1 *N* NaOH per 100 cc., for 1 hr. continuously in a 100-cc. flask. P_2O_5 in the filtrate is detd. by the Mo blue method, and K_2O is detd. by the cobaltinitrite method. The method gives results which usually parallel those obtained by the Neubauer seedling method, although the actual numerical values obtained by the 2 methods may be quite different. Results obtained with the method on soils receiving the same fertilizer treatment over a period of years are tabulated, and the use or non-use of P_2O_5 and K_2O fertilizers is definitely indicated by the data. K. D. JACOB

Increased root-solubility of potash contained in the soil as a result of phosphoric acid fertilization. C. DREYSPRING AND F. HEINRICH. *Superphosphate* **4**, 1–10, 46–59 (1931).—As a result of expts. with the Neubauer method for root-sol. K_2O and P_2O_5 on 85 soils of different types and origin, it was found that the root-soly. of the soil K_2O was increased 1 to 14 mg. per 100 g. of oven-dry soil by the addn. of P_2O_5 fertilizers. Readily sol. phosphates were more effective in increasing the root soly. of soil K_2O than were the less sol. phosphates. Superphosphate caused an av. increase of 8.8 mg. of root-sol. K_2O and basic slag an av. of 4.2 mg. per 100 g. of oven-dry soil. The percentage increase in the assimilation of K_2O, caused by either of the 2 phosphates, systematically diminished as the root-sol. K_2O content of the soil increased. The abs. assimilation by the plants, on the other hand, became slightly higher. The increase in the assimilation of K_2O was also dependent on the root-sol. P_2O_5 contained in the soil; the abs. figures became slightly, and the percentage figures considerably, smaller with increasing P_2O_5 content of the soil. D. and H. consider that the potash-activating power of superphosphate is due principally to its content of free H_3PO_4 and $CaH_4(PO_4)_2$. The Ca sulfate in superphosphate may also have some effect. K. D. JACOB

History of the ammonium citrate method for determining insoluble phosphoric acid. W. CATESBY JONES. *Am. Fertilizer* **73**, No. 11, 36, 38, 60(1930).—A review. W. H. ROSS

The fertility of the fundamental soil zones of the Union and their fertilizer requirements. A. N. LEBEDYANTZEV. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 351–63 (1930).—The soils were analyzed chemically for the properties which indicate to some degree the fertility of the soil, such as exchange capacity, exchange acidity, hydrolytic acidity, hygroscopic moisture, N, P, K and org. matter. The results are presented graphically and in tabular form on the podsols, gray forest soils, degraded chernozem, deep chernozem, ordinary chernozem, southern chernozem, chestnut and gray arid soils. The control pots of the vegetation expts., conducted by the Mitscherlich method, show that the natural fertility of the soil zones follows from a low point in the podsol zone to the highest point on the deep and ordinary chernozem and to a lower point on the southern chernozems and chestnut soils and still lower on the gray soils. The yields follow the properties of soil fertility enumerated above, which in themselves increase and decrease in the order of the soil zones as enumerated. The field expts., as well as some of the vegetation expts., indicate that all zones show deficiencies decreasing in the order N, P, K. The podsols have the least K. They also respond most effectively to fertilizers in general. The same is true for desert soils when water is supplied. Next in order of effective response are the northern chernozems. The lowest response is obtained on the

southern portion of the chernozem zone. Some specific crops require specific fertilizers irrespective of the soil zones. J. S. JOFFE

Survey of the fertilizer industry. P. E. HOWARD. U. S. Dept. of Agr., *Circ.* **129**, 1-22(1931).—A statistical review of the world consumption of N, P_2O_5 and K_2O; the world production of inorg. N compds., basic slag, superphosphate and other fertilizer materials; the quantity and value of fertilizer imports and exports for the U. S.; and the U. S. supply of N, P_2O_5 and K_2O. W. H. ROSS

Fertilizer trials at Rothamsted. Rothamsted Expt. Sta., *Rept.* **1929**, 125 pp.—Efficiency of phosphate fertilizers on grass land is in the order superphosphate > high-soly. basic slag > low-soly. basic slag > mineral phosphate. The high-soly. fertilizers increased the proportion of phosphate in the herbage. Superphosphate increased the potato crop provided no N was given, but decreased it in the presence of N and potash. In cooking tests the color of potatoes which had received potash fertilizers was superior. In this respect the chloride gave best results, followed, in order, by the sulfate and potash fertilizer salts. In flavor only the best of the potatoes fertilized with potash equaled that of the unfertilized; all others were inferior. Complete fertilizers gave best results with sugar beet, and these were still further improved by dressings of salt. With barley, H_2CN_2 and NH_4Cl again gave as good results as $(NH_4)_2SO_4$, though still inferior to $NaNO_3$. Potash reduced the attack of *Fusarium culmorum*. In pot culture chlorides delayed the ripening of barley straw and gave a lower dry-wt. yield than sulfates. The highest-quality barley was obtained with NH_4Cl and urea. No harm resulted from sowing up to 2 cwt. of H_2CN_2 per acre with the seed, but 4 cwt. per acre was distinctly injurious. B. C. A.

Nitrogen fertilizers. BRUNO WAESER. *Metallbörse* **20**, 1853(1930); cf. *C. A.* **25**, 1617.—A review of various pyrolytic and acid processes for making mixed fertilizers from phosphate rock and K Al silicates; from phosphate rock, HNO_3 and NH_3; and from KCl, H_3PO_4 and NH_3. S. L. MADORSKY

Results of experiments with nitrogen fertilizers on cotton. V. N. MANDRUGIN. *Udobreni i Urozhai* (*Fertilizers and Crops*) **2**, 363-9(1930).—The addn. of nitrogenous fertilizers from various sources at the time of planting shows that the best results during the year of application were from $(NH_4)_2SO_4$ followed by KNO_3, $CaCN_2$, NH_4NO_3 and $CO(NH_2)_2$. The best after-effects were shown by NH_4NO_3, followed by $(NH_4)_2SO_4$, KNO_3, $CO(NH_2)_2$ and $CaCN_2$. The highest total increase in yield for the 2 years came from $(NH_4)_2SO_4$ followed by NH_4NO_3, KNO_3, $CaCN_2$ and $CO(NH_2)_2$. When the same fertilizers were added during the process of boll formation the $CaCN_2$ was the most effective during the first and second years. In general, the increase in yield was higher when the fertilizers were added later in the process of growth. This is in accordance with the results of physiol. expts. which show that cotton takes up more N in the later stages of growth than during the early part. J. S. JOFFE

Nitrate fertilization and nitrogen fixation by the legumes. ERWIN WEBER. *Zentr. Bakt. Parasitenk.*, 2 Abt., **82**, 353-79(1930).—Nitrate fertilization decreases N fixation. JOHN T. MYERS

Potash fertilizers at the "Belle Etoile" distillery. DUBOSC. *Bull. agr. Congo Belge* **21**, 581-3(1930).—The addn. of a large quantity of K_2O causes a richer and purer juice in the sugar cane and favors the maturity of the cane. This in turn favors a greater production of rum to the acre of cane. J. R. A.

Tests with phosphate fertilizers. G. TOMMASI AND S. DOJMI. *Atti III congresso naz. chim. pura applicata* **1930**, 561-3.—In some cases the use of finely ground mineral phosphate is advantageous, but much less effective than sol. phosphate fertilizers. E. M. SYMMES

The use and action of phosphates on chernozem. M. A. EGOROV. *Pochvovedenie* (Russian) **23**, No. 3-4, 5-28(1928); cf. *C. A.* **24**, 2534.—In an attempt to establish the conditions for the reversion of phosphates in chernozem soils, E. conducted a series of expts. assuming beforehand that the Ca humates in the soil undergo double decompn. with sol. phosphates. By using the *mono-*, di- or tri-Na phosphate on soils the corresponding Ca phosphates ought to be obtained. Ten g. of soil was mixed with 50 cc. of 0.25 *N* solns. of various phosphates, shaken for 3 min. and filtered. With KH_2PO_4 the ext. was almost colorless; with NaH_2PO_4 the ext. was light yellowish brown; with $(NH_4)_2HPO_4$, K_2HPO_4 and Na_2HPO_4 it was the same; with K_3PO_4 it was dark brown; with Na_3PO_4 it was intense dark brown. Thus the color depends on the nature of the cation (Na being more active) and the anion ($H_2PO_4^-$ and HPO_4^{--} giving a slight coloring and PO_4^{---} producing an intense coloration). The intensity of the color increased with the increase in concn. and an increase in the time of shaking. The humus substances can be released by washing with a salt soln. and then with water. Exts.

obtained by the use of NaH_2PO_4, Na_2HPO_4 or KH_2PO_4 together with $CaCO_3$ are darker than those obtained with the phosphate alone. $CaCO_3$ alone when mixed with soil and water gives no humus in the ext. Five-g. samples of soil were treated with 25 cc. 1.0 *N* NaH_2PO_4, KH_2PO_4 and Na_2HPO_4, shaken for 3 min., placed in collodion bags and dialyzed. After a few days a brownish liquid began to rise from the surface of the settled soil in the bag with the NaH_2PO_4 and diffuse through the supernatant liquid. It finally turned the entire bag into a dark-colored mass; some org. matter started to go through the dialyzer. This action was slower with the Na_2HPO_4. With the KH_2PO_4 the liquid after 3 months was just a weak brownish yellow. The behavior of the NaH_2PO_4 and Na_2HPO_4 is explained on the basis of formation of the more sol. $Ca(H_2PO_4)_2$ and the less sol. $CaHPO_4$. Addns. of $FeSO_4$ or $FeCl_3$ to exts. of Na_2HPO_4 had no effect on the mobility of the humus. Addns. of $FeCO_3$ gave the same results as addns of $CaCO_3$. The reactions in all cases resolve themselves into the formation either of a sol. or an insol. phosphate. By successive extns. with Na_3PO_4 and decanting it was found possible to obtain in soln. most of the org. fraction of the absorbing complex, about $^1/_3$ to $^1/_2$ of the total org. matter is contained in this fraction. J. S. JOFFE

Fertilizing action of bone meal. E. TRUNINGER AND F. KELLER. *Landw. Jahrb. Schweiz.* **43**, 931–45(1929).—Bone meal, with preference for the defatted, is recommended to give good results when used on acid soil. One application of raw bone meal gave 0.33 the increase of superphosphate; on doubling the application the increase was 0.50. There is a relationship between the particle size and the activity. N from bone meal is estd. to be 50% as valuable as nitrate N. GEORGE R. GREENBANK

Ammonia liquor as a fertilizer. BIMSCHAS. *Gas u. Wasserfach* **74**, 13–6; *Gas Journal* **193**, 324(1931).—Pot tests carried out at the Mitscherlich Expt. Sta at Marienburg on the effect of NH_3 liquor on oats and mustard plants in light, medium and heavy soils indicate that good results may be obtained on the better or heavier soils Phosphate and potash were added in each case. In spite of the alk. nature of the NH_3 better results were obtained when phosphate was added as Thomas meal instead of superphosphate. This was first noted at a period about half-way in the growth of the plants and became more noticeable as the expt progressed Poor results were obtained on a pure sand soil, even though potash and phosphate were added. R. W. RYAN

Composition of lime for fertilizer. YOSHIZO HAYASHI. *J. Imp. Agr. Expt. Sta.* **1**, 57–72(1929).—The CaO content of 43 representative liming materials in Japan varied from 55.94 to 95.92%, av. 71.82%. The finer the particles of lime, the lower was the CaO content. K. KITSUTA

Production of citric-soluble fertilizers by the decomposition of phosphorite with silica at high temperatures. JAAK KUUSK. *Acta Commentationes Univ. Tartuensis* (Dorpatensis) **AXX**, 1, 1 79(1930)(in German).—A study was made of the optimum conditions for the formation of citric-sol phosphate (sol. in 2% citric acid soln.) by heating natural phosphates with SiO_2. With Esthonian phosphorite and Florida phosphate, both of which have the fluorapatite structure, active decompn. began at about 1370° and, in general, the percentage of citric-sol. P_2O_5 increased with further increase in temp. With finely ground phosphate, passing a sieve having 5000 meshes/sq. cm., the amt. of citric-sol. P_2O_5 formed depended upon the quantity of SiO_2 used, up to about 42% of the wt. of the furnace charge, and better decompn. was obtained with finely ground SiO_2, passing a sieve having 5000 meshes/sq. cm., than with the same wt. of coarse SiO_2. Approx. 90 to 98% of the total P_2O_5 was converted into the citric-sol. form when mixts. contg. 30 to 40% SiO_2 were heated rapidly in an internally fired gas furnace to 1380° and then heated to 1440–1460° at the rate of 2°/min. Lower results were obtained when the mixts. were heated in an elec. furnace under the same conditions. Phosphates contg. excessive amts. of lime were successfully decompd. by proportionately increasing the amt. of SiO_2 in the charge. The presence of more than about 10% of Fe_2O_3 and Al_2O_3 depressed the citric soly. of the P_2O_5. K. thinks that the citric-sol. P_2O_5 is present as a *silicophosphate*, $3Ca_3(PO_4)_2.CaSiO_3$, which results from the replacement by SiO_2 of the F in the fluorapatite compd., the F being volatilized as SiF_4. With phosphates of the carbonato-apatite type decompn. began at about 1100°, and above this temp. the percentage conversion in a given time increased rapidly. K. D. JACOB

Industrial value of marine flora. VICTOR DE BUEN. *Rev. ing. ind.* **1**, No. 6, 5–12; No. 8, 12–6(1930).—A brief review is given of methods of prepn. of fertilizers, I, alginic acid, cellulose, food products and other org. prepns. from various marine algae and phanerogams. L. E. GILSON

Field results indicate value of ammoniated superphosphate for cotton. ANON. *Phosphorus Digest*, Feb., **1931**, 2–6.—Complete mixts prepd. from KCl and highly

ammoniated superphosphate plus $(NH_4)_2SO_4$ (when additional N was required) were compared with mixts. of similar analysis prepd. from KCl, ordinary superphosphate and $(NH_4)_2SO_4$ as fertilizers for cotton in field tests carried out in S. C., Ga. and Ala. In 17 tests the ammoniated superphosphate mixts. gave an av. yield of seed cotton 6.4% greater than that obtained with the ordinary superphosphate mixts. The av. yield of cotton obtained at the first picking was also higher from the plots fertilized with the ammoniated superphosphate mixts. The ammoniated superphosphate used in these expts. was prepd. by treating ordinary superphosphate with approx. 6% of anhyd. NH_3.
K. D. JACOB

Effect of fertilizers on the phosphorus content of plants. J. H. MITCHELL. *Phosphorus Digest* March, 1931, 6–7.—Expts. by the S. C. Expt. Sta. over a no. of years showed that application of complete fertilizers contg. 10 12% P_2O_5 gave av. increases of 27, 42 and 47% in the P_2O_5 content of oats, soy beans and grass hay, resp.
K. D. JACOB

The present and the improved methods of making farmyard manure in Kanara. R. M. HEGDEKATTI. *Poona Agr. Coll. Mag.* **21**, 222–40(1930).—Large quantities of farmyard manure are prepd. in India by the fermentation in pits of org. materials in the presence of approx. 30% by wt. of cattle dung and urine. The principal org. materials used are the green and dry leaves and young shoots of forest plants. The leaves of a no. of varieties of plants used for this purpose contain approx. 1.10 to 2.10% N and 0.5 to 20% tannin as well as astringent resins and volatile oils which act as deterrents to injurious insects in the soil. Fermentation of the material in the pits is hastened by keeping it moist and turning it occasionally. Fermentation is also hastened by the addn. of 0.1% N in the form of $(NH_4)_2SO_4$ and 5% of lime or lime alone. A better grade of manure is produced in covered pits than in uncovered pits. In 7 expts. the loss of org. matter during fermentation ranged from 29.5 to 64%. Analyses of various org. materials and of manures prepd. from them are tabulated.
K. D. JACOB

Barnyard manure nitrification in cultivated fields. CHR. BARTHEL AND N. BLENGTSSON. *Kgl. Landtbruks-Akad. Handl. Tid.* **69**, 1014–31(1930). Expts. with pure bacterial, yeast and mold substance and different amino acids, show that N which is included as a constituent in the cell substance of different microorganisms, and which forms the main portion of the org. N in barnyard manure, is nitrified readily in the soil when it is present in the form of pure prepns. However, org. N in barnyard manure does not mineralize in tilled soil until a very long time has elapsed, and has no fertilizing effect during the first months or years after introduction. Either the microbial cells in the manure are protected from decompn. by colloidal substances in which they are imbedded, or the decompn. depends upon the C–N ratio (cf. Jensen, *C. A.* **23**, 5263). Data are insufficient to decide upon either theory.
E. M. SAMMIS

The conservation of ammonia in fertilizing with liquid manure. S. TOVBERG-JENSEN. *Wiss. Arch. Landw.*, Abt. A, *Pflanze* **3**, 161–80(1930). The rate of escape of NH_3 from solns. of $(NH_4)_2SO_4$ plus NaOH and NH_4HCO_3 was detd. by drawing air through the solns. maintained at const. temp. Lab. expts. were conducted on the rate of escape of NH_3 from liquid manure spread on various soils. The effect of added salts was detd. by adding $CaCl_2$, KNO_3, gypsum and superphosphates to the liquid manure, and detg. the NH_3 lost when the solns. were allowed to dry on filter papers. The lab. expts. show that the liquid manure is best spread on the soil when it is porous, in cool weather, and that addn. of the salts mentioned prevents 90% of the loss of N_2 ordinarily suffered. Field expts. were also conducted by fertilizing with (1) liquid manure, (2) KNO_3, $CaCl_2$ and superphosphate dissolved in liquid manure and (3) liquid manure and each of these salts added separately, the best results were obtained by dissolving the salts in the manure. The following *rapid volumetric method for the detn. of* NH_3 is described: The liquid manure is added to an alk. NaOBr soln. and the N_2 evolved is collected and measured in a gas buret. 100% of the N_2 in NH_3 is obtained by this method, but only 95% of the N_2 is liberated from urea.
W. GORDON ROSE

The use of preservatives to prevent loss of nitrogen from cow excreta during the day of collection. ROWLAND B. FRENCH. *J. Agr. Research* **41**, 503–6(1930).—Thorough mixing of the feces and urine greatly increases the speed of the action by which N is lost. When unmixed this loss is from 1 to 2.6% of the total N in 18 hrs. at 70° F. and when these excreta are thoroughly mixed it varies from 6 to 30%. $CuSO_4$, $ZnSO_4$ and formaldehyde in small concns. gave complete protection against loss of N when added to homogeneous mixts. of feces and urine but the $CuSO_4$ was very ineffective with unmixed excreta. At higher concns. boric acid, $FeSO_4$, phenol, salicylic acid and toluene also showed some preservative action.
J. R. ADAMS

The chemical composition of grass from plots fertilized and grazed intensively in

1929. J. G. ARCHIBALD. *J. Agr. Research* **41**, 491–501(1930).—The dry matter of the grass from the fertilized plots was higher in N, ether ext., Ca and P, and lower in crude fiber than the dry matter of the grass from the unfertilized plot. Acre production of all constituents detd., crude fiber excepted, was markedly higher on the fertilized than on the check plots. The seasonal variations in the compn. of the grass confirm the conclusions of a previous paper (cf. *C. A.* **23**, 4008). The amt. of rainfall is one of the most important factors which influence the chem. compn. of the grass. J. R. ADAMS

Club-root in cruciferous crops. J. G. GIBBS. *New Zealand J. Agr.* **42**, 1–17 (1931).—Fertilization of cruciferous plants with basic slag and K_2SO_4 seemed to reduce the intensity of club-root infection. Satisfactory control of the disease was obtained by applying burnt lime at the rate of 2 to 3 tons per acre about 3 months before sowing the crop. K. D. JACOB

Calcium relationships of forage crops. L. I. PUGSLEY AND R. R. MCKIBBIN. *Can. J. Research* **4**, 39–51(1931).—Samples of soil, timothy and red clover were secured from the Chateauguay River basin, Quebec, and analyzed to det. the cause of the variation in Ca content of clover and timothy previously observed. The Ca content of timothy and red clover increased directly with the total Ca content of the underlying soil and decreased as the "lime requirement" of the soils increased. No proportionate increase of protein or of P as the Ca content of the hays increased was observed. The timothy hays from the area investigated were extremely low in Ca content but otherwise normal. The ratios $\frac{CaO}{P_2O_5}$ and $\frac{\text{protein}}{CaO}$ for these hays are, resp., abnormally low and abnormally high. In the red-clover hays these values were normal. J. W. SHIPLEY

Nature and course of the nutrient intake of various vegetables. T. REMY AND F. WEISKE. *Landw. Jahrb.* **71**, 315–31(1930).—The rate of intake of a no of vegetables is studied by cultural trials. The significance of the cultural intake and growing period is considered in studying the proper fertilizer treatment and the appropriate fertilizer. GEORGE R. GREENBANK

Fertilization of cucumbers and strawberries with carbon dioxide gas. H. LUNDEGÅRDH. *Kgl. Landtbruks-Akad. Handl. Tid.* **69**, 1044–56(1930).—The theoretical basis of CO_2 fertilization has been investigated (Sveriges Tradgårdsodling Årsbok 1923), and practical tests with CO_2 fertilization on various hot-house plants have been made (Der Kreislauf der Kohlensaure in der Natur, Jena, 1924; Centralanst. f. försoksvas. på jordbruksomr., Medd. no. 331(1928)). Tests were repeated in hot houses, with alc. burned as the source of CO_2. A l of 95% alc. gives 6000 cal on burning and induces air currents for distribution. CO_2 fertilization increases the fruit no. and wt. of cucumbers 28.5–45%, with a CO_2 atm. 3–4 times normal. Lamps were filled every morning, lighted, and burned about 20 hrs. until extinguished spontaneously, then the dil. alc. residue was removed to avoid evapn. of denaturant. With strawberries, ripening was earlier, the fruit no. increased 12%, the wt. of fruit higher, and the leaf growth greater. A profit is shown by comparison of the alc. purchased *vs.* increased return from sale of cucumbers. E. M. SYMMES

Potato scab and fertilizers. EICHINGER. *Das Superphosphat* **7**, 8–14(1931).—Superphosphate and $(NH_4)_2SO_4$ have a decided effect in reducing scab on potatoes. Sulfate of potash-magnesia (a mixt. of K_2SO_4 and $MgSO_4$) and probably K_2SO_4 tend to reduce the occurrence of scab. KCl has no protective action, but seems to favor scab formation to a slight extent. Because of its alk. nature basic slag favors scab formation. Scab formation is promoted to a marked extent by $NaNO_3$ and to a less extent by $Ca(NO_3)_2$. K. D. JACOB

Preparations containing rotenone for use as insecticides. I. Aqueous suspensions. HOWARD A. JONES AND WILLIAM M. DAVIDSON. *J. Econ. Entomol.* **24**, 244–57 (1931).—Aq. suspensions of rotenone were prepd. by two methods: (1) Rotenone solns. in water-miscible solvents were added to water, and powdered prepns. were mixed with water. (2) Permanent suspensions contg. 0.05–0.5 g. rotenone per l. with the rotenone in highly dispersed condition were prepd. by the addn. to water of pyridine solns. and acetone solns. contg. tannic acid. Mixts. of certain dry products with pptd. rotenone also gave satisfactory suspensions. Permanent suspensions of rotenone were more easily obtained under slightly alk. conditions, but they were difficult to obtain in hard water. Toxicity expts. on various species of insects indicated that aq. suspensions of rotenone are of definite value in the control of certain types of insects. Rotenone decomposes rapidly in pyridine, less rapidly in acetone contg. tannic acid and very slowly in pure acetone soln. This decompn. is accompanied by a corresponding loss in toxicity (cf. following abstract). Pure dry rotenone shows no change in toxicity on standing. C. H. RICHARDSON

The toxicity of rotenone in solution and suspension. W. M. DAVIDSON AND HOWARD A. JONES. *J. Econ. Entomol.* **24**, 257–62(1931).—The loss in toxicity to insects of rotenone in pyridine solns. and acetone solns. contg. tannic acid is described. The pure acetone and alc. solns. of rotenone did not lose toxic activity upon standing. The yellow decompn. material obtained in a pyridine soln. of rotenone was much less toxic to insects and fish than pure rotenone. Aq. suspensions of rotenone made from fresh acetone and alc. stock solns. decreased in toxicity to insects upon standing. It is recommended that stock solns. of rotenone in pyridine and acetone be used immediately after prepn. Solns. in acetone and alc. may be allowed to stand a limited time without loss in toxicity. C. H. RICHARDSON

Some comparative tests with rotenone, nicotine and pyrethrum. MERRILL M. DARLEY. *J. Econ. Entomol.* **24**, 111–5(1931).—A soln. of rotenone (concn. 1:100,000) contg. a com. petroleum prepn. (concn. 1:200) compared favorably as a contact poison with nicotine at 1:10,000 and pyrethrum at 1:74,800 concn. the tests being made upon 2 species of aphids. Pyrethrins at 1:37,400 were effective against the spotted cucumber beetle (*Diabrotica duodecimpunctata*) and the Mexican bean beetle (*Epilachna corrupta*), but nicotine at 1:5000 and rotenone at 1:50,000 were ineffective. A com. petroleum prepn. at 1:100 was used in each spray. Tests indicated that the toxicity of rotenone for the common red spider (*Tetranychus telarius*) was appreciably greater than that of nicotine and pyrethrins. The relative toxicity of rotenone was greater for this animal than for the aphids. C. H. RICHARDSON

Genuine derris root may contain no rotenone. R. C. ROARK. *J. Econ. Entomol.* **24**, 328–30(1931).—Expts. have shown that rotenone is far superior in insecticidal value to deguelin, tephrosin and toxicarol, the other insecticidal constituents of derris. Therefore all the matter extd. with ether from derris root may not be equal to rotenone in toxicity. Numerous samples of root sold as derris root have recently been found to contain no rotenone. The rotenone content of derris root varies from 0 to 5.5%, whereas the total ether ext. ranges from 5 to 23%, there is no consistent relation between the two. The compn. of the ext. from derris root, *i. e.*, the ratio of one constituent to the other, also may vary considerably. A sample found to be rich in toxicarol entirely lacked rotenone. This lack of uniformity in proprietary derris prepns. accounts for many of the inconsistent results reported by entomologists. The common derris root now on the market may be expected to contain about 2% rotenone. Cubé root (*Lonchocarpus nicou*) from South America contains as much as 7.6% rotenone. An ext. of cubé root prepd. in Peru or Brazil may soon be placed on the American market. C. H. RICHARDSON

An insecticidal method for the estimation of kerosene extracts of pyrethrum. H. H. RICHARDSON. *J. Econ. Entomol.* **24**, 97–105(1931).—The speed with which pyrethrum exts. paralyze house flies (*Musca domestica*) varies directly with the concn. The speed of paralytic action is variable, but the variation falls within the limits of error due to random sampling. This was not true of the mortality after 24 hrs. Differences in speed of paralytic action between a 0.75 lb. (per gal.) and 1 lb. kerosene ext. of a fairly powerful grade of pyrethrum powder (0.26% pyrethrin I) were easily distinguishable and statistically significant. Differences in percentage mortality, analyzed similarly, were not significant. C. H. RICHARDSON

Problems in the manufacture of liquid household insecticides of the petroleum extract of pyrethrum type. ALFRED WEED. *J. Econ. Entomol.* **24**, 95–7(1931).—The problems which confront the manufacturer of pyrethrum products are: (1) the concn. of the toxic constituents to be used; (2) the use of pyrethrum powder or concd. exts. in prepg. the products; (3) the selection of satisfactory petroleum fractions and perfumes. C. H. RICHARDSON

The effect of soap on the toxicity of a pyrethrum product known as "Red Arrow." A. E. BADERTSCHER. *J. Econ. Entomol.* **24**, 268–77(1931).—This is a study of a com. mixt. contg. pyrethrum ext. with the addn. of K coconut fatty acid soap in various proportions. The green spiraea aphis (*Aphis spiraecola*) was used as the test insect. "Red Arrow" dild. with tap water does not give max. efficiency probably because the surface tension of the aq. carrier is too high to permit sufficient penetration into the trachea of the insect. The toxicity of this product is increased about 4 times when dild. with 0.4% soap, the surface tension of the aq. carrier then being nearly 30 dynes. "Red Arrow" loses little if any of its toxicity upon standing. C. H. RICHARDSON

Experiments with white oil-pyrethrum for the control of the oriental peach moth. BYRLEY F. DRIGGERS. *J. Econ. Entomol.* **24**, 319–25(1931); cf. *C. A.* **24**, 3313.—The newly hatched larvae of *Laspeyresia molesta* are killed more easily when crawling over sprayed new growth than when crawling over sprayed old growth, because of the great

absorptive power of the old growth for the oil. Reduction of fruit infestation amounted to 30–70%. The effects of parasites and their relation to spraying operations are discussed. C. H. RICHARDSON

Tests with nicotine activators. E. P. FELT AND S. W. BROMLEY. *J. Econ. Entomol.* **24**, 105–11(1931).—Field tests were carried out with nicotine solns. contg. various petroleum oil emulsions, Na oleate, K oleate, com. soap flakes and Ca caseinate prepns. The results indicate the influence of a complex of factors on the toxicity of the various mixts. C. H. RICHARDSON

Nicotine in the control of ectoparasites of poultry. F. C. BISHOPP AND R. D. WAGNER. *J. Econ. Entomol.* **24**, 56–62(1931).—The feather mite (*Liponyssus silviarum*) is controlled by treating roosts and spraying the houses with nicotine sulfate soln. The common chicken mite (*Dermanyssus gallinae*), the fowl tick (*Argas miniatus*) and the sticktight flea (*Echidnophaga gallinae*) are controlled by spraying poultry houses with strong solns. of nicotine sulfate. Fowls are treated for the various species of chicken lice by making a light application of nicotine sulfate (40%) to the upper surface of the perches ½ hr. before the fowls go to roost. With proper ventilation of poultry houses and correct dosage this method will not injure fowls. Disadvantages of the method are discussed. C. H. RICHARDSON

Comparative performance of nicotine tannate and lead arsenate against the codling moth. ROBERT S. FILMER. *J. Econ. Entomol.* **24**, 277–83(1931).—If a sufficient quantity is maintained upon the foliage during the period of codling moth activity nicotine tannate controls this insect as well as Pb arsenate. Nicotine tannate in appropriate concns. injures neither fruit nor foliage. In its present form nicotine tannate disappears rapidly from the foliage, 60–70% loss occurring in 10 days after application. Before it can be used as an efficient substitute for arsenicals its adhesive qualities must be improved. C. H. RICHARDSON

Report of committee to formulate plans for investigation of the codling moth from biologic and control standpoints. A. L. QUAINTANCE, LEROY CHILDS, G. A. DEAN, B. A. PORTER, P. J. PARROTT AND W. A. ROSS. *J. Econ. Entomol.* **24**, 18–23(1931).—Results of lab. and field tests from 25 Federal and State entomological labs. are given. The following insecticides are considered: Mn arsenate, Na_2SiF_6, $BaSiF_6$, K fluoaluminate, petroleum oil-nicotine mixt., petroleum oil-pyrethrum mixt., petroleum oil-Pb arsenate mixt., petroleum oil derris mixt., highly refined (white) petroleum oil emulsion, nicotine tannate and rotenone. Removal of As spray residue also is considered. Mech. control methods (banding, chemically treated bands, bait traps, soil treatment), use of parasites and biol. data are reported. C. H. RICHARDSON

The effect of hydrogen-ion concentration on the toxicity of nicotine, pyridine and methylpyrrolidine to mosquito larvae. CHARLES H. RICHARDSON AND HAROLD H. SHEPARD. *J. Agr. Research* **41**, 337–48(1930).—The toxicity of 0.03 *M* nicotine solns. to mosquitos increased with increasing p_H value, reaching a max. at p_H 9.7 (the free base). Similar results were obtained when either HCl or H_2SO_4 was used to adjust the p_H of the soln. At each nicotine concn. the free base was about 5 to 7 times more toxic than was nicotine sulfate soln. at p_H 5.0. The addn. of an inorg. hydroxide had no apparent effect upon the toxicity of a nicotine soln. Pyridine solns. of 0.03 *M* and 0.12 *M* were about twice as toxic as solns. of the same molar concn. titrated to p_H 5.0 and 4.9, resp., with H_2SO_4. Methylpyrrolidine soln. was about 19 times as toxic as methylpyrrolidine-HCl soln. of p_H 3.0. The toxicity of these materials in aq. soln. is directly related to the concn. of the undissocd. mols. The toxicity of nicotine solns. is largely dependent on the dissocn. of the pyrrolidine N. J. R. ADAMS

Trapping for the Japanese beetle (Popillia japonica Newman) during the seasons of 1929 and 1930. O. K. COURTNEY. *J. Econ. Entomol.* **24**, 219–26(1931).—The operation of traps with a bait mixt. contg. geraniol and eugenol is described. C. H RICHARDSON

The tolerance of beans to sprays and dusts for the Mexican bean beetle. H. C. HUCKETT. *J. Econ. Entomol.* **24**, 200–4(1931).—Further studies with com. brands of arsenicals, $BaSiF_6$ and cryolite in spray and dust mixts. against *Epilachna corrupta* indicate that certain forms of arsenicals cannot always be used with safety upon bean plants. Mg arsenate, $BaSiF_6$ and cryolite are the safest to use at recommended concns. C. H. RICHARDSON

Hints at new spraying procedures. P. J. PARROTT, F. Z. HARTZELL, HUGH GLASGOW AND S. W. HARMAN. *J. Econ. Entomol.* **24**, 297–302(1931); cf. *C. A.* **24**, 3312.—This investigation was conducted to find materials or practices that would amplify present control measures for the rosy aphis (*Anuraphis roseus*), and the eye-spotted bud moth (*Spilonota ocellana*) on apple trees. $NaNO_3$, one lb. per gal., made the trees unattractive

to rosy aphis without apparent injury to the trees. Fall applications of nicotine or ground tobacco to apple trees reduced the number of aphids. Tar distillate sprays were very effective against apple aphid eggs and nymphs of the spruce gall aphid (*Adalges abietis*) but were ineffective against eggs of the leaf roller. These tar distillate sprays appeared safe to use on the trees. American creosote oil emulsified with sulfonated castor oil and alkali killed eggs of the rosy aphis and caused no serious injury to the trees. Sulfonated fish oils apparently may be used in place of the sulfonated castor oil to reduce the cost of this spray. These methods may offer a marked advantage over spring spraying for control of the rosy aphis. C. H. RICHARDSON

A study of arsenical residue on apples in Pennsylvania with respect to efficient spraying practice. H. E. HODGKISS AND D. E. HALEY. *J. Econ. Entomol.* **24**, 83–8 (1931).—In Pa. protection of apples from second-brood larvae of the codling moth (*Carpocapsa pomonella*) requires a definite spray procedure ending early in June. In this way it is possible to control the insect with Pb arsenate and to keep the As residue within the export tolerance of 0.1 grain per lb. of apples. Analyses of fruit are given. C. H. RICHARDSON

What summer oil sprays may do to apple trees. JOSEPH M. GINSBURG. *J. Econ. Entomol.* **24**, 283–90(1931).—Refined (white) petroleum oils, viscosity 80–320° Saybolt at 100°F., and sperm oil were sprayed on apple and peach trees during the spring and summer months. The oils were emulsified with soap or powdered skim milk, and the emulsions dild. to contain 0.5 3% actual oil. Some trees were sprayed during two successive seasons and accumulative effects on the fruit and foliage were studied. Peach trees are less susceptible to petroleum oil injury than apple trees. Continuous oil spraying of apple trees during the growing season produced physiol. changes in growth processes and fruit production. Oil injury is more pronounced and more severe from early than from late spraying. Sperm oil was less injurious to peach and apple foliage than any of the other animal or vegetable oils tested. C. H. RICHARDSON

Experiments in spray residue removal. L. R. STREETER, P. J. CHAPMAN AND G. W. PEARCE. *J. Econ. Entomol.* **24**, 240–4(1931). —The standard washing machine using HCl as a solvent entirely and satisfactorily removes As residue. Methods successful in the Pacific Northwest are not entirely adaptable to the needs of the Northeast In the Northeast a machine is required which combines the washing and wiping principle. No single machine now available entirely meets these requirements. Results of chem. analysis of sprayed fruit are given. C. H. RICHARDSON

Investigations aimed to reduce the cost of pear psylla control. F. Z. HARTZELL. *J. Econ. Entomol.* **24**, 71–7(1931).—Economy can be obtained in part by modifying the environment of the orchard, by using lubricating oil emulsions, and by decreasing the concn. of nicotine in the sprays. Care must be exercised in the use of petroleum oil sprays on weak trees. C. H. RICHARDSON

The compatibility of lime with fluosilicates. R. H. CARTER. *J. Econ. Entomol.* **24**, 263–8(1931); cf. *C. A.* **24**, 455. —The compn. and chem. properties of fluosilicates in relation to insecticidal use and injury to foliage are described. The addn. of small quantities of $Ca(OH)_2$ to Na_2SiF_6, K_2SiF_6 and $BaSiF_6$ materially decreased the solv., probably because of the introduction of a common ion from the reactions. Strong alk. solns. were formed when an excess of lime was present as the result of further chem reactions. C. H. RICHARDSON

Mercury salts as disinfectants of seeds. VITTORIO CASABURI. *Industria chimica* **5**, 1362–8(1930); cf. *C. A.* **25**, 553.—By using an emulsion of 1,4-$Cl_2C_6H_4$ in petroleum taken up with talc in conjunction with Hg salts, a powerful disinfecting action is obtained, with a smaller quantity of Hg salts. A. W. CONTIERI

Tests with *p*-dichlorobenzene-oil emulsion against the San José scale. OLIVER I. SNAPP AND J. R. THOMSON. *J. Econ. Entomol.* **24**, 328(1931). – A petroleum oil of 168 sec. viscosity (Saybolt) and a volatility of 0.60% was used in these expts. *p*-$C_6H_4Cl_2$ was dissolved in it in the proportion of 2 lb. per gal. The oil was emulsified with K fish oil soap and the spray contained 0.25–1.5% actual oil. The addn. of *p*-$C_6H_4Cl_2$ to an oil does not increase its effectiveness for the control of San José scale. C. H. R.

The influence of plant growth on the activity of root bacteria (GRÄF) **11C.** Removal of spray residues from apples (NELLER) **12.** Burning accident from $NaClO_3$ (DEEM) **13.** Effect of various Mn compounds on the quinhydrone electrode (OSUGI, KASHIHARA) **2.** "Lime-nitrogen" (Brit. pat. 336,677) **18.** Apparatus for making lime-nitrogen (Ger. pat. 516,445) **18.** Dicalcium phosphate and KNO_3 (Brit. pat. 336,692) **18.** Purification of gases and the manufacture of fertilizers (Belg. pat. 371,622) **4.**

Fertilizer. C. VILAIN. Brit. 336,651, July 15, 1929. Natural dolomite is treated with H_3PO_4 and the product may be treated with NH_3.

Fertilizers. SOC. D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIM. Fr. 694,455, July 27, 1929. A compd. fertilizer is prepd. by treating natural chlorides with a strong mineral acid such as H_2SO_4, HNO_3 or H_3PO_4, isolating the K salt formed and using the liberated HCl to attack natural phosphates and mixing the sol. phosphate with the K salt. Cf. *C. A.* **25**, 1625.

Fertilizers. SOC. D'ÉTUDES SCIENTIFIQUES ET D'ENTREPRISES INDUSTRIELLES. Fr. 694,628, April 28, 1930. A fertilizer is composed of a mixt. of natural phosphates and blast-furnace or P-furnace slags.

Fertilizers. G. OBER & SONS CO. Fr. 694,113, April 17, 1930. Phosphatic fertilizers are made by sending a current of hot acid through a restricted receiving zone, mixing this current with a current of finely divided phosphatic material and sending the mixed current through the restricted receiving zone. The phosphatic powder may be aerated to render it more fluid. An app. is described. Fr. 694,114, describes the prepn. of a fertilizer by submitting a phosphatic material to the action of an acid in a closed vessel and afterward introducing NH_3 into the vessel. Fr. 694,115, describes the prepn. of a fertilizer by forming currents of acid and finely divided phosphatic material, mixing the currents, introducing the mixed current into a vessel and regulating the concn. of the acid current and the duration of the charging to reduce to a min. the losses of volatile substances during the transport.

Powdered deodorizer for accelerating the ripening of organic fertilizers. KAZUYOSHI YAMAJI. U. S. 1,791,918, Feb. 10. A cereal powder contg. a large quantity of enzymic material such as barley, wheat or beans is mixed with bran, water is added and the mixt. is heaped for fermentation, after which it is dried and powdered and mixed with dried and powdered germinated seeds of cereal such as barley, wheat or beans high in enzymic content and tri-Ca phosphate also is added to the mixt., which, as thus prepd., is suitable for treating org. fertilizer or use as a deodorant.

Insecticides. MAURICE BOURDERIONNET. Fr. 694,139, April 18, 1930. An insecticide and rat-killer is composed of a mixt. of HCN with 3–6% of oxalic acid and 2–5% of CNBr.

Insectifuges. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER. Ger. 516,373, Apr. 20, 1923. Pulverulent compns. for combating flea-beetles, etc., comprise a solid absorbent, *e. g.*, kieselguhr, mixed with nitrobenzene and a substance which repels the insects by its odor, *e. g.*, "oleum animale," phenol or cresol. Substances improving the adhesion, *e. g.*, talc, may be included.

Destroying insects and other animal pests. I. G. FARBENIND. A.-G. (Carl Taube and Hans Kukenthal, inventors). Ger. 516,496, Oct. 10, 1929. Esters of H_2SO_3 are used, alone or mixed with diluents, other insecticides, inflammability-reducing substances, etc.

Bactericides; fungicides. I. G. FARBENIND. A.-G. (Rudolf Lehmann and Richard Michel, inventors). Ger. 516,485, Nov. 23, 1928. Mixts. of halophenols (or their derivs.) with esters of substituted aromatic carboxylic acids are used, with or without other disinfectants, etc. A mixt. of trichlorophenol acetate 1 and methyl *p*-hydroxybenzoate 3 parts is specified.

Plant-protecting agents. I. G. FARBENIND. A.-G. Ger. 513,775, Dec. 6, 1927. The agent consists of hydrocarbons of the diaryl type, combined with other fungicides or insecticides and optionally mixed with solvent, adhesive or spreading agents. The examples mention biphenyl, 4,4'-dichlorobiphenyl, 2,2'-diaminobiphenyl and dinitrobiphenyl.

Mordants for seeds. I. G. FARBENIND. A.-G. Fr. 694,994, May 5, 1930. Mordants for seeds are composed of thio derivs. of alkylarsenious acids such as methylarsine sulfide, or the condensation product of methylarsine and β-thionaphthol, arsenomethane and dithioglycolic acid or methylarsine oxide and thiosalicylic acid. Cf. *C. A.* **25**, 1626.

Herbicide. GUSTAV LITSCHE. Fr. 694,663, April 29, 1930. A herbicide is composed of $CuSO_4$ and about 3 times the amt. of H_2SO_4 of 60° Bé.

Weed killers. CHEM. FAB. OKER & BRAUNSCHWEIG A.-G. Ger. 516,141, Dec. 5, 1928. The corrosive action on metal tanks, sprayers etc., of weed killers comprising heavy metal salts, is reduced by addn. of a nitrate, sulfate or thiosulfate of an alkali, alk. earth, or earth metal. The addn. must not give an insol. ppt. with the heavy metal salt. Thus, 1% of $NaNO_3$ may be added to a 2% soln. of $CuCl_2$.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Constitution of fusel oil obtained from fruits. G. VEGEZZI AND P. HALLER. *Mitt. Lebensm. Hyg.* **21**, 321–5(1930)(in Italian).—The constitution of fusel oil depends upon the source. An av. sample is a limpid, yellow-brown liquid, d_{15}^{4} 0.8205–0.8300, acid trace, esters 1.3% by vol. calcd. as EtOAc, furfural 0.01, aldehydes 0.3, fusel oil and EtOH 99.4. Fusel oil from fruit is the best, because its value is detd. by the AmOH content. Fusel oil from fruit contains BuOH. A considerable no. of samples analyzed contained abnormal products, such as SO_2, formaldehyde, fatty acids and amines. Fusel oil from fruit contains an appreciable amt. of compds. boiling higher than AmOH, in 1 case 13.4%. E. M. SYMMES

Production of alcohol from spent mohwra (Bassia latifolia) flowers. D. L. SAHASRABUDDHE AND V. G. PATWARDHAN. *Poona Agr. Coll. Mag.* **22**, 45–9(1930).—The spent mohwra flowers resulting from distillery operations are a nuisance in certain Indian localities. Approx. 11% of total sugar may be obtained from the carbohydrates in the spent flowers by heating the flowers with 0.05 *N* H_2SO_4 for 4 hrs. under 3 atm. pressure. By diluting the ext. from the original flowers with that from the spent flowers the addnl. sugar ferments completely, giving a proportionately higher total yield of alc. from a given wt. of flowers. Under these conditions neutralization of the H_2SO_4 before fermentation is unnecessary. K. D JACOB

The composition and determination of the barley proteins. III. Fourth report on barley proteins. The proteins of barley during development and storage and in the mature grain. L. R. BISHOP. *J. Inst. Brewing* **36**, 336–49(1930); cf. *C. A.* **24**, 1929.—Analytical data and graphical presentation are given of the proteins of varieties of English barleys, in various stages of maturation, and in mature grain before and after storage. After allowance is made for the various standard errors of the detns. it is possible to deduce that: The relationship between the quantities of the individual proteins and the total N is characteristic of the variety. Within each sep. variety, the weights of the individual proteins are simple regular functions of the total N content per thousand corns. Immature grain, if given sufficient time, reaches the natural equil. and the proportion of the various proteins will be the same as in mature grain of the same total N content per thousand corns. It is suggested that in pure grain the protein proportions may be represented in amts. per thousand corns as follows: $S = aN - bN^2$, $H = pN + qN^2$ and $G = xN$, where S = salt-sol. N, H = hordein N; G = glutelin N and N is total N per thousand corns. The values of the factors (a, b, p, q and x) are regarded as characteristic of the variety. PIETER J. F. WEBER

Institute of brewing research scheme. H. LLOYD HIND. *J. Inst. Brewing* **36**, 265–8(1930).—A report is made by the research organizer covering the autumn and winter months of 1929–1930. PETER J. F. WEBER

Preliminary note on barley proteins. The influence of the method of grinding on the estimation of barley proteins. G. HOFMAN-BANG. *J. Inst. Brewing* **36**, 381–8 (1930).—Before making estns. of different proteins in Danish barleys, the reliability of Bishop's method (cf. *C. A.* **22**, 3729; **24**, 1929) was investigated. The proteins were detd. on barleys ground to varying degrees of fineness as ascertained by shaking in a screen grader. To obtain consistent results and reach a const. value for the various proteins, the barley had to be ground in a ball mill so that 95% passed a sieve with meshes of 0.253 mm. PETER J. F. WEBER

Algerian musts of the 1930 vintage. I. G. FILAUDEAU AND A. BONIS. *Ann. fals.* **24**, 5–8(1931); cf. *C. A.* **24**, 2231.—A discussion of the results (not given in detail) found on examn. of 128 representative samples from the Department of Oran, 271 from the Department of Alger and 90 from the Department of Constantine, from which it is concluded that the quality of Algerian wines of the 1930-vintage is, on the whole, satisfactory, and even slightly better than that of the 1929 wines. **II.** POUGET, SABATIÉ AND WALLAERT. *Ibid* 8–11.—A brief discussion of the quality of the 1930 vintage in Algeria, based on the analysis of 253 samples, from which it is concluded that the constitution of the wines should be fairly well balanced, and the alc. content higher than in 1929. A. PAPINEAU-COUTURE

New apparatus for the rapid determination of the volatile acidity of wine. MARCEL MARTIN. *Ann. fals.* **24**, 36–7(1931).—The simplest method for detg. the volatile acidity of wine consists in subtracting non-volatile from total acidity; but in order to obtain consistent results it is essential that the evapn. of the volatile acids be always carried

out under strictly identical conditions. The app. described consists of an electrically heated water bath, the steam from which is passed through the sample while the latter is being heated on the bath. The construction is such that the quantity of steam passed through the sample is always the same. A. PAPINEAU-COUTURE

Dry, unpressed wine and natural wine. J. WERDER AND C. ZÄCH. *Wein u. Rebe* **11**, 272–6(1929).—Dry, unpressed wine, but not natural wine, after decolorization by animal charcoal, shows a blue luminescence in filtered ultra-violet light. B. C. A.

Rum fermentation. MARTIN FICKER AND STEFAN SZÜCS. *Zentr. Bakt. Parasitenk.*, 2 Abt., **82**, 199–211(1930).—The aroma produced during the fermentation of rum is due to the action of acetic, butyric and lactic acid bacteria. JOHN T. MYERS

Alcohol production for motors in Brazil (FREISE) **21**. Polarographic studies with dropping-mercury cathode. XVI. Electroreduction of AcH (SMOLER) **4**. The antagonostic substances formed during bacterial fermentation (KLEIN) **11C**.

Rectifying alcohol. HEINRICH PROSKE. Ger. 515,195, Dec. 21, 1928. Operative details are described. The principal features are the maintenance of an excess pressure of about 0.06 atm. in the still, and the use of a thermometer with a movable scale, which is adjusted in steam before the distn.

Acetyl methyl carbinol. T. H. VERHAVE. Brit. 337,025, June 26, 1929. A mash, such as a saccharified potato mash contg suitable N compds., a phosphate such as superphosphate and a carbonate such as $CaCO_3$, is fermented with bacteria such as *Aerobacter aerogenes* which under normal conditions produce 2,3-butylene glycol, and the mash is subjected to aeration insufficiently strong to prevent the formation of butylene glycol and the aeration is continued after the main fermentation period until at least most of the butylene glycol formed has been converted into acetyl methyl carbinol. Volatile fermentation products may be recovered by suitable washing devices, and the acetyl methyl carbinol produced may be converted into diacetyl by the action of oxidizing agents such as $FeCl_3$.

Acetic, butyric and propionic acids by fermentation. DISTILLERS CO., LTD., and H. B. HUTCHINSON. Brit. 337,153, Sept. 30, 1929. A dild. molasses soln. or other suitable sugar soln. of low concn. (various examples of which are given) is fermented with thermophilic organisms (which may be procured from animal excrement or from decompg. cellulosic material) and stronger sugar soln. is added under regulated conditions such that the concn. remains sufficiently low to prevent the formation of non-volatile fatty acids. Numerous details of procedure are described. Cf. *C. A.* **24**, 2543.

Fermentation. OLGA K. SAUER NÉE BUCHHOLZ. Ger. 513,511, Dec. 20, 1927. Yeast and bacteria prepns. are rendered stable and capable of germination by mixing to a paste or emulsion with fats at temps. not injurious to the organisms, without subsequent drying. Petrolatum, liquid petrolatum and cacao butter are mentioned as suitable fats.

Promoting fermentation reactions with activated carbon. DARCO SALES CORP. Brit. 336,207, April 2, 1929. The yield and speed of fermentation reactions (as in the production of alc., fusel oils and vinegar) are improved by adding to the fermenting mass (which may comprise a sugar or molasses soln. and suitable microörganisms) an active adsorbent agent such as activated "vegetable char" together with org. nitrogenous food substances such as a protein material. The use of "Darco" (produced from lignite) is particularly mentioned. Brit. 335,972 relates to similar processes in which the microörganisms and active charcoal are first added (preferably intimately assocd) to a soln. of medium d. of the material to be fermented and, after the d. has been reduced by the fermentation, it is increased above the initial d. by the addn. of a soln. of high d. of the material to be fermented. An example is given of the fermentation of a molasses soln. by yeast.

Fermenting sacchariferous liquids. EUGEN STICH. U. S. 1,792,450, Feb. 10. In processes such as alc. and yeast production, an app. is employed in which aeration is effected through porous diaphragms of a special degree of porosity (suitably arranged in 2 layers of material, the upper of which, in contact with the liquid, has pores of a diam. of 0.16 to 6μ while the lower layer has pores of larger diam.). Diaphragms of this particular character are stated to be suitable for producing better yields with a reduced air supply.

Pasteurizing apparatus for beer, etc. OSKAR KARY. Ger. 516,458, June 5, 1928.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Contribution of the pharmacist to the progress of chemistry and other sciences. GODOY TAVARIS. *Bol. assoc. brasil. pharm.* **11**, No. 11, 13-22(1930).—Historical review. CARLOS A. ABELEDO

Corrosive sublimate tablets. CARLOS H. LIBERALLI. *Bol. assoc. brasil. pharm.* **11**, No. 11, 31-7(1930).—The addn. of NaCl to increase the soly. of $HgCl_2$ as recommended by many pharmacopeias is not advisable. Complex formation decreases the antiseptic action which is proportional to the concn. of Hg^{++} ions. L. recommends the addn of tartaric acid which does not interfere with the dissocn. of the mercuric salt. C. A. A.

A new medicine for the treatment of piroplasmosis. L. TOBBACK. *Bull. agr. Congo Belge* **21**, 484-8(1930).—A new medicine called "Piroblue" has been recommended as a cure for cattle piroplasmosis. It is a mixt. of trypan blue and Na cholate, one of the acid constituents of bile. This medicine may be used up to concns. of 4% and in quantities from 50 to 100 cc. A complete sterilization of the blood is not obtained but this is desirable as the presence of parasites in the blood aid resistance to infection. J. R. ADAMS

Beauty creams. FRED WINTER. *Am. Perfumer* **24**, 232, 234(1929).—A review. E. J. C.

The measurement of the adsorption capacity of medicinal charcoals. HEDWIG LANGECKER. *Klin. Wochschr.* **9**, 2298-3000(1930). Animal charcoals are, in general, better adsorbents than plant charcoals. In comparing the adsorbing power of a large series of charcoals, with methylene blue, morphine and $HgCl_2$ as test adsorbates, a fairly good correlation was obtained, particularly between the last 2. Occasional discrepancies do occur, *e. g.*, a strong adsorption of methylene blue, with weak adsorption of the other 2 by the same charcoal. H. EAGLE

Components of the drug "Salpamisri." C. GRIEBEL AND G. STEINHOFF. *Arch. Pharm.* **269**, 37-49(1931).—The East Indian drug "Salpamisri" (probably derived from *Allium macleanii*) contains H_2O 9.25, ash 3.75, free acid (as malic) 1.00, fructose 2.04, polysaccharide (calcd. as fructose) 69.63, saponin (in the alc. ext. as calcd. from the difference) 3.97, Et_2O ext. 0.60, insol. 11.00%. Hydrolysis of the saponin ($C_{44}H_{80}O_{40}$) yields in addn. to sapogenin ($C_{27}H_{44}O_6$), galactose, arabinose, methylpentose and galacturonic acid. The hemolytic index is 6700, the fish index 13,300. The polysaccharide gives on hydrolysis mainly fructose and is, therefore, to be regarded as trifructosan $(C_6H_{10}O_5)_3$. W. O. EMERY

Liquor plumbi subacetatis fortis—its preparation and assay. PHILIP A. BERRY. *Chem. Eng. Mining Rev.* **22**, 421-3(1930).—Liq. plumbi subacet. fort owes its virtue to the fact that it is a highly basic Pb soln. No standards requiring a high degree of basicity have been previously suggested, neither has any method of estn. been put forward to ensure this. The following method is proposed for estg. both the Pb and Ac radicals: To a known wt. of sample add a known excess of standard $H_2C_2O_4$ soln., make up to a definite vol., filter and in an aliquot portion of the filtrate det. the excess of oxalic acid by titration with $KMnO_4$. In another aliquot portion det. total acidity by titration with 0.1 N NaOH. The difference gives AcOH. The detn. is not affected by impurities present to an extent exceeding 50% of that permitted by the B. P. To prep. the liquor triturate 320 g. powd. PbO to a smooth paste with 100 ml. distd. H_2O, transfer to a bottle, wash in the rest of the PbO with 650 ml. H_2O, shake well, add 240 g. AcOH, shake vigorously for several min. and again at intervals for 24 hrs., filter and pass through the filter water to make up to 1 l. An excess of PbO results in the sepn. of a highly basic Pb acetate from the soln., with a resultant loss of both Pb and Ac radical. The white deposit formed in making this soln. is composed of basic Pb carbonate together with basic acetate of the compn. $Pb(CH_3CO_2)_2.2PbO.4H_2O$. The d. of the official liquor is at present too definite, a range of 1.275-1.300 is suggested. The method of assay proposed is equally suited for Pb acetate. W. O. E.

History of Austrian Pharmacopeias. OTTO ZEKERT. *Pharm. Monatsh.* **12**, 2-4, 22-5(1931).—An address describing in word and picture certain of the earlier Austrian pharmacopeial documents and apothecaries. W. O. E.

Arbutin content of certain known Ericaceae. L. ZECHNER. *Pharm. Monatsh* **12**, 4-6(1931); cf. *C. A.* **24**, 685.—Some 15 ericaceous plants were exaud. with respect not only to their arbutin but also their hydroquinone content. The greatest amt. of arbutin occurs in *Arctostaphylos*. W. O. E.

Electrometric studies of complex formation. I. The citrates of bismuth. C.

MORTON. *Quart. J. Pharm. Pharmacol.* **3**, 561–74(1930).—From the results of an electrometric study in which the glass electrode was employed, it is concluded that: The view that Bi citrate is a complex "bismuthyl citric acid" is incorrect. As ordinarily prepd., the normal citrate is obtained. In the presence of alkali citrates or bicarbonates, as in the Cowley process, sparingly sol. basic complexes are formed, the compn. of the complex cation being a function of the p_H. The process of "neutralization" by alkalies consists in the reversible formation of a series of complex cations, the final product being the neutral, sol. and stable 4:1 complex, $3Bi(OH)_3.BiC_6H_5O_7$. "Bismuth and ammonium citrate" is a mixt. of this basic salt and of NH_4 citrate in the mol. proportions 1:3. The methods given in the B. P. (1914) and the Brit. Pharmaceutical Codex (1923) for the prepn. of solns. of "bismuth and ammonium citrate" are unsatisfactory, and suggestions are offered for the prepn. of non-precipitable neutral solns. of definite compn. W. O. E.

Calcium phosphate B. P. NOEL L. ALLPORT AND T. TUSTING COCKING. *Quart. J. Pharm. Pharmacol.* **3**, 578–83(1930).—Analyses of several com. samples of Ca phosphate showing the variable proportions of CaO and P_2O_5 are given. The reaction of $Ca_3(PO_4)_2$ is p_H 9.2, and that of $Ca(H_2PO_4)_2$ is p_H 4.5. Previous workers have shown that $Ca_3(PO_4)_2$ is slowly decompd. by H_2O to form $3Ca_3(PO_4)_2\,Ca(OH)_2$. Evidence is here adduced which suggests that, under certain conditions, a salt is formed with a still higher Ca content, and having the approx. compn. $2Ca_3(PO_4)_2.Ca(OH)_2$. Expts. have been made which indicate that it is impracticable to manuf $Ca_3(PO_4)_2$ by a process of pptn. in the presence of H_2O. W. O. E.

Critical observations on the directions for glass testing of the German Pharmacopeia, sixth edition. L. KROEBER. *Sprechsaal* **20**, 356(1927); *J. Soc. Glass Tech.* **13**, Abstracts 173–4; cf. *C. A.* **21**, 2047.—The German Pharmacopeia directs that medical glasses be ¾ filled with an aq. soln. contg. 1 cc. of 0.1 *N* HCl per l. and 5 drops of Me red soln. and heated for ½ hr. in a boiling water bath. After this time the red color of the soln. should not have completely disappeared. For ampoule glasses for solns. of alkaloid salts, 5 g. of the coarsely crushed glass is heated for ½ hr. in a boiling water bath with 100 cc. of water, 0.3 cc. of 0.01 *N* HCl and 1 drop of Me red soln. in a Jena glass flask previously rinsed out with boiling distd. water. After this time the red color of the soln. should not have completely disappeared. Tests for pipets, dropping glasses, wide-neck glasses and app. glass should be given. Variable results can be obtained by heating the glasses in the steam or in the boiling water, by loosely closing the necks with cotton wool or by securely sealing with cork stoppers, and by having the vessels standing or floating in the water. Preliminary cleansing of the vessels with distd. water at the ordinary temp., to remove dust and grease particles is necessary and ought to be precisely expressed. For pipets, dropping bottles and app. requiring after-working in the blowlamp an intermediate or semi hard glass is suggested. The test for ampoule glass should be more precisely defined, particularly with reference to the size of the crushed glass particles, which should be sieved to a definite uniform size and freed from dust by washing with abs. alc. The narcotine-HCl test is superior to any other durability test, because of the extreme sensitiveness of the reagent and the fact that an estn. can be made in the course of an hr. without the necessity of applying heat. G. G.

Rapid volumetric determination of nicotine by means of silicotungstic acid. B. KASANSKY. *Z. anal. Chem.* **83**, 107–14(1931).—Nicotine forms a difficultly sol. salt with silicotungstic acid of the formula $2C_{10}H_{14}N_2.2H_2O.12WO_3.SiO_2.5H_2O$ in faintly acidic solns. If, after filtering off the salt, it is decompd. with caustic alkali and the freed nicotine distd. with steam, the distillate can be titrated with acid. The ppt. can also be weighed. The modification of the method now proposed consists in first distg. off the nicotine with steam and titrating the distillate with silicotungstic acid, stopping at the point where no further clouding is produced by adding the reagent. A 12% soln. of the reagent was used in the expts. described. To carry out the detn. in a sample of tobacco, weigh out 8–20 g. of the material into a 500 cc. round-bottomed flask, add 150 cc. of water and 50 g. NaCl. Mix well to a paste and add a suspension of 5 g. MgO in a little water. Distil with steam into a 500 cc. measuring flask contg. a little concd. HCl. After distg. for 1.5–2 hrs. the distillate should show a neg. test for nicotine when tested with silicotungstic acid. Fill the flask up to the mark, mix well and transfer, with a pipet, 100 cc. into a 200–250 cc. flask. Add 2 g. of solid NH_4Cl and titrate. Standardize the reagent by means of pure nicotine soln. which has been subjected to the same treatment. The analysis of 11 samples of tobacco and nicotine exts. indicates that the method gives satisfactory results. W. T. HALL

A note on three oil-bearing grasses from Burma. D. RHIND. *Agr. J. India* **25**,

327–9(1930).—A yield of oil amounting to 0.26% of the dry matter was obtained by the steam distn. of fresh *Cymbopogon clandestinus*, a grass which grows abundantly in dry rocky open spaces on hillsides in central Burma. The oil was of a light straw-color and had a pleasant odor somewhat resembling that of ginger-grass oil. The oil tends to form an emulsion with water and a redistn. is necessary to effect complete sepn. A new species of annual *Cymbopogon*, smaller than *C. clandestinus* and differing from it in having glabrous pedicelled spikelets, yielded upon steam distn. 0.72% of the dry matter as a pale straw-colored oil, which tended to emulsify in water. Steam distn. of *C. virgatus*, an undescribed perennial species of *Cymbopogon*, yielded 0.55% of an oil having a rather unpleasant odor somewhat resembling that of Botha-grass oil. The oil had the following properties: d_{15} 0.9556, $\alpha^{100} - 28°53'$, n_{20} 1.49107, acid value 1.9, ester value 6.5, ester value after acetylation 72.8, and alc. content calcd. as $C_{10}H_{17}OH$ 21–22%. K. D. JACOB

Studies of chemical sterilization and bacteriostasis. I. Standard inhibition control for germicidal tests. JUSTINA H. HILL. *Am. J. Pub. Health* 21, 192–3(1931).—The following method of making inhibition controls is proposed by which valid germicidal tests may be made by any accepted method: Let *D* represent the no. of cc. of drug employed in the test, B the amt. of inoculum employed, *S* the amt. of the mixt. of *D* + *B* used for sub-culture and *T* the no. of cc. of broth used for sub-culture. The inhibition control then consists of the following steps: (1) Mix 1 *D* and an amt. of sterile broth equal to 1 *B*. (2) Transfer the equiv. of 1 *S* of this mixt. to 1 *T*. (3) Mix the equiv. in sterile H_2O of 1 *D* with 1 *B*. (4) Transfer the equiv. of 1 *S* of this mixt. to the 1 *T* previously used in step (2). Such inhibition controls should be made with every diln. of drug employed and with every type of organism used. It is wise to run such controls in triplicate to allow for unavoidable exptl. variation. J. A. K.

Pyrethrum. II. Culture, yield and economic future. J. CHEVALIER. *Bull. sci. pharmacol.* 37, 235–9(1930). **III. Industrial and pharmaceutical preparations. The estimation of the activity.** *Ibid* 422–31; cf. *C. A.* 24, 2804.—The pyrethrins I and II are esters of pyrethrolone, a ketonic alc., and of chrysanthemummonocarboxylic acid and chrysanthemummethyldicarboxylic acid. The flowers of pyrethrum contain at an av. 2.5–3 g. pyrethrin per kg. at a max. 5 g. Stems contain 1/6 to 1/8 as much. The industrial exts. are solns. in hydrocarbons or H_2O-sol. emulsions. The pyrethrins can be isolated as semicarbazones, but this method is not suitable for analysis. The extn. with EtOH or MeOH destroys the active substance. Chlorinated org. solvents are not satisfactory. Pyrethrin I is more efficacious than II. In the practical test on insects, different preparations show a large variation of activity. The species of the animal and the temp. have much influence. C. recommends the test on the frog. About 0.2 mg. pyrethrin injected into the lymphatic sac will kill the animal within 3 hrs. The test is unreliable at low temp. The method used for the extn. of male fern by detn. of the effect on fish showed pyrethrin active in dilutions 1:100,000. This is too sensitive for practical purposes. Com. prepns. should be tested on the class of animals they are sold for. A. E. MEYER

The culture of valerian and burdock. G. HINARD AND MLLE. PRADES. *Bull. sci pharmacol.* 37, 469–77(1930).—The compn. and growth of the plants is considered in relation to the compn. of the soils in different parts of France and Belgium. A. E. M.

Essential oil of Asarum sieboldi var. seoulensis Nakai. I. T. KAKU AND T. KONDO. *J. Pharm. Soc. Japan* 51, 8–17(1931); German abstr. 3–7.—K. and K. isolated from *Asarum sieboldi var. seoulensis* Nakai an essential oil (yield 2.21%) (I). I has the following properties: d_4^{15} 0.9988, n_D^{20} 1.5141, acid no. 1.85, sapon. no. 28.4, sapon. no. after acetylation 56.1, α_D −0.75 and MeO 21.4%. I contains palmitic acid (II), a substituted phenol (III) with mol. formula of $C_6H_3(OH)(OC_3H_5)(O_2CH_3)$. III is under further investigation. I, after removal of II and III, was fractionated under reduced pressure. The constituents isolated are: *l-pinene*, a ketone b_{10} 80–110° (*semicarbazone*, m. 185°, which, on treating with HCl, gave a free ketone, b. 200–20°, d^{19} 0.9562, n_D^{20} 1.5095, not purified further, which resembled *eucarvone*); *safrole*, which on oxidation gave piperonylic acid; and *methyleugenol*, $C_{11}H_{14}O_2$, b_{11} 127–9°, d_4^{15} 1.0443, n_D^{20} 1.5340, which on oxidation gave veratric acid, m. 180°. F. I. NAKAMURA

Common diabetic drug. IV. Constituents of the bark of Aralia chinensis L. var. grabrescens (3). S. KUWATA. *J. Pharm. Soc. Japan* 51, 17–31(1931); German abstr. 7–9; *C. A.* 24, 656.—From the alc. ext. of the bark of *Aralia chinensis L. var. grabrescens* K. isolated *α-taralin* (I) and *β-taralin* (II). I is sol. in alc., but insol. in H_2O and Et_2O; it contains a large amt. of ash (chiefly Mg, Ca and Na). It decomp. at 202–4° after electrodialysis. Analysis indicates the mol. formula of $C_{50}H_{72}O_{18}$. Hydrolysis takes

place according to the equation: $C_{50}H_{72}O_{19} + 3H_2O = C_{32}H_{46}O_4 + 2C_6H_{12}O_6 + C_6H_8O_6$. *Octaacetyl-α-taralin* decomps. 143°. Catalytic reduction of I gave glucose (decompn. 229°) which shows strong acid and Liebermann's reaction. The hemolytic action of I is similar to that of saponin of Kahlbaum and senegin of Merk. The action is weakest in a neutral soln. F. I. NAKAMURA

Digitalin of Nativelle and digitoxin. V. HASENFRATZ. *Compt. rend.* **192**, 366–8 (1931). —H. attempts to prove that the digitalin of Nativelle and the digitoxin of Schmiedeberg are the same definite chem. substances by expts. showing that these compds. have identical products of hydrolysis. The reaction of Windaus and Stein (*C. A.* **23**, 1646) representing the hydrolysis of digitoxin into digitoxose and digitoxigenin ($C_{41}H_{64}O_{13} + 3H_2O \longrightarrow C_{23}H_{34}O_4 + 3C_6H_{12}O_4$) also represents, according to H., the hydrolysis of digitalin of N. It is pointed out that digitalin of N. and digitoxin have the same toxicity (cf. Raymond-Hamet, *C. A.* **23**, 2757). ALBERT L. RAWLINS

Experimental studies on heart tonics. IV. The main factors of digitalis standardization with a new assay method. WILLIAM NYIRI AND LOUIS DUBOIS. *J. Pharmacol.* **40**, 373–401 (1930); cf. *C. A.* **24**, 5381.—Rabbits are anesthetized by intravenous injection of barbital derivatives, and the drug to be tested injected into the jugular vein. Blood pressure tracings are made (in some instances using ouabain to supplement the prepn.) until the pressure drops to zero. The prepn. tested may subsequently be used without the further complication of inaccuracy by diln. C. RIEGEL

Trypsin preparations suitable for the prevention of adhesions. ROBERT P. WALTON. *J. Pharmacol.* **40**, 403–11 (1930).—Bacteria-free enzyme prepns. could be obtained by pressure filtration of water-glycerol solns. of trypsin, and from this, by pptn. with alc. and ether, a dry sterile powder. These prepns. were found to be effective in preventing peritoneal adhesions in dogs. C. RIEGEL

Analysis of disinfectants. LESLIE HART. *Soap* **5**, 111–5 (1930).—The methods of the Food and Drug Administration St. Louis station are given for the following detns., water, alkalies, phenols, neutral oils and fatty or rosin acids, mineral oils, mineral oil in creosote oil, Liquor Cresolis Compositus, unsapond. material and fatty acids, total alkali, glycerol, sapond. cresols, water in pine oil emulsions, pine oil and fatty and rosin acids. E. SCHERUBEL

Hypophosphites. F. H. ALCOCK. *Chemist and Druggist* **113**, 613–4 (1930).—Detailed criticisms are given on the monographs of the various hypophosphites of the new Brit. Pharm. S. WALDBOTT

Glycerinum acidi borici, Brit. Pharm. J. F. BOYLE. *Pharm. J.* **125**, 453 (1930).—The present Brit. Pharm. requires a soln. of 300 g. $B(OH)_3$ in 450 g. glycerol to be evapd. to 500 g. at a max. temp. of 150°. On a large scale a higher temp. is needed for evapn., which causes darkening of the product. A simplification of the proportions instead of an increase as proposed for the new Pharm. is suggested. S. WALDBOTT

Unguentum hydrargyri compositum. J. H. RIDGWAY. *Pharm. J.* **125**, 453 (1930).—The formula ung. hydragr. Brit. Pharm. 400, cera alba, Brit. Pharm. 50, camphora 100, adeps benzoatus 450 is recommended in the place of the Brit. Pharm. formula in which the yellow beeswax imparts to the prepn. an unsightly greenish color. S. WALDBOTT

Comments and criticisms, British Pharmacopeia revision. ANON. *Pharm. J.* **125**, 453, 483, 511, 536, 561, 647–8; *Chemist and Druggist* **113**, 553–4, 587–8, 613–4, 644–5, 685–6, 746, 770–1 (1930); cf. *C. A.* **25**, 772.—More or less detailed comments were made thus far by 31 pharmacists. S. WALDBOTT

Acidum carbolicum liquefactum. Infusions. B. G. W. HOARE. *Pharm. J.* **125**, 483 (1930).—The acidum carbolicum liquefactum proposed for the new Brit. Pharm. is said to contain 50 grains in a fluid drachm. A sample made according to the new formula had a sp. gr. of 1.062; hence it contains a little below 46.5 grains per fluid drachm. Fresh infusions are superior in aroma and in efficacy in certain cases, to concd. infusions; to introduce these would be a backward step. Infusions of ergot, broom, chiretta and rhatany might be deleted. S. WALDBOTT

Syrupus ferri phosphatis compositus. F. GOLDBY. *Pharm. J.* **125**, 561 (1930).—A decoction of cudbear instead of cochineal is recommended as a permanent, bright coloring agent. Possibly a sol. powd. ext. of cudbear may be used. S. WALDBOTT

Note on linimentum camphorum. J. F. DUCKWORTH. *Pharm. J.* **125**, 647 (1930).—Peanut and ordinary cottonseed oil are not suitable for the prepn. of a satisfactory camphor liniment since the latter prepd. with these oils become solid or opaque at 0°. The *non-freezing cottonseed oil* is suitable and should be adopted in the new Brit. Pharm. S. WALDBOTT

Liquor carmini, Brit. Pharm. Codex. J. F. BOYLE AND J. H. FRANKLIN. *Pharm.*

J. **125**, 648(1930).—Evapn. of the NH_4OH soln. of carmine to near neutrality, as directed by the Codex, causes much pptn. of the coloring matter. It is suggested that after evapn. until the NH_3 is expelled, just enough soln. of NH_4OH be added to redissolve all of the pptd. carmine; or dissolve the carmine in NH_4OH and preserve the soln. with glycerol. S. WALDBOTT

A qualitative comparison of various digitalis substances. HARRY GOLD, WM. HITZIG, BEN GELFAND AND HERMAN GLASSMAN. *Am. Heart J.* **6**, 237–54(1930).—The substances used were tincture digitalis of an American-grown leaf, the same of a German grown leaf, the chloroform fraction of digitalis, tincture of adonis, ouabain and digitoxin. All have the same qual. cardiac actions, but there are extraordinary individual differences in response to the same prepn. R. C. WILLSON

Standardization of the trypanocidal activity of some aryl derivatives of arsenic acid (LAUNOY, ENGLER) **11H.** Chlorogermanites of alkaloids (TCHAKIRIAN) **6.** Explosions occurring during the use of C_2H_4 (JOHNSON, CABOT) **24.** Gases from crude oil cracked in the vapor phase [for use in preparing perfumes] (MARKOVICH, PIGULEVSKII) **22.**

CHIRIS, A.: **Contribution à l'étude des huiles essentielles.** Grasse: Antoine Chiris. 55 pp. Reviewed in *Chimie & industrie* **24**, 1507(1930).

Synthetic drugs. I. G. FARBENIND. A.-G. Brit. 337,136, Oct. 8, 1928. Acetates of 9-aminoacridine or its substitution products, which are readily water-sol. and suitable for therapeutic use, are obtained by treating the base with HOAc and isolating the product. Examples are given of the prepn. of acetates of 7-ethoxy-3,9-diaminoacridine, 9-aminoacridine, 7-methyl-9-aminoacridine and 3,9-diaminoacridine. 7-Methyl-9-aminoacridine is prepd. from *o*-chlorobenzoic acid and *p*-toluidine by a process similar to that described in Brit. 176,038.

Synthetic drugs. I. G. FARBENIND. A.-G. (Hubert Oesterlin, Karl Streitwolf and Alfred Fehrle, inventors). Ger. 517,002, Apr. 8, 1928. *o*-Phenolglycinamidearsonic acids and their substitution products are prepd. from *o*-aminophenolarsonic acids and their substitution products by the customary methods. Thus, 3-amino-4-hydroxybenzenearsonic acid may be treated with CH_2O and KCN to yield the nitrile of 4-hydroxybenzene-1-arsonic-3-aminoacetic acid, from which the acid and its amide are obtained in turn. Other examples are given also.

Therapeutic preparations. SALO BERGEL. Ger 513,694, April 24, 1929. Anti-syphilis-spirochetes prepns. are obtained by the intrapleural, intraperitoneal or intravenous injection of animals with lipoid or lipoid-albuminous substances, nucleoproteins, or albumin, inoculating them with weakened and then with fully virulent syphilis-spirochetes in the breast or abdomen and ear vein, and working up the exudations from the breast and abdomen with the ext. from the lymphatic glands, milk, ovaries, etc., and with the blood serum.

Medicinal aqueous-oil emulsions. CLAUSS B. STRAUCH. U. S. 1,791,878, Feb 10. An emulsion suitable for injection into the tissues is prepd. by dissolving a cholesterol (such as metacholesterol) and beeswax in olive oil, and adding a water-sol. drug such as insulin. Myricin may be added as a stabilizing ingredient.

Complex iron compounds of aliphatic hydroxycarboxylic acids. I. G. FARBENIND. A.-G. Brit. 335,965, June 5, 1929. Acids such as hexanetetrolic acid, gluconic acid, trihydroxyglutaric acids, glucuronic acid, saccharic and mucic acids and their isomers or salts are treated with Fe or an Fe compd. and the reaction mixt is simultaneously or subsequently neutralized with a basic substance such as alkalies or NH_3 or org bases. Water-sol. *therapeutic compds.* are obtained, and details are given of the production of Na ferrous and ferric gluconates, K-Na ferrous and ferric saccharates, quinine K ferrous saccharate and Na Fe mucate.

Anesthetics. I. G. FARBENIND. A.-G. (Max Bockmühl and Leonhard Stein, inventors). Ger. 516,285, Jan. 16, 1929. Alkamine esters of halophenyl carbonic acids are prepd. by condensing halides of halophenyl carbonic acids, or their substitution products free from N, with aliphatic amino alcs. having a tertiary N atom. Thus, *p*-chlorophenyl carbonic acid chloride (prepd. from *p*-chlorophenol and $COCl_2$) may be caused to react with $Et_2NC_2H_4OH$, yielding $ClC_6H_4OC(O)OCH_2CH_2NEt_2.HCl$, m. 132°. Other examples are given also.

Extracting organic substances. I. G. FARBENIND. A.-G. Fr. 694,602, April 28, 1930. Org. substances are extd. from animal or vegetable materials, *e. g.*, alkaloids from roasted coffee or tobacco, or sugar from beet roots, by means of liquid NH_3.

Hormones. SCHERING-KAHLBAUM A.-G. Brit. 336,470, Dec. 6, 1928. For purification of crude hormone prepns. such as those derived from animal liquids or organs, yeast or maize shoots, impurities of an ester-like character are saponified by Twitchell reagent, Dartring saponifier, lipase of castor seed, pancreas lipase or other catalytically acting agent. The saponified material may be extd. with MeOH, the ext. neutralized with alc. $Ba(OH)_2$, the filtrate concd. and then taken up in water with ether, and the hormone obtained by evapg. the ethereal soln.

Hormones. SCHERING-KAHLBAUM A.-G. Brit. 336,471, Dec. 1, 1928. Liquids contg. hormones such as urine of pregnant mammals or an aq. ext of the anterior lobe of the hypophysis are mixed with a water-sol. org. liquid such as alc. in quantity insufficient to ppt. the hormone but sufficient to ppt. impurities The hormone is subsequently pptd. as by addn. of ether, $CHCl_3$ or ethylene chlorohydrin.

Tuberculosis vaccine. CARL OTTO. Ger. 516,403, Dec 7, 1926. Pus from a dead tubercular cow is injected into a healthy cow and the latter, at the end of the incubation period, is inoculated subcutaneously with croton oil. The pus produced at the point of inoculation is removed, coagulated, and filtered. The residue is mixed with ground periosteal substance and the mixt. finally sludged with the filtered pus serum.

Alkaloids. SOC. A. S. FARMAKON. Fr. 694,055, April 16, 1930 Opium is treated with a solvent for fatty materials, preferably petroleum ether, then the soln. is agitated with acidulated water, preferably contg. HCl. The acid soln is neutralized to ppt. the alkaloids

Digitalis glucosides. WELLCOME FOUNDATION, LTD., and S. SMITH. Brit. 337,091, Aug. 8, 1929 A new glucoside is obtained by stirring the total glucosides of the leaf of *digitalis lanata* with acetone or methyl ethyl ketone, filtering, fractionally pptg. the filtrate by adding water, removing the sepd solid, adding salt to the clear liquid, drying the ppt. thus formed, and extg. it with MeOH or EtOH, on adding water to the soln. and standing, crystals of the new glucoside are obtained. Various details of purification and auxiliary treatment are given.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Purification of caustic soda obtained by the lime process. ALFONS KRAUSE AND WACLAW KLUKA. *Przemysl Chem* **15**, 6-12(1931). Caustic soda obtained by the CaO process contains Na_2CO_3, NaCl, Na_2SO_4, Na_2SiO_3 and traces of Al_2O_3 and Fe_2O_3 as impurities derived from the raw materials. Their removal by the chem. method is impossible, but it can be accomplished by concn. and cooling. Studies on the solubilities of the above salts in NaOH solns of varying concn. and at various temps. show that the concn of the NaOH should be increased up to 72 .5% at least, higher concn. not to exceed 100% being preferable. Cooling decreases the solv. of all the impurities. For the removal of Na_2SO_4 to a very low figure cooling of the NaOH to about 50° is necessary. The degree of cooling required for the removal of other impurities depends on the concn. It is well to conc. the NaOH in the presence of a definite amt. of $CaCO_3$, which forms insol. compds. with Na_2CO_3 and Na_2SO_4 and thus causes their removal from the soln. Among the impurities in the purified soda Na_2CO_3 takes first place and NaCl second. There is relatively little Na_2SO_4, and only traces of Al_2O_3 and Fe_2O_3. A. C ZACHLIN

Evaporation of electrolytic caustic soda. J. A. LEE. *Chem. Met. Eng.* **37**, 404-8 (1930).—An account is given of the continuous evapn and salt recovery system at the South Charleston plant of the Westvaco Chlorine Products, Inc The original soln. contains about 8% NaOH and 17.5% NaCl, and the final products from the steam evapn. plant are: 53 short tons of NaOH per 24 hrs. in soln. (d. 1.53) contg. also about 0.9% NaCl in soln. and none in suspension, and NaCl brine for return to the electrolytic cells. The water evapd. is about 1 million lb. per day, and the steam used, at 10 lb./sq. in. gage, about ¾ million lb. Evapn. is in 3 stages, a double effect followed by a single; then follows a continuous crystallizer and Laughlin centrifugal filter, which delivers the final caustic liquor. Swenson evaporators, Dorr thickeners and rake classifiers are employed. The materials of construction used are Ni cast Fe, Ni tubes and Monel metal. B. C. A.

Causticizing soda by Lewig's method and the use of various iron ores for this purpose. V. S. YATLOV. *J. Chem. Ind.* (Russia) **6**, 1020-7(1929).—The reaction between

soda and several Fe ores was found to be very sensitive to such factors as time, temp., subdivision of the materials, and make-up of the mix. A change in any one of them requires great readjustment in the others to bring about the same degree of reaction or the same velocity. The surface area of the reacting substances is the most important factor of all. Under the usual factory conditions the currents of hot air often carry away the finest particles of the ore, and heat sometimes produces a fusion of the reactants, with resulting diminution of the surface area. In studying the factory phase of this reaction it appears that further work should be concerned with the use of more finely subdivided ore and the use of lower temps. Special lab. analyses were worked out to obtain more accurate results than those of routine analysis. A. C. ZACHLIN

Causticizing ammonium chloride with magnesium oxide. KOJI NISHIDA AND SOEMAN NAKAMURA. *Abstracts from Rept. Central Lab. S. Manchuria Ry. Co.* 1929, 37–9.—The NH_4Cl soln. must be dild. to 2.34 *N* for perfect recovery of NH_3. This soln. uses 3 times as much fuel for distn. V. F. HARRINGTON

Dicalcium phosphate or "precipitate," and its commercial production. RUD. WEBERS. *Metallbörse* 20, 2659–60, 2755–6(1930).—A review of methods of manuf. of $CaHPO_4$ from superphosphate and bones. E. M. SYMMES

Preparation of zinc oxide by the wet method. TATSUO IRIYE. *Repts. Imp. Ind. Research Inst., Osaka, Japan* 11, No. 16, 56 pp.(1930).—The powd. Zn ore is roasted and treated with H_2SO_4. The $ZnSO_4$ thus obtained is treated with NaOH soln. under pressure. The crude Na_2ZnO_2 is freed from other metallic impurities and treated with CO_2. Pure $Zn(OH)_2$ is oxidized to ZnO by heating. F. I. NAKAMURA

Catalytic reduction of carbon monoxide under ordinary pressure. VII. Effect of alkalies on iron-copper catalysts. S. KODAMA AND K. FUJIMURA. *J. Soc. Chem. Ind., Japan* 34, Suppl. binding 14–6(1931)(in German); cf. *C. A.* 25, 1039.—With a Cu-Fe catalyst prepd. from the nitrates, 3.0 cc. of oil contg. a small quantity of a substance like vaseline was obtained at 270° from 141 l. of water gas. Addn. of 0.0005–0.05 mol. of Na_2CO_3 to the above catalyst increased its initial activity and favored formation of higher hydrocarbons. With catalysts contg. alkalies there is a high gas contraction at first, the activity diminishing gradually. The catalyst may become coated with the higher hydrocarbon. No diminution of activity occurs with alkali free catalysts. The best catalyst contains Fe 1 atom, Cu 1 atom, Na_2CO_3 0.005 mol. E. M. S.

Solid carbon dioxide from Mexico. J. W. MARTIN. *Ind. Eng. Chem.* 23, 256–8 (1931).—Oil-well gas, contg. 95% CO_2 and 5% combustible gas, issues from oil wells in the Quebrache field, Mexico, at 100°F. and a pressure of about 1000 lb. per sq. in. After purification, the gas is cooled to the liquid state and then expanded to form solid CO_2, which is shipped by rail to the Gulf Coast and by boat to New York. The plant cost is 1/4, and the transportation expense, including duty, 2/3 of the total cost. F. D. ROSSINI

Carbon dioxide in its new field of usefulness. J. C. GOOSMANN. *Ice and Refrigeration* 80, 45–9(1931).—A review of the origin, liquefaction and solidification of CO_2. Various methods now in use for the solidification of CO_2, together with the thermodynamics of each and a tabulation of the power required per ton of solid CO_2 manufd., were described previously (August, 1930). The chronology of CO_2 discovery is given, with a brief history of patent literature. Early methods of producing and compressing CO_2 snow to "dry ice" are described, and the development of the present methods of production is discussed. ALICE W. EPPERSON

Regaining iodine from phosphates. HANS JORDT. *Chem.-Ztg.* 55, 86(1931). From the analysis of the crude I_2 it is concluded that this by-product is obtained by the Dansk Svovlsyre und Superphosphatfabrik of Kopenhagen electrolytically, and the procedure is condemned as non lucrative. J. is of the opinion that by treating the gases evolved from superphosphate manuf. with CS_2, active C, H_2O_2 and O_2, the I_2 can be brought by filtration to a sufficient state of concn. to render further purification profitable economically. B. S. LEVINE

Evaporation of natural salt brines. V. P. IL'INSKII AND V. M. FILPPEO. *J. Chem. Ind.* (Russia) 6, 1163–8(1929).—The phase diagrams of Na and Mg chlorides and sulfates were studied in relation to sea water and lake brines. The processes of evapn. of natural brines with crystn. of NaCl were classified according to the types of Glauber salt, astrachanite, epsomite, hexahydrate and biphosphate. A new type of evapn. was established, based on Caspian Sea brine, accompanied by a labile system. NaCl deposits in the astrachanite sector, as a result of which NaCl deposits out in a pure state to the amt. of 30–40%. The labile equil. in the epsomite sector is disturbed by fluctuations of temp., which cause a deposition of epsomite (on the av. found for stable equil.) depending upon areas of crystn. as worked out in the lab. The amt. of

NaCl depends on the relative NaCl content of the dry residue, and to an even greater degree on the coeff. of metamorphosis. The yield of salt declines sharply with increase in the coeff. of metamorphosis. On the basis of industrial observations and data in literature concns. were established at which crystn. of NaCl begins in the various reservoirs under normal conditions and at an av. temp. of 25°. A. C. ZACHLIN

Salt and its production in history. HANNS FREYDANK. *Kali* **23**, 145–51, 161–8, 177–81(1929). E. J. C.

The utilization of bittern. I. The recovery of Glauber's salt. TORARO KATO. *Abstract from Rept. Central Lab. S. Manchuria Ry. Co.* **1929**, 40–1.—One hundred parts bittern and 40 parts NaCl are dild. with water until d. = 24° Bé. Cooling to —10° gives 45% of the Na_2SO_4 in the bittern and cooling to —19°, 70%. V. F. H.

Quinquennial review of the mineral production of India for the years 1924 to 1928. Salt. W. A. K. CHRISTIE. *Records Geol. Survey India* **64**, 276–87(1930).—About $^2/_3$ of Indian salt production is from sea water, $^1/_3$ from rock salt and the rest from areas of internal drainage. The salt works are described. **Borax.** E. H. PASCOE. *Ibid* 345–7.—Borax is not known to occur in India, although the country exports borax obtained from hot spring deposits in Kashmir and salt lakes in Tibet. **Sodium compounds (other than salt).** W. A. K. CHRISTIE. *Ibid* 432–6.—Na_2CO_3 (usually) and Na_2SO_4 deposits (occasionally) occur. Soda is evapd. from lake waters A. H. E.

The dehydrating action of coal ash. MUNENARI TANAKA. *Abstracts from Rept. Central Lab. S. Manchuria Ry. Co.* **1929**, 36–7.—Fuchun coal ash and Japanese acid clay at 260° have action only slightly inferior to $AlCl_3$ in the formation of anthraquinone derivs. from phthalic anhydride and phenols. V. F. HARRINGTON

Driers in soda factories. V. G. BAKHUROV. *J. Chem. Ind.* (Russia) **6**, 694–8 (1929).—One of the main points of weakness of the usual soda process is the low efficiency of the driers which show a heat utilization for evapn. purposes of only 45–50%. The performance of the drier can be improved by replacing by a centrifuge the continuous filter which feeds the $NaHCO_3$ into the drier, and shortening the rotary drier itself. A complete heat and material balance is calcd. for an av. plant. A. C. ZACHLIN

Performance of the Kessler apparatus. V. N. SCHULTZ, V. M. VOLCHENKO, I. V. IOSELOVSKII AND L. V. SUPONITZKII. *J. Chem. Ind.* (Russia) **6**, 928–40(1929).—A careful study was made of material and heat balance in the Kessler app. in the Degoonin H_2SO_4 chamber-process plant. The exceptionally high heat efficiency of this particular app. depends in part on the high temp. of gases entering the saturator. Utilization of heat in the Kessler app. was distributed as follows: concn. of H_2SO_4 77.9%; outgoing gases 13.2%; loss to surrounding medium 8.9%. A. C. ZACHLIN

Revivification of foam solutions for fire protection with carbon dioxide. C. B. WHITE. *Chem. & Met. Eng.* **37**, 379–80(1930).—By a few simple addns. to the fire-protection pump the soln. of $NaHCO_3$ is circulated from the bottom of the storage tank, through a small tower, and back to the upper part of the tank; it is recarbonated in the tower by gas from a cylinder. The method is preferable to adding addnl. $NaHCO_3$, because if that is done, the $Al_2(SO_4)_3$ or other acid soln. which must also be added has to be increased *pro rata*, and eventually both will have to be scrapped. B. C. A.

Potash salt recovery in cement burning (KUUSK) **20**. Apparatus for NH_3 synthesis and like catalytic gas reactions (Ger. pat. 516,249) **1**. Sulfonic acids of the fatty series (Fr. pat. 694,692) **10**. Manufacture of liquid household insecticides (Weed) **15**.

KRCZIL, FRANZ: **Untersuchung und Bewertung technischer Adsorptionsstoffe.** Leipzig: Akad. Verlag. 504 pp. M. 28; bound, M. 30.

Hydrocyanic acid. IMPERIAL CHEMICAL INDUSTRIES, LTD., T. S. WHEELER, H. A. T. MILLS, J. MCAULAY and W. B. FLETCHER. Brit. 335,947, March 27, 1929. In prepg. HCN by reaction between hydrocarbon gas and NH_3 as described in Brit. 335,585 (*C. A.* **25**, 1642), the reaction mixt. may contain one mol. proportion of NH_3 to one atomic proportion of C, or less, if the mixt. also contains H.

Hydrocyanic acid stabilization. HANS LEHRECKE (to Deutsche Gold & Silber-Scheideanstalt vorm. Roessler). U. S. 1,792,103, Feb. 10. As a stabilizing agent there is added to liquid HCN a small proportion of an ester of a halogen-substituted org. acid such as Et bromoacetate.

Nitric acid. E. I. DU PONT DE NEMOURS & Co. Brit. 336,638, April 17, 1929. Absorption in water or HNO_3 soln. of gases contg. N oxides (such as those produced by the arc process or by the catalytic oxidation of NH_3) is effected under pressures

of 50–150 lb. per sq. in. in a specially constructed tower (details of which are described) comprising 10 to 20 sections for gas and liquid contact. The gases are alternately scrubbed with liquid in each section and further oxidized on their passage to the next higher section. Cf. *C. A.* **24**, 2840.

Nitric acid production by catalytic oxidation of ammonia. E. I. DU PONT DE NEMOURS & Co. Brit. 336,233, March 27, 1929. In a process involving oxidation of NH_3 to nitric oxide, further oxidation of the nitric oxide to NO_2, and absorption in water condensed from the oxidized mixt., the oxidation and absorption are effected under pressure (suitably 4–10 atm. or higher), and the oxidized mixt. is cooled quickly to effect sepn. of water before oxidation of the nitric oxide takes place. An arrangement of app. and various details of procedure are described.

Recovery of nitric acid. MAHLON G. MILLIKEN (to the Hercules Powder Co.). Can. 308,879, Feb. 24, 1931. Waste gases from nitrating operations are treated for the recovery of HNO_3 by mechanically removing H_2SO_4 mist, introducing NH_3, and sepg. out substantially pure NH_4NO_3 formed by combination of the NH_3 with HNO_3 vapor of the waste gases

Sulfuric acid. HENRI N. M CORBILLÉ. Fr. 694,080, April 17, 1930. The residual gases from the Pb chambers are practically perfectly denitrated, and the loss in S is suppressed by submitting the gases to the action of H_2SO_4 only after they have reached a degree of oxidation corresponding to the presence of NO and NO_2 in equimol. proportions, the treatment with H_2SO_4 being then reduced to about 5–10 sec. The gases are given a final washing with alkali carbonate or bicarbonate.

Sulfuric acid. I. G. FARBENIND. A.-G. Fr. 695,098, May 5, 1930. Constituents of HNO_3 are eliminated from impure H_2SO_4 contg. more than 60% of H_2SO_4 by adding SO_2 dissolved in an appropriate solvent to the H_2SO_4 to be purified and treating the mixt. with a current of gas at a high temp.

Cooler for sulfuric acid. A.-G GEORG EGESTORFF'S SALZWERKE UND CHEM. FAB. Ger. 516,366, July 22, 1928.

Residue of sulfonic acids from oil refining. STANISLAW PILAT and JAROSLAW SEREDA. Fr. 694,236, Apr. 19, 1930. The residue of sulfonic acids obtained in the refining of oils with H_2SO_4 is neutralized with alk. earth hydroxides and treated with an alkali carbonate to obtain alkali sulfonates, which may be treated with mineral acids to obtain the free acids. The products are used as *wetting*, *emulsifying* and *fat splitting* agents.

Oxidation of ammonia. I. G. FARBENIND. A.-G. Fr. 694,790, May 1, 1930 NH_3 is oxidized with catalysts of the Pt group, covered with Rh alone or with a mixt of Rh with other metals of the Pt group. The Rh is heated to redness to make it adhere better before use as a catalyst

Apparatus for the catalytic oxidation of ammonia. SOC. ANON. D'OUGRÉE MARIHAYE. Ger. 516,444, April 17, 1928.

Mono- or di-alkali cyanamides. JEAN MARGOLES. Fr 694,093, April 17, 1930 $CaCN_2$ is caused to react with an alkali phosphate in dil or concd. soln. and at any temp.

Alkali phosphates. METALLGES. A.-G Fr. 694,667, April 29, 1930. Alkali phosphates, particularly Na_3PO_4, are prepd. by heating NaCl or other alkali chloride in a cyclic operation with FeS in the presence of O and steam, the Na_2SO_4 formed is heated with Fe-P to obtain Na_3PO_4 and FeS which is used again.

Alkali phosphates. METALLGES. A.-G. (Freiherr Conway von Girsewald, Hans Weidmann and Gerhard Roesner, inventors). Ger. 516,382, June 1, 1929 See Brit. 335,492 (*C. A.* **25**, 1643).

Pyrophosphates. METALLGES. A.-G. Fr. 693,913, April 15, 1930 Acid di-Na pyrophosphate ($Na_2H_2P_2O_7$) is made by evapg. under vacuum solns. of phosphoric acid contg. the corresponding amt of NaCl. Temps. which would cause the formation of insol metaphosphates are avoided.

Phosphorus compounds. VICTOR CHEMICAL WORKS. Fr. 694,278, April 22, 1930. An app. is described for the manuf. of P compds., consisting of a combustion chamber and means for leading in gases contg. P.

Anhydrous chlorides. I. G. FARBENIND. A.-G. (Max Jaeger, Robert Suchy and Wilhelm Moschel, inventors). Ger. 513,529, May 30, 1926. Addn. to 502,646. Anhyd. chlorides of Li, Ca, Zn and Ce are obtained by the method used in 502,646 (*C. A.* **25**, 564) for anhyd. $MgCl_2$, *i. e.*, by heating a mixt. of metal chlorides and oxides of Li, Ca, Zn or Ce. In one example, a mixt. of $CaCl_2$ and CaO are heated electrically in a current of Cl_2 and CO or HCl. In another, NaCl and KCl are heated with CeO_2.

Alumina. MAX BUCHNER. U. S. 1,792,410, Feb. 10. Aluminiferous material such as clay is treated with HNO_3 insufficient to combine with all the alumina in the material, and the Al nitrate soln. is sepd. and decompd. by heat. Cf. *C. A.* **24**, 5947.

Alumina. WM. GUERTLER. Ger. 516,278, June 11, 1929. In the manuf. of Al_2O_3 by heating Al silicates with $CaCl_2$ or like chloride at 650–1000°, the HCl evolved is caused to act again on the reaction mixt. when the latter has cooled to below 400°. Ca silicate is thus decompd. and $CaCl_2$ is recovered. The reaction product is worked up by extg. $CaCl_2$ with water, and extg. $Al(OH)_3$ from the residue with HCl, the $AlCl_3$ soln. being then worked up in known manner. Details are given.

Ammonium carbamate. I. G. FARBENIND. A.-G. Brit. 336,206, July 1, 1929. Reaction under pressure is effected with excess of liquid or gaseous NH_3 and NH_4HCO_3, $(NH_4)_2CO_3$ or bicarbonates of alkali metals or of Mg (in which latter cases carbonates of the alkali metals or Mg are also formed). Mixts. of salts produced may be sepd. by treatment with water, aq. or liquid NH_3, MeOH, etc., and the reactions may be carried out in the presence of water.

Diammonium phosphate. I. G. FARBENIND. A.-G. Brit. 336,008, July 10, 1929. Di-NH_4 phosphate soln. is mixed with the dry salt to obtain a moist product which can be dried at a temp. of about 60–80° without loss of NH_3. The soln. used is preferably made from H_3PO_4 still contg. some of the H_2SO_4 used to decompose the crude phosphates, evapd. to a sp. gr. of 1.4–1.5 and cooled. The contained Ca is thus pptd. as sulfate and is removed, the soln. being then neutralized. The pptd. Fe and Al may be left in the soln.

Calcium carbonate. LOUIS PERIN. Fr. 694,507, Aug. 1, 1929. Chemically pure $CaCO_3$ is obtained by converting the natural carbonate into chloride and treating the chloride with $(NH_4)_2CO_3$ which ppts. pure $CaCO_3$. The $(NH_4)_2CO_3$ is recovered by treating the residual soln. with CaO and carbonating with CO_2, the $CaCl_2$ being then treated as indicated.

Dicalcium phosphate and potassium nitrate. A. HOLZ and T. VAN D. BERDELL. Brit. 336,692, July 30, 1929. Material contg. tri-Ca phosphate is treated with a mixt. of H_2SO_4 and HNO_3 (preferably in the ratio of 1 to 4 mols.), $CaSO_4$ is removed from the soln. of H_3PO_4 and $Ca(NO_3)_2$ formed, and the latter is then treated with KOH or K_2CO_3. Di-K phosphate formed is immediately converted into di-Ca phosphate, and the latter is removed and dried; the remaining KNO_3 soln. may be evapd. to dryness, the salt may be mixed with di-Ca phosphate contg. some $CaSO_4$, and the latter may be converted into $(NH_4)_2SO_4$. Cf. *C. A.* **25**, 1324.

Carbon monoxide. HENRY DREYFUS. Fr. 694,223, April 19, 1930. Mixts. of CO_2 and H, particularly those resulting from the washing waters of industrial mixts. of these gases, are passed over chromite heated to 800–900°, and the resulting gases are passed over hot C (coke, coal, wood, etc.) in any manner used for making CO from CO_2.

Carbon dioxide. I. G. FARBENIND. A.-G. Fr. 694,871, May 2, 1930. Liquid CO_2 is prepd. by the catalytic dissocn. under pressure of CO or gases contg. it, and condensing under pressure the CO_2 formed. Examples are given using Ni as a catalyst.

Solid carbon dioxide. KARL FEHRMANN. Ger. 513,514, Nov. 4, 1928. A method and app. are described for regulating the evapn. of solid CO_2 by using the gas pressure developed.

Solid carbon dioxide. GES. FÜR LINDE'S EISMASCHINEN A.-G. Ger. 513,528, Apr. 17, 1929. Addn. to 463,125. Solid CO_2 is obtained by sepn. of its vapor from a solidified mixt. and resolidification. App. is described.

Chromium oxide. I. G. FARBENIND. A.-G. Brit. 336,671, July 19, 1929. A *product suitable for use as a pigment, polishing agent* or *for metallurgical purposes* is obtained by igniting (suitably at about 900°) Cr hydroxide obtained by reducing an alkali chromate or dichromate (free from coloring impurities such as Fe) with S in soln. or partial soln. and suspension. Alkalies and polysulfides, etc., may be used as initial materials for the reduction, and the color of the ignited product varies from yellow to blue as the temp. of reduction is increased (reduction temps. of 105–120° being suitable). $Na_2S_2O_3$ may be crystd. from the spent liquor and the latter then reused, or part of the S may be recovered by treatment of the liquor with H_2SO_4.

Phosphorus oxychloride. J. S. DUNN, F. BRIERS and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 336,065, Sept. 6, 1929. Ca phosphates such as rock phosphate or double superphosphate are reacted on by phosgene under such conditions as constantly to expose fresh surfaces to the reacting gases (as by agitation with admixed pebbles in a rotary kiln), and the $CaCl_2$ (formed from $CaCO_3$ in the raw material) is prevented from forming a protective covering. The mass may be washed with water at inter-

vals and reused after drying, and inert solids such as coke or washed residues from a previous operation may be added. Alternatively, the phosphate may be mixed with C activated by treatment with Cl at 1000°, and Cl alone or mixed with CO may be used instead of phosgene. The temp. may be raised during the reaction from about 350° to 600° (or higher if Cl alone is used).

Phosphorus oxychloride. J. S. DUNN, F. BRIERS and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 337,123, Sept. 6, 1929. $POCl_3$ is produced by reaction of $COCl_2$, or its equivs. such as CO and Cl, upon natural Ca phosphate such as phosphate rock, which has been subjected to a preliminary treatment to remove other reactive Ca compds. such as $CaCO_3$ (suitably by conversion of the latter into sol. compds. and washing out these). In a modified procedure, Cl may be passed over a mixt. of the phosphate with active C. Various details of treatment are described.

Sodium sulfide. I. G. FARBENIND. A.-G. Brit. 336,251, June 10, 1929. Anhyd. Na sulfide is made by reducing Na_2SO_4 in the mass with H or other suitable gaseous reducing agent at such a temp. (suitably 500–600°) that the mass is maintained in the solid state throughout the reaction. The reaction may be accelerated by the addn. of a small proportion of Na sulfide or the crude melt obtained in its manuf., NaOH, S, Fe or Ni or mixts. or compds. of these. Cf. *C. A.* **24**, 2253.

Zinc hydrosulfite. HANS PICK. Austrian 120,389, July 15, 1930 In the manuf. of ZnS_2O_4 by treating Zn suspended in EtOH with SO_2, better yields are obtained by effecting the reaction in the presence of a small quantity of a metal less electropos. than Zn, *e. g.*, Sn or Ag. The addnl. metal may be pptd. in the presence of the Zn, or an inert carrier on which the metal has been pptd. may be used. An example is given.

Zinc oxide. COMPAGNIE FRANÇAISE DE TRANSFORMATION MÉTALLURGIQUE. (René H. L. Aubert, inventor). Fr. 693,947, Apr. 15, 1930. In the manuf. of ZnO the greater part of the heat necessary for the distn. of the metal is obtained from the radiant heat of the combustion flame of the Zn vapors. A suitable app. is described.

Enriching natural phosphates. AKTIEBOLAGET KEMISKA PATENTER. Fr 694,946, May 3, 1930. Natural phosphates are enriched by heating them with H_3PO_4 so as to form tribasic phosphates of alk. earth metals.

Reactivating carbon, silica gel, etc. JOSEF MUCHKA. Austrian 120,098 and 120,101, June 15, 1930. The materials are entrained in a current of a reactivating liquid or gas, in a manner analogous to that employed in cleaning filter sand. App. is shown (120,098). Austrian 120,101 describes modified app. for the same purpose

Hydrogen and carbon monoxide from methane, etc. I. G. FARBENIND. A.-G Brit. 336,635, April 8, 1929. Gaseous hydrocarbons such as CH_4 or gas mixts. contg. it (other than coke-oven gases or other gases contg. liquid hydrocarbons) are passed, with water vapor (and if desired with further addn. of air or O), through a water-gas producer in which coke or other carbonaceous fuel is undergoing gasification which is carried out without addn. of CO_2 (the coke having a temp. of at least 800–1000°). As starting material there may be used a natural gas or waste gases from NH_3 synthesis, hydrogenation of coal, cracking, etc. Various details and modifications of procedure are described. Cf. *C. A.* **25**, 783.

Hydrogen and carbon monoxide from methane, etc. I. G. FARBENIND. A.-G. Brit. 336,944, April 8, 1929. Various details are described of a process generally similar to that of Brit. 336,635 (preceding abstract).

Hydrogen and oxyacids of phosphorus. I. G. FARBENIND. A.-G. Brit. 337,109, Aug. 24, 1929. P or P acids of lower stage of oxidation than H_3PO_4 are heated under pressure with anhyd. H_3PO_4; *e. g.*, yellow P 10 parts is heated for 3 hrs. with H_3PO_4 85 parts at 300° under 83 atm. pressure, by which an acid contg. 80% P_2O_5 is obtained.

Metallic sodium and potassium. JOSÉ YLLA-CONTE. Fr. 694,587, April 26, 1930. An app. is described for the production of K and Na by reduction of the carbonate or hydroxide with C under reduced pressure produced by pumps drawing off the gases formed. Cooling means is placed between the reaction chamber and the pumps.

Catalysts. I. G. FARBENIND. A.-G. Fr. 694,076, April 17, 1930. Very active catalysts are prepd. by disseminating catalytic substances in an extremely fine state of division, preferably in the atomic state, in particularly refractive stabilizers not modified under the conditions of the process and bringing the substance into the state of catalytic activity without using high temps. If oxides or salts are used, they are reduced with active H in the stabilizer.

Polymerization products. I. G. FARBENIND. A.-G. Fr. 693,920, April 15, 1930. Polymerization products of good mech. properties are made by heating diolefins, such

as butadiene, while adding alkali metals or their alloys or org. compds. of alkali metals in portions during the polymerization.

Urea-formaldehyde condensation products. I. G. FARBENIND. A.-G. (Johannes Kuchenbuch and Karl Eisenmann, inventors). Ger. 516,995, Apr. 13, 1929. Addn. to 490,012 (*C. A.* **24**, 2256) and 495,790 (*C. A.* **24**, 3615). Products of reduced inflammability are obtained by effecting the processes of the prior patents in the presence of halogenated aromatic alcs. or of di- or polyhydric alcs. partly etherified or esterified with one or more halogenated aromatic radicals. Suitable condensation media are *o*-chlorobenzyl alc., glycol monobromophenyl ether and glycol bromosalicylate. Examples are given.

Plastic masses. DEUTSCHE HYDRIERWERKE A.-G. Ger. 513,771, Jan. 24, 1926. A softening and gelatinizing agent for such plastic masses as cellulose esters, lac, etc., consists of esters of hydroaromatic carboxylic acids which have a wholly or partly hydrated nucleus. These may be combined with other softening agents. Preferably, the agent is an ester of dicarboxylic acids obtained by the oxidation of partly hydrated naphthalene with a wholly hydrated ring, or of hydronaphthols.

Artificial materials. I. G. FARBENIND. A.-G. Fr. 694,944, May 3, 1930. Artificial materials are made of fibrous materials agglutinated with condensation products of dicarboxylic acids of ethers or thioethers and polyhydric alcs. or their solns. The product is submitted to a hardening under pressure. Examples are given of the use of the condensation products of diglucolic acid with glycerol in acetone; thiodihydracrylic acid with glycerol in a mixt. of dioxane and acetone, etc.

Composite articles of materials such as rubber and bakelite. B. O. WARWICK and M. WARWICK (trading as Warwick's Time Stamp Co.). Brit. 336,292, July 12, 1929. Materials such as uncured rubber and bakelite powder are united by molding together under heat and pressure to form a hardened mass.

Pectins and mucilages. HENRI OLIVIER. Fr. 694,460, July 27, 1929. Pectins and mucilages contained in plantain seeds are extd. with water in a closed vessel at a temp. above 100°.

Casein. CHARLES C. T. PORCHER and JEANNE BRIGANDO. Fr. 694,032, April 16, 1930. Casein contg. little ash is prepd. by pptn. with lactic acid, AcOH, HCOOH, HCl or H_2SO_4 at the isoelectric pt. of a p_H value of 4.7. The casein is afterward heated in its serum to 60–65°, the serum decanted and the casein washed in acidulated water. Paracasein and Ca paracaseinate are prepd. from com. lactic casein.

Dialyzing membrane. FILTRES PHILIPPE. Fr. 695,007, Aug. 2, 1929. A membrane for dialyzing org. products in the presence of solvents is made by dipping a support, *e. g.*, of cloth into a bath of rubber and drying. Fr. 695,008 describes the application of the membranes for the *purification of mineral oils.*

Porous material for heat insulation, filters, etc. I. G. FARBENIND. A.-G. Brit. 336,318, July 19, 1929. Siliceous material, such as that obtained in the manuf. of alumina by treating burnt clay with HCl, is heated with alkali such as a 20% NaOH soln. and then further heated (suitably to 300–500°) to effect swelling and production of a porous product suitable for heat, sound or elec. insulation, filters, diaphragms, absorbents, fillers of rubber, lacquer, paper, etc. Numerous examples of siliceous materials and alk. reagents which may be used are given. MgO and $MgCl_2$ may be employed to strengthen the product, and org. fillers may be burnt out to increase the porosity of the product if desired.

Bearing material. CHARLES F. NOFTZGER. U. S. 1,791,834, Feb. 10. Bearings are formed of ground sericite schist and an insol. condensation product of a phenolic compd. and CH_2O.

Use of diethyl phthalate as a cooling fluid in heat-exchange systems such as engine-cooling systems. DAN J. KILLEN (to Waldemar C. Wehe). U. S. 1,791,818, Feb. 10. Diethyl phthalate is used alone undild.

Apparatus for calcining seaweed. J. C. MORRISON. Brit. 336,500, Dec. 16, 1929. Structural features.

By-product whiting. JOHN W. CHURCH and HARVEY G. ELLEDGE (to The Pure Calcium Products Co.). Can. 309,082, Mar. 3, 1931. Whiting is produced by the reaction of $Ca(OH)_2$ and Na_2CO_3, sepn. of the major portion of the NaOH formed, formation of a slurry of the impure $CaCO_3$, treatment of the slurry with CO_2 to convert the remaining NaOH into a carbonate, further treatment of the slurry with $CaCl_2$ to form NaCl and the washing out of the NaCl.

Applying hood caps to bottles. CARLETON ELLIS (to Ellis-Foster Co.). U. S. 1,792,006, Feb. 10. Binder-carrying caps such as those of heavy paper treated with a mixt. of carnauba wax 80, rosin 18 and S 2% are applied to a container such as a

bottle while maintaining the temp. sufficiently high to render the binder of the cap plastic, but low enough not to cause undesirable adhesion between the cap and container.

Use of aqueous oil emulsions to take up shocks in shock-absorbing devices. NOEL B. NEWTON. U. S. 1,791,832, Feb. 10. Emulsions may be used such as those prepd. from water 10 gals., lard oil 2½ gal., Na_2CO_3 7 lb. and soft soap 2 lb. or from olein 3–5, MeOH 1, mineral oil of 0.885 sp. gr. 19, glycerol 1, KOH 1 and water 75 parts.

Treated receptacle for preventing tarnishing of silverware. GEORGE E. HERRING. U. S. 1,791,594, Feb. 10. Tarnishing is inhibited by treating the inner surfaces of a silverware case with a substance such as Pb acetate which arrests the tarnishing action of H_2S and SO_2.

Wetting, etc., agents. DEUTSCHE HYDRIERWERKE A.-G. Fr. 694,250, April 22, 1930. Piperidine and its homologs, either alone or with org. acids are used as washing, cleaning, wetting or emulsifying agents. Cf. *C. A.* **25**, 1048.

"Lime-nitrogen." ELEKTROCHEMISCHE GES. and H. GROHMANN. Brit. 336,677, July 20, 1929. Ca carbide is heated in N which is supplied through channels uniformly throughout the mass (as through cardboard tubes in the mass). The mass is heated to 800° or higher, and it fuses but remains sufficiently viscous that the channels are not closed.

Apparatus for making lime-nitrogen. GUSTAV HILGER. Ger. 516,445, Sept. 20, 1929.

Device for blowing combustion air into shaft kilns for lime, etc. MASCHINENBAU-ANSTALT HUMBOLDT. Ger. 516,087, Feb. 22, 1929.

Rotating furnace for dehydrating gypsum. ÉTABLISSEMENTS POLIET ET CHAUSSON Fr. 695,029, Aug. 6, 1929.

Protecting leather, wallpaper, wood and other materials from fungi. I. G. FARBENIND. A.-G. Brit. 336,244, May 1, 1929. The materials (including textile materials other than those of wool) are protected against mildew or other fungi by treatment with a hydroxydiarylmethane or hydroxytriarylmethane contg. one or more univalent halogen phenol residues, *e. g.*, ox hide is treated with a caustic alkali soln. of the condensation product from formaldehyde and 2 mol. proportions of *p*-chlorophenol (dil. H_2SO_4 being added to neutralize the alkali). Various other examples are given.

Pencil compositions. EAGLE PENCIL CO. Ger. 516,229, July 16, 1929. Addn. to 505,144 (*C. A.* **24**, 5951). The compn. described in Ger. 505,144 is modified by using other sulfonated oils, *e. g.*, sulfonated olive oil, in place of Turkey-red oil.

Stencil sheet. SHINJIRO HORII. U. S. 1,792,095, Feb. 10. Sheet material such as Japanese yoshino paper is coated with a compn. comprising a mixt. of esters of polysaccharides such as cellulose acetate, cellulose nitrate, starch acetate, starch palmitate or mannan acetate with naphthenic acid glycerides and a heavy hydrocarbon oil. Cf. *C. A.* **25**, 1646.

Materials for electrodynamic microphones. CLINTON R. HANNA (to Westinghouse Elec. & Mfg. Co.). U. S. 1,792,300, Feb. 10. A conical diaphragm has a coil support at its smaller end formed of material such as celluloid to which a coil is united by a cementing material such as a cellulose acetate compn. which when applied contains an ingredient having a solvent action on the material of the support.

Photographic sound records. F. K. CROWTHER and BRITISH TALKING PICTURES, LTD. Brit. 336,559, July 4, 1929. Various mech. details of manuf. are described.

Dental amalgams. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORMALS ROESSLER (Fritz Ungerer, inventor). Ger. 513,957, May 9, 1928. The amalgams are formed by shaking the constituents in a closed vessel in the presence of a small quantity of dil. NaOH.

Apparatus suitable for heating thermoplastic dental materials, etc. DANIEL S. LOCKWOOD. U. S. 1,792,434, Feb. 10. Structural features.

Dental cement. JORGEN E. THOMSEN. U. S. 1,792,200, Feb. 10. A dry powder suitable for use as a dental cement on addn. of water alone consists of approx. 145 parts by wt. of a silicate cement and 40–60 parts by wt. of pure H_3PO_4 or its equiv. in the P_2O_5 radical, the ingredients being mixed together at a temp. sufficiently low (suitably at room temp.) to retain the mixt. in an unstable condition capable of reacting with the added water to form a plastic mass capable of hardening.

"Frost-preventive" or thawing agents for use on railway switches, etc. G. ERDBRÜGGER. Brit. 336,739, Sept. 9, 1929. Ground raw carnallite is used in mixture with liquid bitumen or crude mineral oil.

"Artificial ice" skating rinks. H. REESER. Brit. 336,218, June 4, 1929. A suitable foundation is covered with a layer which may be formed from Na hyposulfite 70

and borax 30 parts with a small quantity of alum, and the surface may be covered with a soap and stearin compn.

Mixed felt for use as a box toe material. HENRY P. SHOPNECK (to Arden Box Toe Co.). U. S. 1,791,537-8, Feb. 10. A short-fibered material such as wood pulp 60, is used with leather fibers or wool and cotton fibers 30 and asbestos fibers 10%, felted and impregnated with a thermoplastic material. Cf. *C. A.* **24**, 1478.

Filter for use in tobacco pipes. Z. BRAZAY. Brit. 337,200, Dec. 5, 1928. Filter wads are formed of material such as cotton or filter paper which has been treated with dil. H_2SO_4, heated sufficiently to carbonize the fibers on their outer surface, and then impregnated with $FeCl_3$ or other material such as citric, tartaric or tannic acid adapted to fix the nicotine. The H_2SO_4 still present after the carbonization is neutralized with NH_3.

Apparatus for supplying fire-extinguishing foam to oil tanks, etc. MINIMAX A.-G. and PYRENE CO., LTD. Brit. 337,221, Nov. 14, 1929. Structural features.

Co nposition for fireproofing fibrous materials. S. A. I. G. (SOC. ANON. INVENZIONI GUADAGNIN). Brit. 336,863, Dec. 10, 1929. Articles are immersed or treated under pressure with a soln. formed of NH_4Cl or $(NH_4)_2CO_3$ 12, H_3BO_3 8, NH_3 8 and water 70 parts.

Fire-extinguishing compositions. MINIMAX A.-G. Ger. 516,426, July 28, 1927. Compns. comprising CCl_4 and NH_3 (or a compd. thereof) are rendered stable to storage by means of a phys. or chem. drying agent, which may be added to the compn. or located in the container therefor. Suitable drying agents are soda-lime, anhyd. Na_2SO_4, P_2O_5, and silica gel. Cf. *C. A.* **25**, 1348.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Quinquennial review of the mineral production of India for the years 1924 to 1928. Glass-making materials. G. V. HOBSON. *Records Geol. Survey India* **64**, 392–9 (1930).—Chem. analyses of Indian glass sands are given (SiO_2 96.00, 98.95, 99.39, 98.10 and 99.80). ALDEN H. EMERY

Dependence of the properties of glass on its thermal history. E. BERGER. *J. Soc. Glass Tech.* **14**, 280–94(1930). The properties of glass depend upon the state of aggregation within the mass. Annealing produces an inner state of equil. and hence a change in double refraction, density, etc. H. F. KRIEGE

The decomposition of refractory silicates by fused ammonium fluoride and its application to the determination of silica in glass sands. A. C. SNEAD AND G. FREDERICK SMITH. *J. Am. Chem. Soc.* **53**, 483-6(1931). The use of an NH_4F fusion for decompn. of glass sands is rapid and quite satisfactory for routine analyses. M. A. EDDY

Manufacture of photographic lenses. ROBERT S. GUILFORD. *Glass Ind.* **12**, 23–7 (1931).—The methods employed at the Hawkeye Works of the Eastman Kodak Company are described. H. F. KRIEGE

Destruction of glass by superheated steam. F. H. ZSCHACKE. *Chem.-Ztg.* **55**, 41 (1931); cf. *C. A.* **24**, 4130.—No glasses are completely immune to the attack of water vapor, but a typical compn. and list of sources are given for glass which is satisfactorily resistant. T. H. CHILTON

Term "pounds of glass per pound of coal" is misleading. JOHN W. ROMIG. *Glass Ind.* **12**, 28 9(1931).—The factors requiring consideration in a discussion of melting efficiency are furnace construction, regenerative capacity, temp. in the tank, quality of fuel and pull on the tank. H. F. KRIEGE

A little-known action of animal glue and other adhesives on glass. GUSTAV GÜNTHER. *Chem.-Ztg.* **55**, 37-8(1931).—A sign was affixed to a store window with dextrin and the glass underneath was "ruined," and damages were sought. It was demonstrated that any adhesive might, when removed after drying, cause an irregular frosting effect, if the glass was old and had been frequently polished. A flexible paste is recommended for such cases. T. H. CHILTON

Notes on clay and burned clay products. G. S. STAIRS. *Eng. J.* **13**, 688–93 (1930).—Some of the properties of clay as a material and the methods of manuf. of such clays which are of importance to structural engineers are indicated. The manuf. of brick and the manuf. of structural tile are outlined. Advantages and disadvantages

of the car *tunnel* and the down-draft *kilns* are listed. A flowsheet of mfg. processes in the clay product industry and a brief discussion are included. W. H. BOYNTON

Behavior of soluble salts during the burning of clays—the problem of efflorescence. IV. Conditions for the formation of sulfate efflorescences in ceramic materials. A. SIMON AND K. SCHMIDER. *Z. angew. Chem.* **43**, 380–2(1930); cf. *C. A.* **24**, 1949.—Clay material contg. quartz, or quartz material was admixed with varying quantities of lime (contg. MgO) and heated at 1000° for 3 hrs. and then maintained at this temp. for 5 hrs. in air contg. 0.5 or 2% SO_2. For the same lime content the amt. of sulfate formed rises with increasing SO_2 concn., the amt. of SO_2 absorbed being directly proportional to its concn. Similarly, for the same SO_2 concn. the quantity of this gas absorbed and of sulfate formed increases with the rise in lime content, but at a much lower rate than the latter. The temp. interval 300–600° is most favorable for the absorption of SO_2, max. absorption probably occurring between 400° and 500°. In the firing of ceramic materials, therefore, the interval 300–600° should be passed as quickly as possible in order to avoid absorption of the SO_2 produced by the combustion of the S of the coal. No absorption occurs at 750° and above, the sulfate detected in the expts. carried out at 1000° is formed during the heating up to this temp., and although the dissocn. pressure of $CaSO_4$ in the presence of SiO_2 is already exceeded at 750°, greater energies than are present are necessary before decompn. occurs. The drying and preheating of ceramic material, therefore, should be completed as far as possible in the absence of SO_2, while for sharp firing, coal contg. S may be used without adverse effect. B. C. A.

Technical analysis of clays with the aid of the microscope. H. MÖHL. *Sprechsaal* **62**, 731–4(1929).—The methods employed are described, together with the microscopical characteristics of various clays B. C. A.

Manufacture of light-weight units of clay and combustible admixtures. AUG. E. BUCH. *Ziegelwelt* **62**, 31–2(1931).—A fat clay is essential as binder while a variety of admixtures such as sawdust may be used. H. F. K.

Effect of temperature on the cracking of plastic clay; with some notes on Temperature gradients inside the clay during steady heating in a saturated atmosphere and on drying at 100°. S. R. HIND AND F. WHEELER. *Trans. Ceram. Soc.* (Eng.) **29**, 314–25 (1930); cf. *C. A.* **24**, 5955.—It was shown that clay cracks vigorously when heated in a satd. atm. Hence the failure during drying cannot be due to unequal contractions of different parts of the ware nor to the bursting force developed by entrapped water vapor. A definite relationship exists between the crit. temp. and the water content of the clay in a satd. atm. The actual range over which cracking occurs is a property of the clay. With 4" cubes of clay heated at a regular rate the thermal diffusivity increases as the water decreases from 30.7 to 17.4%, after which it decreases. Clay must be air-dried to a certain water content beyond which the drying process may take place at higher temps. without serious results. H. F. K.

Influence of atmosphere on the load-bearing capacities of fire bricks. H. T. S. SWALLOW. *Trans. Ceram. Soc.* (Eng.) **29**, 339–53(1930).—By use of the Mellor and Moore load-test furnace as modified by Dale, several types of bricks were tested in oxidizing, reducing and steam atms. It is suggested that the influence of a reducing atm. at high temps. is apparent more in an increase in the amt. of contraction than in a reduction in refractoriness or load-bearing capacity. At the temps of these tests (1200–1280°) the action of steam appeared to be negligible as a reducing atm. The Fe content of the brick must be considered when tests are made under oxidizing conditions. It is suggested that the term "oxidizing atmosphere" be defined as that in which FeO cannot exist in stable equil. but is raised to at least Fe_3O_4. H. F. K.

Effect of repeated burning on the structure and properties of lime-bonded silica bricks. II. Determination of the proportions of quartz, cristobalite and tridymite. W. HUGILL AND W. J. REES. *Trans. Ceram. Soc.* (Eng.) **29**, 381–4(1930); cf. *C. A.* **23**, 5289.—Using the optical method of reading the linear intercepts for each constituent in 2 directions at right angles, H. and R. detd. the amts. of the 3 forms of SiO_2 and of glass present after repeated burnings. The amt. of unchanged quartz decreases rapidly in the first 2 burnings and thereafter much more slowly. By extrapolation, it is estd. that at least 20 burnings under these conditions would be necessary to invert the whole of the quartz. Tridymite increases and cristobalite decreases more in the first 6 burnings than later. The quantity of glass remains const. **III. Determination of the reversible thermal expansion.** *Ibid* 384–7.—**Test pieces were burned up to 12 times in a com. kiln at cone 17, the temp. of the specimens being raised 2.5° per min. The linear expansions for the intervals 15–240° and 15–1000° were, resp.: 1 burn 0.73%, 1.172%; 3 burns 0.74%, 1.130%; 6 burns 0.75%, 1.104%; 12 burns 0.49%, 840%.** H. F. K.

Some effects of firing temperature, kind of grog and grading on the properties of fire-brick material. A. J. DALE. *Trans. Ceram. Soc.* (Eng.) **29**, 326–38(1930).—A clay giving a refractory test result of cone 26 was used as a bond clay with several highly refractory materials. Addns. of over 60% of fused Al_2O_3 or precalcined diaspore gave good results. Greater rigidity of such materials below 1500° can be obtained by increasing the severity of the kiln treatment and decreasing the grain size of the grog. Crude zirconia gave a very dense vitrified product which, however, squatted under load at relatively low temps. Silica glass and quartzitic grog were about equal; the greater the grain size the greater the after-expansion. Vitrified grog should be of finer gradation than the porous grog. When the amt. of clay is not excessive, the value of the clay-bonded refractory is governed by the nature of the grog more than by the clay. H. F. K.

Thermal expansion of refractory materials. R. V. WIDEMANN, A. JOURDAIN AND H. CASSAN. *Ceramique* **33**, 239–56(1930).—Various *types of app.* are described. *Thermal expansion curves* are given for silico-aluminous refractories, French, English and German silica refractories, bauxite and magnesite. A. J. MONACK

The refractory lining of cupolas. JOSEPH ROBITSCHEK. *Feuerfest* **6**, 113–8 (1930).—Lab. tests of refractory brick and examn. under actual working conditions indicate that the major factors in the destruction of a cupola lining are chem. and mech. action of the slag. In some cases the life of a lining depends upon resistance to temp. changes. This factor becomes of greater importance the larger the brick. B. A. SOULE

Electric-furnace production of high-heat-duty refractories. FRED W. SCHROEDER. *Ind. Eng. Chem.* **23**, 124–6(1931).—The operation of the Corhart Refractories Co. is described. Diaspores and kaolins are carefully blended, melted in an elec. furnace of the dipping-electrode resistance type and poured into sand molds, after which the blocks are annealed for 6–10 days. The resulting product is vitreous, non-porous and refractory up to cone 37, has about 0.5 the linear coeff. of expansion of first-class fire brick and is very resistant to the corrosion of glass. H. F. K.

Gas permeability of refractory material, especially at high temperatures. H. IMMKE AND W. MIEHR. *Sprechsaal* **64**, 85–7, 107–9(1931).—Two methods for detg. gas permeability of refractories at high temps. are described. The permeability of 6 pyrometer tubes toward 12 gases detd. at high temps. shows that the gas permeability is directly proportional to the pressure and depends on the temp. At very high temps the gas permeability decreases with increased temp. It is also a function of the viscosity of the gas. C. H. LORIG

The scorification of refractories. V. The relation of flux content and porosity to the scorification of fire brick. HERMANN SALMANG AND OTTO HEBESTREIT. *Feuerfest* **7**, 1–8(1931).—A mixt. of very pure Al_2O_3 and SiO_2 (1:2) was prepd. Portions were treated with a flux (2% of Fe_2O_3, CaO, TiO_2 or Na_2O), molded into cupels and fired at 1410°. Six different synthetic slags were made from mixts. of high-grade FeO, Fe_2O_3, SiO_2, Al_2O_3, CaO and Na_2O. The action of each slag on each sort of cupel for 1 hr. at 1410° showed that, regardless of the flux, the depth of slag penetration was about the same. The max. was 13–14 mm. for the slag 3.46 $CaO.1Al_2O_3.3.53\ SiO_2$. The influence of the flux was nullified by the high porosity (53–54 vol. %). Crucibles made from a 70:30 mixt. of burnt and unburnt kaolin contg. either 0, 2 or 4% flux had a porosity of ±24 vol. %. FeO, as a slag, strongly attacked each type of crucible at 1500°. The action was greatest in the presence of 4% Na_2O or TiO_2. The slag $FeO.SiO_2$ perforated many crucibles. Refractories with 2 or 4% flux were attacked by the various slags only slightly more than those contg. none. Tests on com. brick showed that the action of blast-furnace or open hearth slag is not directly dependent on porosity. Brick of the same chem. compn. and porosity is attacked to the same extent only when the microstructure is the same. B. A. SOULE

Graphical calculation of the composition of ceramic varnishes (CASTIGLIONI) **26.** Firing with powdered coal in German tempering foundries (STOTZ) **9.** Structure of silicates (BRAGG) **6.** Critical observations on the directions for glass testing of the German Pharmacopeia, Sixth Edition (KROBBER) **17.** Transmission changes in ultra-violet glasses during high-temperature exposure to light (NITCHIE, SCHMUTZ) **3.** Heat-treating furnace for enameled articles (U. S. pat. 1,792,284) **9.** Alloys for sealing to glass (Brit. pat. 337,086) **9.** The ternary system: K_2O–CaO–SiO_2 (MORBY, *et al.*) **2.**

Tonindustrie-Kalender, 1931. 2 vols. Berlin: Tonind-Ztg. M. 4. **Reviewed in** *Ceram. Abstracts* **10**, 236(1931).

WIDEMANN, R. V., JOURDAIN, A., AND CASSAN, H.: **L'étude de la dilatation des materiaux refractaires.** Paris: La Céramique. 20 pp. Reviewed in *Ceram. Abstracts* **10,** 236(1931).

Paddle mechanism for circulating molten glass. ALEXANDER F. MCNISH (one-half to John Moncrieff, Ltd.). U. S. 1,792,386, Feb. 10. Structural features.

Apparatus for supplying molten glass to a suction-gathering machine. J. MONCRIEFF, LTD., and A. F. MCNISH. Brit. 336,883, Aug. 9, 1929. Structural features.

Device for gathering molten glass and similar materials. EGYESÜLT IZZOLAMPA ES VILLAMOSSAGI RESZVENYTARSASAG and J. LEVAI. Brit. 335,931, July 2, 1929. Mech. features.

Apparatus and method for circulating and feeding mold charges of molten glass. KARL E. PEILER (to Hartford Empire Co.). U. S. 1,791,634-5-6, Feb. 10. Mech. features.

Forming tubes or rods of glass. P. A. FAVRE. Brit. 336,460, Nov. 14, 1928. App. is described.

Apparatus for glass bottle manufacture. CHARLES BADGER (to Lynch Glass Machine Co.). U. S. 1,792,267, Feb. 10. Structural features.

Coloring glass. DEUTSCHI GASGLÜHLICHT-AUER-GES. M. B. H. Fr. 694,828, May 1, 1930. Glasses are shaded in red with oxides of rare earth metals while preserving the dichroism by adding small quantities of colloidal colors known to color glass red, Au, Cu_2O or Se. Cf. *C. A.* **24,** 5451.

Tempering glass. SOC. ANON. DES MANUFS. DES GLACES ET PRODUITS CHIM. DE SAINT-GOBAIN, CHAUNY ET CIREY. Fr. 695,055, Aug. 7, 1929. An arrangement is described for blowing air on to the heated glass. Fr. 695,040, Aug. 8, 1929. An app. is described for tempering glass. It consists of 2 hollow plates through which cooling liquid flows and between which the sheets of glass are mounted. Cf. *C. A.* **25,** 571, 2, 790.

Glass sheet. Y. BRANCART. Brit. 336,921, Feb. 14, 1929. Mech. features relating to the formation of the sheets (or their immediate treatment after formation) with a rotating rough roller run at such a speed that the glass is driven backward slightly toward the beginning of the plate. The impressions formed disappear at once. Brit. 336,924 relates to a generally similar process including rolling with smooth rollers. Cf. *C. A.* **25,** 571.

Table for receiving or casting glass plates or sheets. C. LOCKFELLER. Brit. 336,550, April 9, 1929. Casting tables are made of a sandless concrete composed of fragments of porphyry and of a cement formed of a ground mixt. of burned lime, silica and alumina (the porphyry fragments being distributed in several layers through the thickness of the table in graded sizes with pulverized porphyry in the top layer).

Apparatus for making sheets of glass. MISSISSIPPI GLASS CO. Fr. 693,940, April 15, 1930.

Apparatus for rolling sheets of glass. N. V. MAATSCHAPPIJ TOT BEHEER EN EXPLOITATIE VAN OCTROOIEN. Fr. 693,973, Apr. 4, 1930.

Rolling and fire-polishing glass sheets. A. BRANCART. Brit. 336,533, Feb. 25, 1929. App. and various details of procedure are described.

Plate glass rolling machine. N. V. MAATSCHAPPIJ TOT BEHEER EN EXPLOITATIE VAN OCTROOIEN. Ger. 513,879, Nov. 29, 1929.

Sole plate for glass-annealing furnaces, etc. YVON BRANCART. U. S. 1,791,656, Feb. 10.

Furnace for annealing glassware. W. A. MORTON. Brit. 336,596, April 15, 1929.

Apparatus for making glass reënforced with wire. MISSISSIPPI GLASS CO. Fr. 694,215, April 19, 1930.

Safety glass. JOHN NEWTON. Fr. 693,919, April 15, 1930. Safety glass is made by incorporating 2 or more sheets of celluloid or cellulose acetate, etc., between 2 sheets of glass.

"Unsplinterable glass" sheets. T. W. HOLT and J. F. W. STUART. Brit. 336,037, Aug. 1, 1929. Various details of app. and procedure are described for uniting the component sheets with use of fluid pressure in an autoclave.

Uniting glass sheets with non-brittle material. LIBBEY-OWENS GLASS CO. Brit. 336,732, Aug. 30, 1929. In uniting glass sheets with cellulose derivs. or synthetic resins or with a combination of the two, the latter is sprayed with a bonding medium such as a mixt. of di-Bu phthalate and a polyglycol deriv. such as the monoethyl ether of diethylene glycol, and the sheets are united by heat and pressure. The glass may be sprayed with a cellulose deriv. compn. or synthetic resin compn. in a low b. p. solvent

mixed with higher b. p. solvent or plasticizing substances. Various details of procedure and compns. are given.

Uniting glass sheets with sheets of cellulose derivatives. S. BARRATT. Brit. 335,890, June 29, 1929. For removal of knife marks and the like, a cellulose deriv. sheet is softened and pressed with a hard surface (which may be a gelatin-coated glass sheet with which it is to be united). Various details of heating and pressing the sheets together are described.

Joining glass sheets with an intervening sheet of celluloid or similar materials. T. W. HOLT and J. F. W. STUART. Brit. 337,158, Oct. 2, 1929. Various mech. details for uniting the sheets are described.

Composite sheets of glass and cellulose derivatives. BRITISH CELANESE, LTD. Brit. 335,878, March 13, 1929. Two glass sheets are united by an intermediate sheet formed of a cellulose deriv. and an org. tartrate such as di-Bu or di-Et tartrate and dyes, synthetic resins and stabilizers such as urea also may be added. The cellulose deriv. sheet may be united to the glass by an adhesive such as gelatin or vinyl acetate resin or a suitable mixt. of a cellulose deriv. and synthetic resin.

Fused silica sheets suitable for window panes. J. H. SULLIVAN (to British Thomson Houston Co., Ltd.). Brit. 336,923, Feb. 14, 1929. Fragments of cryst. SiO_2 are fused *in vacuo*, the material while plastic is allowed to assume, by gravity, the form of a flat sheet, and is caused to harden under gaseous pressure, as by admitting air or by use of N under pressure (suitably 200 lb. per sq. in.). App. and various details of procedure are described.

Purifying clay. WM. FELDENHEIMER. U. S. 1,791,959, Feb. 10. A liquid suspension of the material is deflocculated, impurities are sepd. (as by sedimentation) and the slip is flocculated and thickened with reagents such as lime and HCl in quantities which render the clay non acidic, and the clay is sepd. from the liquid.

Refining kaolin and clay. ERICH MÜLLER. Ger. 516,144, Dec. 30, 1926. Water and water glass in const. proportions are continuously fed to a mixing vessel to which kaolin or clay is also fed at such a rate that a suspension having a sp. gr. between 1.08 and 1.09 is produced. It is stated that a streaky appearance develops on the surface of the suspension when the sp. gr. lies between the limits mentioned. The suspension flowing from the mixing vessel is passed upwardly through a funnel-shaped vessel to remove fine impurities, and then neutralized with HCl and worked up in known manner. Cf. *C. A.* **25**, 783, 790.

Porous bricks. T. KOIDL and F. GORLICH. Brit. 337,231, Nov. 20, 1928. An extrusion press is provided with means for injecting compressed air into the plastic material for forming the bricks before the material is fed to the extrusion nozzle.

Heat-insulating bricks, etc. SIEBCHAMOTWERKE G. M. B. H. Ger. 516,377, June 8, 1926. Porous bricks, etc., are evacuated and then coated with a material impermeable to gas, *e. g.*, rubber. The coating may be partly applied before evacuation.

Rotary ceramic furnace. GEORG VON HERITZKA. Ger. 513,583, May 12, 1929. The bearing stones are partly of high Al_2O_3 content, and partly of chamotte stone.

Ceramic kiln. JEGOR I. BROWN. Ger. 513,581, July 28, 1926. An electrically heated tunnel kiln for firing ceramic ware at high temps. and with pre-heating, firing and cooling zones is described.

Burning ceramic sludge. LEOPOL, INTERNATIONALE PATENTVERWERTUNGS G. M. B. H. and N. V. "SOLOPOL" INGENIEURSBUREAU TOT EXPLOITATIE VAN HET, SYSTEM POLYSIUS. Ger. 513,584, Sept. 7, 1927. Ceramic sludge, especially crude cement sludge, is wholly or partly dried, heated in a rotary furnace until granulated, calcined and finally sintered.

Molding fused quartz. DEUTSCH-ENGLISCHE QUARZSCHMELZE GES. Brit. 336,493, Dec. 12, 1928. In forming articles such as insulators or tubes with ribs or flanges, a hollow blank of the material is expanded in a mold by compressed air and then further shaped by application of pressure mechanically.

Apparatus and hydraulic classification system for grading abrasives such as those used in continuous glass-grinding apparatus. PILKINGTON BROS., LTD., F. B. WALDRON and J. H. GRIFFIN. Brit. 336,587-8, July 12, 1929.

Abrasive wheel. JOHN R. GAMMETER (to George W. Perks Co.). U. S. 1,792,083, Feb. 10. An abrasive wheel body is formed with spiral grooves in its opposite faces, and wire convolutions are wound while hot in the grooves and permitted to shrink in them, and over these a bonding layer of material such as a rubber or synthetic resin compn. is cured under pressure to secure the wire convolutions to the face of the wheel.

Compositions for grinding-wheels. CARBORUNDUM CO. Brit. 336,631, July 17,

1929. A cement formed of S 95 and ground coke 5% is used in building up wheels of segmental abrasive blocks (various structural details of which are given).

Refractory earth. FELLNER & ZIEGLER A.-G. Fr. 694,818, May 1, 1930. Refractory earth is baked in a rotating tubular furnace at temps. of 1100–1300° and the furnace is preferably enlarged in the 800–1000° zone.

"Semi-porcelain" composition. J. E. TAMS. Brit. 336,172, Dec. 27, 1929. Asbestos powder 50, ball clay 40 and either ground stone 20 or feldspar 20 (or of each 10) parts are blunged with water into a slip or plastic mass for treatment in the usual way.

Enamels. W. E. DOUGHERTY. Brit. 336,797, Oct. 17, 1929. TiO_2 is used as an opacifier in enamels which do not contain F, and $CaCO_3$ or other suitable salt of Ca, Ba, Sr or Mg is preferably added to the batch to intensify the opacity produced by the Ti. Small quantities of Zr or Sn oxides may be added to counteract any tendency to yellowish color. Various details are given.

Coloring enamel, glass, etc. DEUTSCHE GASGLÜHLICHT-AUER-GES. M. B. H. Fr. 694,888. May 2, 1930. To obtain red colored enamel, glass or glazes with Se, use is made of enamel, etc., which has a high content of rare earths. Cf. *C. A.* 24, 5451.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Quinquennial review of the mineral production of India for the years 1924 to 1928. Cement. A. M. HERON. *Records Geol. Survey India* **64**, 359-70(1930).—The Indian cement industry has increased materially each yr. Several companies use a limestone which naturally contains the correct proportions of clay. **Building materials.** E. H. PASCOE. *Ibid* 347–59. **Marble.** *Ibid* 406-9.—Marbles of all colors are plentiful in India. **Slate.** E. L. G. CLEGG. *Ibid* 429–31 ALDEN H. EMERY

Electro-melted cement as a new building material in the chemical industry. CONSTANTIN REDZICH. *Apparatebau* **42**, 277-8(1930).—The manuf. of a cement from bauxite and burned lime in an elec. furnace is described. The product has the following approx. compn.: Al_2O_3 35–50, CaO 35–45, Fe_2O_3 5–15, SiO_2 5–10%. It is compared to portland cement and may supplant it. M. C. ROGERS

Blast-furnace-slag portland cement. GIUSEPPE TOMARCHIO. *Atti III congresso nas. chim. pura applicata* **1930**, 557–60.—Compn. and properties of various slag cements are reviewed. E. M. SYMMES

Potash salt recovery in cement burning, with special reference to Esthonian potash ores. JAAK KUUSK. *Acta Commentationes Univ. Tartuensis (Dorpatensis)* **AXX**, No 4, 1–36(1930)(in German).—Esthonia contains relatively large amts. of K ores capable of being burned to cement. In burning, K compds. are volatilized in part and can be pptd. electrostatically. Since the K compds. in different cement plants volatilize quite differently, and since the factors affecting the volatility are not known accurately volatilization of K compds. was investigated in the lab. In a mixt. of K silicate with $CaCO_3$, in the ratio $2CaO \cdot SiO_2$, decompn. of K silicate and volatilization of K began simultaneously at about 1150°. With increasing temp. and duration of heating the amt. of K volatilized increased per unit of time. If less $CaCO_3$ were added to the K silicate than corresponds to Ca metasilicate, volatilization of K stops almost wholly even at very high temp. Starting from these mixts., the volatility of K increases rapidly with increase in amt. of $CaCO_3$ added. Addn. of Fe_2O_3 affects K volatility very favorably because it increases the velocity of K silicate decompn. at low temp. The Fe_2O_3 added remains almost unattacked. Addn. of Al_2O_3 is unfavorable to K volatility because most of the CaO present changes to aluminate. Addn. of $CaSO_4$ is just as effective as addn. of $CaCO_3$. In K volatilization from synthetic K aluminate the same general results were obtained. The amt. of K volatilized at 1440° was low if only sufficient $CaCO_3$ were added to the aluminate to form only Ca meta-aluminate. (Ca or K_2)SiO_3 and (Ca or K_2)$2AlO_2$ are unstable at the roasting temp. in question, while (Ca_2 or K_4)SiO_4 and (Ca_2 or K_4)$2AlO_2$ are unstable and lose K_2O. E. M. SYMMES

Hydrated lime as used in engineering. R. J. HOLDEN. *Eng. News-Record* 106, 148–9(1931).—Curves are given showing the total annual production of CaO and $Ca(OH)_2$ during the period 1906–1928 and the amts. used for building during this period, together with a brief discussion of the properties of CaO and $Ca(OH)_2$, with particular reference to deterioration on storage. There has been no increase in the production of CaO since 1906, but the production of $Ca(OH)_2$ has markedly and steadily increased. R. E. THOMPSON

A study of methods of curing concrete pavements. Report of field investigation in Tennessee. F. H. JACKSON AND E. W. BAUMAN. *Public Roads* **11**, 209–35(1931).—The method of cure involving the application of wet burlap for periods varying from 24 to 96 hrs. without further curing compares favorably with the standard method. The application of Sisalkraft paper for periods of 24 to 48 hrs. without further curing is a reasonably satisfactory method of cure as compared with the standard method. In the poor earth cure it is not necessary to keep the earth satd. with water for the entire 10-day curing period. The sodium silicate method of cure gives results somewhat less satisfactory than those given by the standard method. Surface application of $CaCl_2$ appears to give results nearly as satisfactory as the standard method. Curing with bituminous materials, as used in these tests, was unsatisfactory; there was marked evidence of increased transverse cracking. Nothing is gained by the use of tar paper on the subgrade.
L. B. MILLER

Revision of "Directions for testing (D I N 1995) and delivery (D I N 1996) of road and construction materials containing asphalt and tar." ANON. *Asphalt u. Teer* **30**, 1253–62(1930).
K. H. ENGEL

Testing limestone for road building. J. JACHZEL. *Asphalt u. Teer* **30**, 1041–2 (1930).—Soly. in CO_2-contg. water (indicative of grain size) and mech. hardness should be detd. The presence of $Ca(HCO_3)_2$ is a proof of harmful weathering. K. H. E.

American road tars. HUGO LAEGER. *Brennstoff-Chem.* **12**, 89–90(1931).—Comparison of grades, consumptions and prices with corresponding German products.
F. W. JUNG

German patent development in bitumen emulsions for road construction. A. VON SKOPNIK. *Teer u. Bitumen* **28**, 581–5(1930).
K. H. ENGEL

Road asphalt and mechanical methods for testing it. W. BIERHALTER. *Asphalt u. Teer* **30**, 931–46(1930).
K. H. ENGEL

Preparation of a new road binder. C. F. BROADHEAD. Inst. Gas Eng., *Communication* No. **3**, 23 pp.(1930).—See *C. A.* **24**, 4372.
G. G.

Determination of wool content in roofing felts by chemical methods. R. KORN AND B. SCHULZE. *Teer u. Bitumen* **29**, 34–6(1931).—Admixed wood flour is insufficiently dissolved during treatment of the felt with 80% H_2SO_4. Shaking during the digestion reduces the residue to 6%. A felt sample equiv. to 10 g. dry, ash-free material is boiled in H_2O and macerated. The fibers, isolated and washed with alc., are shaken with 300 cc H_2SO_4 (80%) for 3 hrs. The acid is removed with H_2O and dil. NH_3 and the residue dried at 100–5°. Ash and, if warranted, 6% of the wood flour content are deducted from the wool residue. The wood flour of the felt should be estd. microscopically in ranges of 10%.
K. H. ENGEL

New methods of wood utilization and wood research. HANS WISLICENUS. *Z. Ver. deut. Ing.* **74**, 1469–78(1930).—A short outline of wood chemistry is followed by details of kiln drying, impregnation, wood decompn. processes, surface charring to enhance the grain effect, liquid infusion of living trees, turpentine recovery, wood cellulose, saccharification, artificial silk and metallized wood.
E. M. SYMMES

Protecting wood from fungi (Brit. pat. 336,244) **18.**

Cement. EMIL REUBKE (to I. G. Farbenind. A.-G.). U. S. 1,791,684, Feb. 10. See Fr. 662,145 (*C. A.* **24**, 482).

Cement. TREVOR M. CAVEN (to Frederick B. Hazard). U. S. 1,791,591, Feb. 10. A cement in dry powd. form suitable for monolithic linings or walls comprises about 5% silica in colloidal form, about 10% silica in diatomaceous form and about 85% silica in relatively coarse form, all these forms of silica being of approx. the same compn.

Dolomite cement. GUSTAV MATSCHAK. Ger. 500,138, Mar. 25, 1928. $MgSO_4$ is added to the product in order to react with any CaO formed during the firing and at the same time to raise the Mg content.

Portland cement. JAMES H. COLTON (to Pacific Portland Cement Co.). U. S. 1,791,800, Feb. 10. A portland cement mixt. is burned to form a clinker, the clinker is ground, the ground clinker is added to a raw cement mix to form a granular mixt. and this mixt. is burned to form a clinker.

Waterproof cement. S. A. I. G. (Soc. ANON. INVENZIONI GUADAGNIN). Brit. 336,860, Dec. 9, 1929. See Fr. 686,193 (*C. A.* **25**, 566).

Composition for waterproofing cement. SAM C. BENNETT. U. S. 1,791,704, Feb. 10. A mixt. formed from Na_2CO_3 9, $Al_2(SO_4)_3$ 1, $KMnO_4$ 0.03 and water about 20 parts is used together with pure cement in sufficient quantity to leave the compn. fluid so that

it may be applied as a liquid coating to waterproof and "rejuvenate" worn and discolored cement.

Rotary kiln for the preparation of fusible cement. ARNO ANDREAS. Ger. 513,582, Feb. 7, 1929.

Apparatus for granulating crude material and burning to produce cement. OTTO LELLEP. Ger. 515,172, Feb. 10, 1929. Addn. to 466,298 (*C. A.* **23**, 497).

Hydraulic product. KARL BIEHL. Fr. 695,079, May 5, 1930. A hydraulic product for addn. to lime, cement, etc., is made by heating all sorts of clay, marl products of volcanic eruption, etc., and fine grinding.

Concrete. LUDWIG HEYNEMANN. Fr. 695,099, May 5, 1930. A concrete which is resistant to sea-water is made by adding to ordinary or superior cements or mixts. of these with sand, etc., finely divided cinders from the combustion of powd. coal.

Concrete composition. CARLTON E. MILLER. U. S. 1,791,630, Feb. 10. A concrete which sets quickly to a high strength is formed from an admixt. of portland cement with a preformed mixt. comprising $CaCl_2$ 2 and diatomaceous earth 3 parts (suitably 5% as much of this mixt. as of portland cement).

Cellular concrete. TORKRET-GES. M. B. H. Fr. 694,287, April 22, 1930. A liquid absorbing substance such as kieselguhr is added to cellular concrete so that the mass is plastic without losing its swelling power.

Cellular or porous concrete. EMRIK I. LINDMAN (to Aerocrete Corp. of America). U. S. 1,791,820, Feb. 10. Cement and water are mixed with a metal powder which is adapted to cause generation of gas and with slag so divided as to present fine hydraulizing particles and larger particles of a size and in sufficient quantity to prevent formation of cracks during setting (the slag not exceeding 80% of the wt. of the total dry ingredients of the concrete, and at least 10% having a grain size less than three-eighths of an in.).

Casting concrete pipes. ABRAHAM RUTENBERG. Ger. 516,437, May 17, 1929. See Brit. 318,285 (*C. A.* **24**, 2266).

Dust-laying agent for roads, etc. FRITZ LYDTIN. Ger. 513,846, May 15, 1925. Low-temp. tar (*e. g.*, generator tar, crude mineral tar, etc.) from brown or stone coal is used, alone or mixed with other residues or distn. products.

Asphalt or tar compositions. I. G. FARBENIND A.-G. Fr. 694,789, May 1, 1930. Asphalt, tar or bitumen compns. for roads, paint, etc., contain appropriate polymerization products of diolefins.

Colored mineral granules suitable for decorating roofing shingles. RALPH L. ATKINSON (to Arthur D. Little, Inc.). U. S. 1,792,058, Feb. 10. Material such as compacted raw clay or shale is reduced to granules of the desired size, these are separated from material of finer size or dust, treated with water or a coloring agent such as Fe, Cu, Mn, Co or Cr compds. if required, and heated to a hardening temp. without fusion.

Artificial stone, etc. ÖSTERREICHISCH-AMERIKANISCHE MAGNESIT A.-G. and KONRAD ERDMANN. Austrian 120,418, July 15, 1930. Addn. to 108,151. In the manuf. of shaped articles from fibrous materials and a Sorel cement, the compn. is bound and hardened in the mold by means of a gas heated to a temp. between 220° and 450°. Open, closed or perforated molds may be used, and the gaseous atm. may contain CO_2. Cf. *C. A.* **24**, 4913.

Mold for casting plates from a mixture of magnesite, magnesium chloride solution and powdered stone or quartz. MICHAEL GUTTENBERGER. Ger. 516,066, Aug. 23, 1927.

Molded material resembling wood, etc. A. HAWERLANDER (to Halizite Corp.). Brit. 336,754, March 13, 1929. Fibrous material such as sawdust is first treated with a small quantity of a volatile liquid such as "petrol," is then incorporated with sufficient phenol-CH_2O resin condensation product to cover its surface and is molded under heat and pressure so as to permit venting of the volatile liquid before the binding agent hardens. The material may be molded in contact with surface veneers of wood. Various details of procedure are described.

Preservative for wood. HOLZINDUSTRIE-WERKE JOSEF BENZ A.-G. Ger. 516,407, Dec. 14, 1929. Asphalt-rubber melts are dissolved in a mixt. of acetone oil with homologs of benzene and (or) with hydronaphthalenes.

Preserving wood. LEO PATRICK CURTIN. Ger. 516,075, Mar. 12, 1927. See Brit. 291,857 (*C. A.* **23**, 1241).

Impregnating wood. IMPREVA HOLZIMPRÄGNIERUNG UND HOLZVERWERTUNG A.-G. Ger. 513,848, Jan. 16, 1925. The bottoms of masts are treated with a soln. of bitumen, pitch, etc., in CCl_4.

Apparatus for impregnating wood with creosote and for compressed air or steam treatment. C. GOODALL. Brit. 337,133, Sept. 18, 1929. Structural features.

Apparatus for the partial impregnation of wooden masts or poles. ERNST REICH and LUDWIG TRAMER. Austrian 120,412, July 15, 1930.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND ALDEN H. EMERY

Quinquennial review of the mineral production of India for the years 1924 to 1928. Coal. CYRIL S. FOX. *Records Geol. Survey India* **64**, 31–78(1930).—Complete statistical data for production and handling of Indian coal from 1919 to 1928 are given. Typical coal analyses are given. Coal reserves are estd. ALDEN H. EMERY

The evolution of coal. HENRY BRIGGS. *Chemistry and Industry* **50**, 127–33 (1931).—Coal of all varieties has undergone and is still undergoing a species of slow spontaneous change involving the discharge of CH_4 and H_2O. B. calls this autometamorphism. It may proceed entirely independently of outside influences, although heat (mild) and pressure accelerate, and certain influences, such as a large quantity of mineral matter, retard the action. The continued evolution of CH_4 from coal is confirmatory proof of this reaction. Analyses of coal of all ranks, ash-, S- and N-free, are plotted on a C-H-O trilinear diagram. The gaseous evolution necessary to move from one rank of coal to another is calcd. ALDEN H. EMERY

Bibliography of United States Bureau of Mines investigations on coal and its products, 1910–1930. A. C FIELDNER AND M. W VON BERNEWITZ. Bur. Mines, *Tech. Paper* **493**, 56 pp.(1931).—Over 750 references to articles on coal and coal products by members of the staff of the U. S. Bureau of Mines are classified and cross-indexed. The subjects covered include origin, constitution, analyses and classification of coal; chem. and phys. properties of coal and coke; absorption and evolution of gases in coal; corrosion and mine water; coal-dust inflammation; methods of sampling, analyzing and testing; mining; coal prepn.; storage and spontaneous heating; processing, including briquetting, high-temp. and low-temp carbonization; utilization, including combustion in power boilers, domestic furnaces, locomotives, marine boilers, kilns and oil stills; smoke abatement; lignite; and economics and statistics ALDEN H. EMERY

The primary oxidation of bituminous coal. W. FUCHS AND O. HORN. *Brennstoff-Chem.* **12**, 65–7(1931); cf. *C. A.* **23**, 1403; **24**, 4767; **25**, 396.—For conversion into humic acids, the humins of bituminous coals have been readily oxidized in a short treatment with HNO_3 (sp. gr. 1.40). The products possess the characteristics of hydroxy carboxylic acids, form permutite like K salts and ether-esters. They are partly sol., especially when damp, in org. solvents, as pyridine, acetone, "methylglycol," but are not always peptizable in alkalies. The peptized acids are identical with the original except for a difference in soly. (also produced by a H_2O-pyridine treatment) and a 20% greater K content in their K salts. The humin content of striped (bituminous) but not anthracite or boghead coal may be made water-sol. in this way. F. W. JUNG

The present status of low-temperature carbonization technic. CH. BERTHELOT. *Rev. métal.* **27**, 672–9(1930).—From the standpoint of its present development in England and Central Europe low-temp. carbonization is faced with 3 major difficulties: (1) high cost of production, which in some cases is 3 times that of high-temp. coke; (2) little profitable disposal of the primary tars in other than the fuel markets; and (3) the competition following new methods of utilizing high-temp carbonization gas. Hydrogenation and cracking methods are promising for increasing the value of the tars H. L. OLIN

Preparation of fiber coal (fusain) through artificial carbonization. TH. LANGE AND P. ERASMUS. *Braunkohle* **29**, 463–9(1930).—Samples of silicified lignite with well-preserved cell structure (trunk and roots) were carbonized by heating under water at 340° for 2 hrs. SiO_2 was leached out with H_2F_2. Microscopic slides showed that the org. material had been carbonized to *fusain*. Isolated cellular aggregates, filled with bituminous material, had changed to *vitrain*. Conclusion: Cell walls filled with humic acids were gradually resorbed and changed to vitrain. Wood which was filled with gases, SiO_2, etc., or which had lost its permeability to humic acids through drying, retained its structure and was carbonized to fusain. K. H. ENGEL

Relation between the contents of coal in volatile matter and in ash (supplementary note). M. LEGRAYE. *Ann. soc. geol. Belg.* **53**, B55–7(1930).—Replying to a criticism of Denoel of a previous paper (*C. A.* **24**, 710), L. gives more curves and discussion. He finally concludes that there is no relation between ash content and content in volatile matter, and that no conclusions can be drawn regarding the comparative origin of bituminous and anthracite coals. R. H. EWELL

The relation between gross and net heating values and volatile matter of coal. WILHELM GUMZ. *Feuerungstech.* **19**, 1–3(1931).—From 100 analyses in the literature G. derives the formulas: $Q = 8150 + 6543V - 17{,}308V^2$ and $H = 8150 + 4489V - 13{,}864V^2$ for the gross and net heating values, resp., of the dry ash-free coal, V being the fraction of this which is volatile. ERNEST W. THIELE

Diffusion as a factor in burning pulverized coal. DOUGLAS HENDERSON. *Power* **73**, 288–9(1931).—While the mixing of air with a gaseous fuel is in part by diffusion, macroscopic fuel particles must be mixed mechanically with air. D. B. DILL

Testing coking coals. WOLFGANG MELZER. *Arch. Eisenhüttenw.* **4**, 169–75 (1930).—A no. of tests are outlined for Westphalian coking coals. For works labs., extn. methods are too time-consuming, and sufficient information as to the coking qualities can be obtained by detn. of the softening point. H. STOERTZ

Asturian coals. III. Rejuvenation of a gas coal. BENITO A. BUYLLA. *Anales soc. españ. fís. quím.* **28**, 959–66(1930); cf. *C. A.* **24**, 2860.—In "berginizing" a coal having volatil ematter 32% (yielding highly swelled coke 66.38 and primary tar 5.8%), 22.2% oils and 64% solid residue were obtained. The residue contained volatile matter 28.94% and produced hard, coherent coke 59.54 and primary tar 9.41%. This indicates the possibility of rejuvenating coal by hydrogenation. E. M. SYMMES

Coal as a raw material. E. F. ARMSTRONG. *Chem. Markets* **28**, 158–60(1931).—A plea is made for the most efficient means of utilizing coal, coke, oil, etc. Hydrogenation after carbonization of the coal under conditions assuring a max. yield of oil and a char which may be used in the manuf. of water gas and H_2 appears economically best. W. H. BOYNTON

Humic acids from brown coal. Preliminary communication. HANS STACH. *Z. angew. Chem.* **44**, 118–20(1931).—Not only humic acid but also brown coal from which the bitumen has been extd. can be methylated. The ability to react with diazomethane proves the acid character of the extd. coal. A distinction is made between ortho- and meta-humic acids, the latter not being sol. in cold KOH. E. SCHOTTE

Recent developments in by-products from bituminous coal. A. C. FIELDNER. Bur. Mines, *Rept. of Investigations* 3079, 13 pp.(1931).—There has been steady gain in value and yield of by-products from coal during the last 15 yrs.; the design of ovens and by-product recovery equipment has also shown const. improvement. The by-product oven has recently supplied much base-load gas for city use. Natural gas and refinery gas are increasingly important competitors. Cheap synthetic NH_3 has made the profitable recovery of by-product NH_3 a problem. The Tern and C. A. S. processes for the conjoint recovery of S, NH_3 and cyanogen, European developments and the recovery of by-product S peculiarly adapted to fungicidal and agricultural purposes as practiced in America are described. The solution of the phenol recovery problem and the reduction of light-oil losses by improvements in refining are discussed. ALDEN H. EMERY

Concretions in coal. X. STAINIER. *Ann. soc. sci. Bruxelles* **50**, Ser. B, 247–55 (1930).—The formations known as "coal apples" found in English pit-coals and in certain anthracite coals of the U. S., nodules found in Australia, ball coal in pit-coal of Hindustan and certain concretions found in Belgium are described. S. states that no decisive proof of the origin of these structures is available from these studies. The phenomenon is probably more complex than one thinks and may be due to a combination of causes. Even the term concretions is used for want of a better word. They are not true nodules, produced by concn. at a given point, of substances at first scattered through a rock. Various possible theories are discussed. ALICE W. EPPERSON

Coal-cleaning problems. L. W. NEEDHAM. *Iron Coal Trades Rev.* **121**, 525–7 (1930).—A review. LESLIE B. BRAGG

The hydrogenation of solid fuels. CARL ZERBE. *Chem.-Ztg.* **55**, 4, 18–9, 38–40, 94–6, 114–7, 136–7, 152–3(1931).—A review of the present status of the process, with particular reference to recent patents, and extensive bibliography. T. H. CHILTON

Fusion points of the ash constituents of the Sonnenschein seam. H. WINTER AND H. MÖNNIG. *Glückauf* **67**, 156–60(1931).—Fusion points of ash from different structural parts of the Sonnenschein seam detd. by the methods of Bunte and Baum (*C. A.* **22**, 1457) and of Dolch and Pochmuller were: fusain 1060 1150°, vitrain 1125–1200° and durain 1530°. In every case as the compn. of the ash approached that of pure clay, $Al_2O_3.2SiO_2.2H_2O$, the m. p. was raised. H. L. OLIN

New researches on ash fusion points. C. STAEMMLER. *Chem.-Ztg.* **55**, 59–60 (1931).—Various Ca, Fe and Si salts were combined into mixts. and the fusion points detd. by thermocouples after the method of Bunte and Baum (*C. A.* **22**, 1457). Sulfates always raised the fusion points of the mixts., probably because of some interaction between S and the oxides. C. R. FELLERS

Furnace heating by means of pulverized fuel. G. E. K. BLYTHE. *Metal Ind.* (London) **34**, 177–9, 231–2(1929). E. J. C.

At what temperature should purification masses be dried? DE VOOGD. *Het Gas* **50**, 501–5(1930).—Expts. on drying of $Fe(OH)_3$ were conducted to det. the correct drying temp. for purification masses. Even at 110° not all water is removed after drying for a long time because of the colloidal character of the hydroxide and the lack of a definite hydrate. This holds for Lux mass as well as for the weathered limonite which is used as a natural product. Every drying temp. is arbitrary. The method outlined is as follows: Weigh at least 1 kg. of substance in a flat dish and place in a drying furnace at 60–70°. After 2–8 hrs. take out the dish and expose to air for 15–16 hrs. (overnight). Repeat the cycle of heating, aeration and weighing (usually thrice) until const. wt. (within 1%) is obtained. The analyses for Fe of the mass should be related to the original wt. and not calcd. on dry wt. This is also true for the absorption capacity detn. for H_2S (generally 74% by wt. of the Fe present, 16% of the mass itself). B. J. C. VAN DER HOEVEN

Alcohol as motor fuel. Report on practical large-scale tests. P. W. UHLMANN. *Chem.-Ztg.* **54**, 818–9(1930).—A suitable substitute for gasoline used in Brazil in 1916 consisted of a mixt. of abs. EtOH, Et_2O and petroleum in the wt. proportions 75:15:10. R. E. SCHAAD

Alcohol production for motors in Brazil. FREDERICO W. FREISE. *Intern. Sugar J.* **32**, 404(1930).—In recent years much work has been done on the utilization of molasses for the manuf. of motor spirits. One plant with a capacity of 100 tons of motor alc. is operating at its full capacity. In a test of "Azulina," a national motor spirit containing 57% ether, on a motor car fitted with 2 T. A. G. motors of 100 h. p. each, av. fuel consumption was 1.4 l. "Azulina" per km., while the gasoline consumption in parallel tests was 1 l. per km. The price of "Azulina" is half that of gasoline. W. L. OWEN

Suitability of fuels for Diesel engines. LOUIS R. FORD. *Power* **73**, 361–3(1931).—Since the factors which control the behavior of fuel in the engine cylinder are not well understood, performance tests must be relied upon in selecting suitable fuels. D. B. DILL

Hydrogenation at high pressures. GIORGIO ROBERTI. *Mem. accad. Italia* (*Classe sci. fis. mat. e nat.*) **1**, Chim. No. 2, 15 pp.(1930).—As part of the general problem of utilizing national sources of fuels, the hydrogenation of the phenolic distillate from lignite was studied. Co_2S_3 was found to be a satisfactory catalyst, as it induces the formation of satd. cyclohexane at 100 atms. at temps. of 350–400°, and, at the same time, is much less sensitive to poisoning than other commonly employed catalysts. A. W. C.

The possibilities of a South African oil industry. O. FELDMANN. *S. African Mining and Eng. J.* **41**, Pt. II, 281–2(1930).—F. discusses the low-temp. carbonization of S. African lignite followed by hydrogenation of the tar produced. A. H. E.

The history of gas. C. L. VAN BALEN. *Het Gas* **51**, 40–6(1931). B. J. C. v. d. H

The Linz gas works—its development and its future position. LUDWIG STOLL. *Z. österr. Ver. Gas Wasserfach.* **71**, 30–40(1931). E. H.

Nomography in gas analysis. W. J. G. DAVEY. *Gas World* **92**, 694–5(1930).—The graphical method is used for the detn. of H_2 and CH_4 in a gas after the other constituents and the calorific value have been detd. The other constituents usually detd. are CO_2, O_2, unsatd. hydrocarbons, CO and N_2. Examples are given showing the application of the method to carbureted water gas and vertical retort gas. F. H. B.

Institution gas research fellowship report 1929–30; influence of the inorganic constituents in the carbonization and gasification of coal; liberation of ammonia. A. H. EASTWOOD AND JOHN W. COBB. Inst. Gas Eng., *Communication* No. **23**, 24 pp.(1930).—See *C. A.* **25**, 1057. G. G.

Heat transmission: modern methods of expressing convection data. M. FISHENDEN. *Gas World* **92**, 632–7(1930).—The principles of heat transfer are reviewed and expressed in math. form. Many heat transfer problems connected with the gas and carbonization industries are too complex to be expressed in simple generalized rules. In some individual cases it is possible to correlate and apply available data. The math. presentation is supplemented with graphs for the solution of heat-transfer problems, particularly those in which convection is taken into account. F. H. BERGEIM

Gas meter calibration with the Mariotte bottle. L. ZIPPERER. *Gas Wasserfach* **74**, 27–8(1931).—An insulated Mariotte bottle is a convenient means for calibrating

gas meters. An illustration of such use and the method of calcg. exact gas vols. are given with examples. R. W. RYAN

The new (large) Brandl-Marischka gas meter. PITTSBURGH EQUITABLE METER CO. *Gas u. Wasserfach* **74**, 67(1931); cf. *C. A.* **24**, 5135.—The principle of the Brandl-Marischka meter is old and has long been used by the Pittsburgh Equitable Meter Co. **Reply.** BRANDL AND MARISCHKA. *Ibid* 67–70.—Patents granted in various countries are listed. R. W. RYAN

Coal-grinding and -mixing equipment for gas works. Otto HUPPERT. *Gas u. Wasserfach* **74**, 49–56(1931).—When gas works are large enough there is a definite advantage in grinding and blending coal, as cheaper coal and waste coal and coke can be used and a good coke still obtained. Operating and test data are given in support of this claim and a typical German installation is illustrated and discussed. Attempts to use low-temp. brown-coal coke in such blends were unsuccessful. Recent work of Damm, Fischer and others on the mechanism of coking is reviewed R. W. RYAN

The physical basis and the manner of operation of the Progas-Union gas governor. C. BARCKMANN. *Gas u. Wasserfach* **74**, 110–2(1931); cf. *C. A.* **25**, 190.—Addns. and correction to previous math. derivations are given R. W. RYAN

Gas dehydration. E. W. SMITH. Inst. Gas Eng., *Communication* No. **5**, 37 pp. (1930).—See *C. A.* **24**, 4917. G. G.

Effect of sodium carbonate upon gasification of carbon and production of producer gas. DAVID FOX AND ALFRED H. WHITE. *Ind. Eng. Chem.* **23**, 259–66(1931).—Na_2CO_3 reacts in appreciable measure with C at temps. above 800° and the rate becomes rapid above 900°. The reactions are $Na_2CO_3 + 2C = 3CO + 2Na$, $Na + CO = NaO + CO$; $NaO + CO_2 = NaCO_3$. The net effect is to increase the vapor pressure of C to 10^{15} times its actual value. The mechanism of the reaction is discussed. The use of coke impregnated with Na_2CO_3 in the gas producer gives gases higher in CO than would otherwise be obtained. In a water-gas machine the gases are much richer in CO and H_2, but the increased reactivity of the fuel bed would be disadvantageous during blasting and offset any gains during steaming ALDEN H. EMERY

The new Omeco flue-gas tester. ILLIES. *Feuerungstech.* **18**, 242–3(1930).—The recorder dets. O_2 instead of CO_2. An automatic device takes in predetd vol. of the sample and of H_2 and passes them through a combustion furnace. The contraction is recorded. ERNEST W. THIELE

A new method of phenol recovery from gas liquors. C. SCHÖNBURG. *Brennstoff-Chem.* **12**, 69–71(1931); cf. *Glückauf* **64**, 836(1928).—The disadvantages of dephenolizing with C_6H_6 are discussed. *Tricresyl phosphate* has been found to absorb 10–20 times more phenols and also has the advantages of non volatility, insolv. in, and greater sp. gr. than, the liquors. Partition coeffs. for both are shown diagrammatically for phenol and cresol solns. and gas liquor. The phenols, after absorption, are driven off from the high-boiling tricresyl phosphate by heat or steam distn. under vacuum. Practice shows that only 4–5 parts of tricresyl phosphate are needed to dephenolize 100 parts of liquor contg. 3 g. phenol per l. and that a 6–8% phenol concn. so obtained in the phosphate requires only 5–6 parts steam per part phenol for complete recovery. Use for several months shows a selectivity for phenols and the non-soln. of tar. App., shown schematically, is described. F. W. JESSEN

Tests on a Birmingham (town gas-fired oven) furnace installation. C. M. WATER. *Gas J.* **190**, 576–7(1930).—Tests were carried out on a battery of 4 town gas fired oven furnaces to det. how far working efficiencies could be affected by the employment of special insulating material, improved recuperator elements, and in particular the precise control of primary and secondary air, and reduction of losses by leakage through doors and dampers. For a given operation of carburizing in the older type of furnace a fuel consumption of 16,000 cu. ft. of 500 B. t. u. gas was required. The improved installation used 6230 cu. ft. of gas of slightly lower calorific value. F. H. B.

A new commercial application of the Walter Feld polythionate process. FRITZ OVERDICK. *Z. angew. Chem.* **43**, 1048–51(1930).—To remove NH_3 and S from coal gas the following reactions have been used: $(NH_4)_2S_4O_6 + 2NH_3 + H_2S \longrightarrow 2(NH_4)_2SO + S$; $(NH_4)_2S_4O_6 + 2NH_3 + H_2O \longrightarrow (NH_4)_2S_2O_3 + (NH_4)_2SO_4 + S$, $(NH_4)_2S_4O_6 + 3H_2S \longrightarrow (NH_4)_2S_2O_3 + 5S + 3H_2O$; $(NH_4)_2S_4O_6$ (hot) $\longrightarrow (NH_4)_2SO_4 + SO_2 + 2S$, or $(NH_4)_2S_4O_6 + 2(NH_4)_2S_2O_3 \longrightarrow 3(NH_4)_2SO_4 + 5S$. The S is burned to SO_2 for re-use. Funke (*Gas u. Wasserfach.* **68**, 388(1925)) and Raschig (*C. A.* **15**, 940) have investigated the process. A modification at Leverkusen makes possible complete

removal of NH_3 and H_2S without addn. of foreign NH_3 if excess H_2S is present, by gas washing in several stages. H_2S alone reacts very slowly with $(NH_4)_2S_4O_6$, but rapidly when NH_3 is also present. Absorption of excess H_2S (without NH_3) is done in the first stage, where H_2S is concd., while in later stages the more difficult absorption of dil. H_2S is accomplished by the aid of NH_3 by the first reaction given. E. M. SYMMES

A new modification of the Feld polythionate process. D. SIAVORINUS. *Het Gas* **51**, 19–20(1931).—A short review of a new modification of the Feld process as developed by the I. G. and used at the mine Auguste Viktoria (cf. Overdick, preceding abstract). It consists of cooling the crude gas from the ovens to 25°, thus removing tar and part of the NH_3, and then removing both H_2S and NH_3 in 4 scrubbers by polythionate liquor circulating in the same direction as the gas. In the first scrubber H_2S is taken out to an extent of more than the equiv. of NH_3 present; in the second scrubber no NH_3 is present, but thionate and H_2S react to give free S. Furthermore, the regenerated liquor (treated with SO_2) contg. some free SO_2 is circulated over this scrubber. In the third scrubber is used a mixt. of thionate liquor with the NH_3 distd. off the primary cooler condensate; the gas is thereby freed of its last traces of H_2S. A final washing for removal of the remaining NH_3 is carried out in the fourth scrubber run on NH_3-free thionate liquor, which is subsequently used in the first scrubber. The spent liquor is worked up in the customary way: S is filtered off and the liquor decomposed at 120–30° to give a strong $(NH_4)_2SO_4$ soln., which is freed of thiocyanate by fractional crystn. The present process is an improvement over the former ones in that H_2S comes in contact with liquors of high NH_3 content. This has been found necessary for complete H_2S absorption. The thiosulfate formed from the tetrathionate of the active soln. during the reaction with NH_3 and H_2S is regenerated by the action of SO_2-contg. gases in a separate little scrubber. B. J. C. VAN DER HOEVEN

The storage of carbon monoxide. OTTO HEINRICH WAGNER. *Brennstoff-Chem.* **12**, 87–9(1931). In view of the possible use of CO as a motor fuel, three methods of storage have been investigated: using (1) liquid absorbent, (2) solid absorbent and (3) a reversible chem. combination. Ether-pentane mixts. were the best of the liquids (absorption increasing with decreasing b. p.), but liquid CO_2 and NH_3 showed no absorptive properties. Of the solids, activated C when packed in cylinders showed only 40% capacity increase over an unpacked cylinder at 40 atm., and less at higher pressures. Silica gel and chabasite showed a decrease in capacity at pressures under 100 atm. Solns. of ammoniacal and acid cuprous salts involved heating to deliver the absorbed CO and were corrosive. With solid cuprous halides, addn. compds. of the type $Cu_2X_2.2CO$ were formed very slowly during the first absorption but rapidly after a single removal of the absorbed CO. The addn. is quant., reversible and traces of H_2O greatly increase its speed. Purification as well as storage is thus feasible. The vapor pressures of the $COCl_2$ and $COBr_2$ showed 235 mm. Hg for the former at 20° and 1.67 atm. for the latter. A 40-l. cylinder holding 7 kg. CO at 150 atm. will contain 28 kg. when filled with 100 kg. solid Cu_2Cl_2. Warming to 50° then releases the CO for use, the vapor pressure of the addn. compd. being 5 atm. at this temp. Because of the cost of Cu_2Cl_2 the halides and ammoniates of Fe, Ni and Co as well as ZnO and CaO are being studied. F. W. J.

Ammonia synthesis by the low-pressure Mont Cenis process. W. F. SCHOLVIEN. *Chem. Met. Eng.* **38**, 82–6(1931).—The Scholven, Germany, plant is described. Coke-oven gas is the source of H. CO is removed from the gas by washing with liquid N. Conversion is effected at 400° and 100 atm. Economic data and advantages of the process are given. L. W. T. CUMMINGS

Development and inventions in tar distillation. ERNST WEISE. *Asphalt u. Teer* **30**, 1124–7, 1147–9, 1169–70, 1232–5, 1287–92, 1312–5(1930); cf. *C. A.* **24**, 3886.—This is a detailed digest of 106 recent patents. K. H. ENGEL

Specifications for coal tar in Holland. F. J. NELLENSTEIJN. *Asphalt u. Teer* **30**, 952–3(1930). K. H. ENGEL

Analysis of coal-tar-asphalt mixtures. H. MALLISON. *Asphalt u. Teer* **30**, 183–4 (1930). Sepn. of the components by sulfonation methods is not entirely trustworthy. The asphalt is converted into sol. and insol. sulfonic acids. Certain asphalts, sulfonated by themselves, showed slight increases in wt. When sulfonated in mixts. with 85% tar, they were changed, almost quantitatively, into sol. products. K. H. ENGEL

Thermal decomposition of coal-tar constituents. VII. Reaction products of the thermal decomposition of *m*-cresol. YOSABURO KOSAKA. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding No. 1, 10–2(1931); cf. *C. A.* **24**, 1958.—Pure *m* cresol was decompd. at 700°, 800° and 900°, as was done with C_6H_6 (*J. Soc. Chem. Ind., Japan* **31A**, 507; **31B**, 126(1928)) except that at 900° no packing material was used because of C deposits formed. Fractions of the distillate up to 120° were mainly C_6H_6 and PhMe. Fractions

above 120° were treated with NaOH soln. to sep. acid constituents; the remainder was sepd. into picrate-forming and non-picrate-forming substances. The former were mostly naphthalene, anthracene, phenanthrene and derivs., the latter mostly Ph_2, Ph_2O and derivs. Differences in packing material have little effect. The yield of C_6H_6, PhMe and PhOH is a max. at about 800°; the yield of naphthalene and anthracene varies little with temp., but the Ph_2 yield increases with decompn. temp. **VIII. Reaction products of thermal decomposition of *o*-cresol and *p*-cresol.** *Ibid* 12–3.—Pure *o*-cresol and *p*-cresol were decompd. at 800° and the products compared with those from *m*-cresol treated similarly. The main products were C_6H_6, PhMe, PhOH, naphthalene, anthracene, phenanthrene, Ph_2, Ph_2O and their derivs. Nearly 24% of *m*-cresol, 12% of *o*-cresol and 8% of *p*-cresol remain undecompd. The PhOH yield is 19% with *o*-cresol and *p*-cresol, but 4.6% with *m*-cresol. *m*-Cresol gives the most C_6H_6 and PhMe while *o*-cresol gives the most naphthalene and anthracene. **IX. Qualitative consideration of the reaction mechanism of the thermal decomposition of cresols.** *Ibid* 13–4.—The thermal activity of cresols has been considered previously (Fischer, *Abh. d. Kohle* 6, 172(1923); Hagemann, *Braunkohle* 28, 1095(1929)). A series of reactions based on exptl. data is proposed. The difference in nature of decompn. of the 3 cresols seems to be due to the relative stability of OH and CH_3 groups, CH_3 being more stable than OH in *m*-cresol, and vice versa in *o*- and *p*-cresol. E. M. Symmes

Light oil from water-gas tar. N. A. Orlov. *Zhur. Prikladnoi Khim.* 3, 585–7 (1930).—Light oil obtained in the manuf. of water gas which had a brownish color and d_0^{10} 0.9240 was distd. and the 141–50° fraction was taken to sep. styrene. This fraction, which had d_0^{20} 0.8794 and n_0^{20} 1.5121, on being treated with Br in chloroform soln, indicated the presence of about 30% of styrene. The bromination was carried out at 0° and the remaining hydrocarbons were distd. off with steam; the dibromide was twice recrystd. from alc. and m. 71 1.5°. In a vacuum distn. at 26 mm pressure the whole of the dibromide distd over at 150 2° and required only one recrystn. The light oil contains about 1.5 2% styrene. This method, however, is not recommended because other products present are also brominated. The pure styrene was obtained from the dibromide by the action of Mg. Attempts to obtain styrene without the use of Br by heating the fraction in an autoclave for 5 hrs. at 200° failed. Indene was easily sepd from the 176–85° fraction by the Weissgerber method (cf. *C. A.* 3, 1152) with a yield of 42 or 4.7% corresponding to that from the original light oil. The indene content is probably higher because the liquid becomes very hot during the reaction and polymerization can be noticed. A. A. Borhtlingk

Tar dehydration. Ehlert. *Gas u. Wasserfach* 74, 40(1931).—The longest possible tar well is desirable. Heating coils were so placed as to minimize mixing by convection. A week before tar was to be loaded, it was heated in about 24 hrs. to 50° and then allowed to stand without further heating for 5 days before loading. R. W. Ryan

Functions of coke ovens. Edward G. Stewart. Inst. Gas Eng., *Communication* No. 6, 30 pp.(1930).—See *C. A.* 24, 5136. G. G

Production, properties and use of coke. D. Aufhäuser. *Montan. Rundschau* 22, 521–4(1930).—Some statistics are given on the production of gas, coke and coal tar products in Germany. For gas making the C content of the coke should be high and the H content low. The size of lumps recommended is 2–9 cm diam. (0.75–3.5 in.), depending on the size retort used. Channing Wilson

Present position of the metallurgical coke industry in Central Europe. Cu Berthelot. *Rev. métal.* 27, 486–500(1930).—The present tendency in the Central European metallurgical coke industry is to improve furnace design and furnace equipment, and to analyze more intensively factors entering into the net cost of coke manuf. C. H. Lorig

The reactivity of metallurgical coke. Dufraine. *Rev. métal.* 27, 509–11(1930); cf. *C. A.* 24, 5980.—The surface of coke was modified by applying solns. of CaO and flux. The reactivity of 3 cokes to which 3 solns. were applied was detd. for 800°, 900°, 1000° and 1100°. Lime solns. decrease the reactivity of coke, thereby raising the CO_2 content of the combustion gases. C. H. Lorig

The determination of coke strength. Fritz G. Hoffmann. *Brennstoff-Chem.* 12, 61–5(1931); cf. *C. A.* 24, 5981.—The effects of fissuring, cooling or quenching strain and coke hardness upon the accuracy of the results obtained in tumbler, compression and shatter tests are discussed in detail. Causes of fissures in coke from various types of ovens, as well as in the carbonizing of briquetted coal, are studied. The use of an automatic screening, weighing and recording device is suggested for continuous detns. on a small part of the oven output. The tumbler with attached double screen is recom-

mended as the best-suited hardness test. The importance of testing carefully screened coke and the preferability of hand- to fork-picked samples is stressed. F. W. JUNG

Low-temperature pressed coke. E. ROSER. *Brennstoff-Chem.* **12**, 86–7(1931).—By using thin-walled, slightly tapered alloy steel cylinders of 300 mm. mid-diameter and 2800 mm. height, fitting in pairs into 400-mm. Otto ovens, a series of carbonizations at oven temps. of 750° has been made. A strongly swelling slack of 18% volatile carbonaceous matter (V. C. M.) and 5.4% ash was coked 4 hrs. A coking slack of 22.1% V. C. M. and 5.1% ash, and a 1:1 mixt. by vol. of this slack and an anthracite fine of 10.5% V. C. M. and 7% ash were coked 5 hrs. In each case a hard, large-sized and uniform coke resulted. Gas and tar yields were not detd. Analytical data are given for the coke obtained. Consumption and production data for light oil products in Germany are given in support of a low-temperature process. F. W. JUNG

Dry quenching of coke. WM. O. RENKIN. *Fuels and Steam Power* (*A. E. S. M. Trans.*) **53**, 65–85(1931).—See *C. A.* **25**, 1059. G. G.

The reductivity of over-crusted coke (PIWOWARSKY) **9.** Ammonia liquor as a fertilizer (BIMCHAS) **15.** The microbiological aspect of peat formation (THAYSEN) **8.** The present nature of coals resulting from their history (DUBRUL) **8.** The dehydrating action of coal ash (TANAKA) **18.** Separation and synthetic preparation of phenol (MIZOSHITA) **10.** Apparatus for eliminating CO from motor-vehicle exhaust gases (U. S. 1,791,912) **1.** Separation of tars, tar oils, etc. (Brit. pat. 336,945) **22.** Purifying light oils recovered from coal gas, etc. (Brit. pat. 336,636) **22.** Clarifying plant for coal industry (Ger. pat. 516,454) **1.** H and CO from CH_4, etc. (Brit. pat. 336,635) **18.** Separation of dust from gases (Brit. pat. 336,201) **13.** Purifying light hydrocarbons produced by destructive hydrogenation of coal (Brit. pat. 335,885) **22.** Purification of gases, etc. (Belg. pat. 371,622) **4.**

Fuel. WILHELM CLEMENS. Ger. 513,512, July 1, 1926. Dried pressed peat is pulverized, kneaded into a plastic condition with added substances and finally pressed into molds. The pulverized mass may be coked. App. is described.

Fuel briquets. SOC. ANON. LA CARBONITE. Ger. 513,731, May 6, 1924. Briquets of high calorific value, suitable for driving gas producers, etc., are obtained by distg. wood, peat or lignite below 500°, mixing the residue with oxidized tar below 500° and pressing. Cf. *C. A.* **24**, 1960.

Fuel for motors. N. V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 694,053, Apr. 16, 1930. Fuel suitable for motors is obtained by heating carbonaceous materials such as petroleum, asphalts, etc., in the presence of a compd. of Mo acting as a catalyst and in the presence of H under pressure, the conditions being chosen so that no splitting of the mols. of the treated materials takes place with formation of gaseous or low b. p. products. Examples are given.

Fuel for internal-combustion engines. JOHANN W. MICHEEL. Ger. 515,816, Nov. 26, 1929. Addn. to 515,076 (*C. A.* **25**, 1660). Soot is mixed with powd. fuels giving a relatively large amt. of ash, *e. g.*, lignite, wood charcoal or cellulose.

Vaporizing heavy fuels for internal-combustion engines. RECTOR GASIFIER CO. Brit. 336,243, July 9, 1929. The fuel is heated, sprayed radially to a common center from several orifices and an inert gas is passed at right angles through the sheet of spray thus formed.

Catalytic heating device for fuel of internal-combustion engines. OSCAR H. WALLIN. U. S. 1,792,337, Feb. 10. Various structural details are described.

Removing carbon deposits from internal-combustion engine cylinders. THOMAS & HOCHWALT LABORATORIES, INC. Brit. 335,963, June 5, 1929. A C-loosening compn. is used contg. a halogenated aromatic hydrocarbon (such as chloronaphthalenes, chlorobenzenes, bromobenzenes, halogenated toluenes or xylenes, benzal chloride or benzyl chloride, which may be dissolved in alcs., ether, acetone, EtOAc, kerosene, gasoline, C_6H_6 or the like) which is introduced into the hot cylinders. Examples with proportions are given.

Acetylene. CHARLES DE LA ROCHETTE. Ger. 513,692, Mar. 6, 1929. Details are given of a plant for producing an C_2H_2-air mixt. for motors and other combustion machines.

Solid acetylene. I. G. FARBENIND. A.-G. Fr. 694,001, April 15, 1930. C_2H_2 is stored and transported by cooling the gas to just below its m. p. and compressing the snow thus formed into cakes.

Wagon for the low-temperature distillation of bituminous fuels in tunnel ovens. N. V. MACHINERIEËN EN APPARATEN-FABRIEKEN. Ger. 516,153, Oct. 18, 1927.

Destructive hydrogenation. IMPERIAL CHEMICAL INDUSTRIES, LTD., R. HOLROYD and C. COCKRAM. Brit. 337,028, July 18, 1929. At the beginning of a multi-stage process for the destructive hydrogenation of bituminous coal, the coal is heated either *in vacuo* or in an inert gas or with H, with or without oil or catalysts, to a temp. at or just above that of initial thermal decompn. at which the ulmic constituents disintegrate. Preferably H is used under pressure in the presence of high-temp. tar or oils derived from a later stage of the process and in the presence of catalysts, and sufficient H is used to deoxygenate the coal and yield a fusible product. The material is then further hydrogenated and liquid products are fractionated from the resulting substances. Various details and examples are given.

Destructive hydrogenation. C. F. R. HARRISON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 336,991, July 19, 1929. Destructive hydrogenation under pressure is effected in a vertical tower in the presence of a massive metallic catalyst of large surface area such as plates, wire, ribbon or gauze. Various details of app. are described. Cf. *C. A.* **25**, 192.

Destructive hydrogenation of pastes of coal and oil. C. F. R. HARRISON, E. D. KAMM and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 336,610, July 16, 1929. Various details of app. and procedure are described for a process in which all the products from the reaction vessel pass through a common exit to a catch pot which is kept at such a temp. (suitably about 350°) that heavy oils are condensed while the vapors of middle and light oils are led away, and the heavy oils are returned to the reaction vessel.

Furnace and retort for drying, roasting or distilling solid materials such as coal. F. K. WOODROFFE. Brit. 336,657, July 18, 1929.

Coal. MAURICE DÉNOS. Fr. 694,979, May 5, 1930. The combustion properties of coal are improved by sprinkling it with water contg. soda, S, red ocher and CaC_2.

Apparatus for cleaning coal by air separation. ALWYN G. OPPY and GRANGER B. SADLER. U. S. 1,792,440, Feb. 10. Structural features.

Apparatus for cleaning and purifying coal. HARRY L. MCLEAN (one-third each to George W. Wilmot and Francis H. Blatch). U. S. 1,792,179, Feb. 10. Structural features.

Washer for coal, ores, etc. ANTOINE FRANCE. Ger. 516,145, Nov 21, 1926.

Liquid products from coal, etc. N. V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ Fr. 694,192, Apr. 18, 1930. Valuable liquid products are prepd. by treating coal, tar, petroleum products or residues, lignite or cellulose by heating under pressure in the presence of H and a catalyst composed of Mo compds. intimately mixed with finely divided absorbent substances such as absorptive charcoal.

Apparatus for determining the humidity of brown coal, etc. HANS TRAUTHWEIN Ger. 513,701, April 6, 1928. The water is evapd. in a closed chamber in a rotary drum app. and the condensate is measured.

Lignite cooling plant. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 513,860, Jan. 26, 1929. Addn. to 460,570. Cooling plates are arranged after the manner of venetian blinds.

Drying peat. WILHELM CLEMENS. Ger. 513,572, Jan. 25, 1927. To crude peat pressed peat is added, and the whole is further pressed and then treated with drying agents.

Montan wax. I. G. FARBENIND. A.-G. Brit. 335,929, July 1, 1929. Purification of montan wax is effected by extn. under pressure and at an elevated temp. (suitably 135° or 150°) with org. solvents of the wax acids and esters (but not of the coloring substances) such as aliphatic alcs., esters, ketones and ethers, open chain or cyclo-aliphatic liquid hydrocarbons or chlorinated hydrocarbons, alone or mixed or with a smaller quantity of aromatic hydrocarbons. Examples with details of procedure are given.

Removing phenols from ammonia liquor. GEWERKSCHAFT MATHIAS STINNES Ger. 517,001, Apr. 30, 1929. In removing phenols from ammonia liquor by means of a circulating org. solvent, the latter is desulfurized, before freeing it from phenols, by treatment with a suitable liquid or gas. Thus, the solvent may be washed with water, which may then be passed to the ammonia washer, or acrated to render it fit for use again. Alternatively, the solvent may be treated with coke-oven gases, which may traverse a cycle in which the H_2S taken up by the gases is removed by a solid purifying material or by an alk. wash. Cf. *C. A.* **25**, 801.

Gas purification. F. BÖNNEMANN. Brit. 336,425, Oct. 12, 1929. See Fr. 682,838 (*C. A.* **24**, 4616).

Gas purification. DAVID L. JACOBSON (to Koppers Co.). U. S. 1,792,097, Feb. 10 Gas is washed with an alk. suspension of a compd. of a metal of the Fe sub-group of the 8th group of the periodic system, such as Fe oxide, contg. in soln. a hydroxy deriv. of

an org. non-paraffin compd., such as 2% or less of a phenol, which retards formation of thio compds. Cf. *C. A.* **25**, 802.

Purifying gases. I. G. Farbenind. A.-G. Brit. 336,319, July 20, 1929. Coke-oven gases, low-temp. distn. gases, cracking gases and gases other than those mentioned in Brit. 329,688 (*C. A.* **24**, 5983) such as gases intended for the manuf. of synthetic NH_3, MeOH, etc., are freed from volatile S compds. such as H_2S and largely from CO_2 if present in appreciable proportion, by washing with high b. p. hydrocarbons or phenols or their mixts. under 10 atm. or higher pressure at such a temp. that the concn. of H_2S amounts to less than 0.3% by volume of the gas. The pressure is preferably released in stages. Various details and examples are given.

Purifying gases. Heinrich Koppers A.-G. and Christian J. Hansen. Ger. 513,953, Nov. 1, 1927. NH_3 and H_2S are removed from gases in the proportion of 2 : 1 by a washing liquid causing the formation of Fe, Mn or Zn thionate, and the excess of H_2S is removed by a second washing causing the formation of polythionates. H_2SO_3 is added to the second washing fluid. Cf. *C. A.* **24**, 1726.

Gases rich in olefins. I. G. Farbenind. A.-G. (Fritz Winkler, Paul Feiler and Carl Messerknecht, inventors). Ger. 513,845, Nov. 11, 1926. Gases rich in olefins are obtained by rapidly heating powd. bituminous coal to dull red heat and rapidly cooling the gas evolved. Superheated steam may be admitted to the glowing fuel. The examples describe the production of gas contg. 19 to 24% C_nH_{2n} from lignite by this method.

Heating and illuminating gas. Albert F. Kunberger (to United Gas Improvement Co.) U. S. 1,792,172, Feb. 10. A mass of coal is heated to incandescence with an admixt. of finely divided iron or Fe oxide in a chamber, and a mixt. of H and superheated steam is introduced into the heated mass, simultaneously addnl. coal is introduced into the chamber together with an admixt of a small proportion of finely divided Fe oxide, and the gases within the chamber are subjected for a time to steam pressure of 30–300 lbs. per sq. in. to cause the H to combine with the C to form hydrocarbon gases. App. is described.

Coal gas. Ges. für Linde's Eismaschinen A.-G. (Paul Schuftan, inventor). Ger. 513,815, Aug. 7, 1928. The small quantities of reactive gas remaining in coke-oven gas are removed, before splitting the gas by cooling to low temps., by passing it over an absorptive agent such as active C impregnated with metal or metallic salts, or over active SiO_2-gel. This removes the NO and traces of hydrocarbons remaining after the removal of the hydrocarbons, H_2S and water by the usual methods.

Washing coal gas. H. Koppers A.-G. Brit. 336,484, Sept. 27, 1929. In final water-cooling of coal distn. gases, the water, before re cooling, is washed or treated with tar to remove deposited naphthalene. App. is described.

Expansion machines for separating benzene from coal gas. Ges. für Linde's Eismaschinen A.-G (Paul Schuftan, inventor). Ger. 513,764, Sept 14, 1926. Addn. to 511,567 (*C. A.* **25**, 1265). Details are given for lubricating the machine by oil to which homologs of C_6H_6 or hydrated naphthalene are added to lower the congealing point. Glycol, ketones or monohydric alcs. may be added to the water-ice soln. to prevent excessive loss by evapn at low-vapor pressures.

Mixed oil gas and water gas. J. A. Perry (to Humphreys & Glasgow, Ltd.). Brit. 336,525, March 2, 1929. In the operation of a carbureted water-gas set, oil gas is obtained by passing sep. streams of a hydrocarbon fluid through the generator and through the carbureter, the hydrocarbon material being cracked by passage through the fuel bed, and the gas is withdrawn separately from that formed in the carbureter and superheater. Various details of app. and operation are described. Cf. *C. A.* **25**, 1063, 1662.

Water gas. Metallges. A.-G. and C. Mueller. Brit. 336,821, Nov. 4, 1929. Powd. and granular fuels are gasified by O in admixt. with steam, and part of the gas produced is reintroduced into the producer together with the gasifying medium, in which it is burned with a part of the O before the gasifying medium reacts with the fuel to be gasified.

Non-poisonous gas from blue water gas. W. H. Fulweiler (to Humphreys & Glasgow, Ltd.). Brit. 335,869, May 2, 1929. One portion of blue water gas is passed over a heated catalyst such as Ni and another portion is passed with steam over a heated catalyst such as activated Fe oxide to form chiefly H; the 2 gases are mixed, with removal of CO_2 and water vapor either before or after admixture. Some CO may remain.

Continuous water-gas production. J. Pintsch A.-G. Brit 336,965, July 22, 1929. In the continuous production of water gas by passing steam and water gas together with the fuel through a tube surrounded by a heating app. for the reacting

gases (as described in Brit. 295,717 (*C. A.* **23**, 2278)), the mixt. of previously produced water gas and steam is admitted progressively and cumulatively to the reaction tube at a number of points along the tube as well as through a space at the top of the tube. Details of app. are described.

Water-gas generator. W. B. CHAPMAN, C. W. ANDREWS and H. B. YOUNG (to H. A. Brassert & Co. and Western Gas Construction Co.). Brit. 335,203, Nov. 27, 1928. A generator is described having means for continuous ash removal, in the operation of which the air-steam ratio is such as to maintain a zone in which the ash is liquefied and a cooler zone below this in which the ash tends to solidify for removal by a mech. device.

Water-gas generator. H. G. TERZIAN (to Humphreys & Glasgow, Ltd.). Brit. 336,902, April 20, 1929. A generator using bituminous fuel has a perforated tubular gas off-take in the axis of the upper part of the generator and openings communicating with an annular chamber surrounding the carbonizing zone, and both blast and run gases pass through this annular chamber. Various auxiliary structural details also are described.

Combined water-gas and steam generator. CARL MARISCHKA. U. S. 1,792,178, Feb. 10. Structural features of an app. with a boiler chamber surrounding a generator shaft, a heating jacket surrounding the boiler chamber, and tubes disposed entirely within the heating chamber and connected at their ends with the boiler chamber.

Gas producer. J. A. MACDONALD. Brit. 336,932, July 29, 1929.

Gas producers. POETTER G. M. B. H. Fr. 694,116, April 17, 1930. See Ger. 503,750 (*C. A.* **24**, 5985).

Vertical gas producer. C. H. LANDER and T. F. HURLEY. Brit. 336,022, July 19, 1929.

Grateless gas-producer for the continuous gasification of coal dust or granules. JANOS KALICZKY. Austrian 120,427, July 15, 1930.

Gas producer and associated furnace and boiler. BABCOCK & WILCOX, LTD. Brit. 336,356, Aug. 22, 1929.

Charging apparatus for gas producers. A. L. GALUSHA. Brit. 337,005, July 23, 1929. Structural features.

Degasifying chamber for gas producer. CARL BLEYER. Ger. 510,351, Feb. 8, 1927.

Prevention of gummy deposits in gas mains, etc. W. H. FULWEILER (to Humphreys & Glasgow, Ltd.). Brit. 336,456, Dec. 17, 1928. Gum-forming constituents such as indene and styrene are left in the gas and the latter is treated with mono- or poly hydric derivs. of C_6H_6 or its homologs, as by spraying.

Tar distillation. GEORGE T. GAMBRILL, JR. (to The Barrett Co.). Can. 309,014, Mar. 3, 1931. A method and an app. for distg. tar are specified. The tar is heated without sepn. of the vapor; then the vapor is released and simultaneously the tar is blown with an inert gas preheated to a temp. approx. that of the tar; the vapor and inert gas are withdrawn, the mixt. is cooled to sep. condensible constituents, and the inert gas is heated and returned for further contact with addnl. portions of the tar. Cf. *C. A.* **25**, 803.

Coking coal. A. POTT. Brit. 335,910, April 27, 1929. A coking coal is first dried and heated externally to a temp. just below its decompn. temp. and is then transferred to another app. in which it is externally heated to effect distn. at a temp. not exceeding 550° (the second app. being preheated to about the temp. of the coal before introduction of the latter into it).

Wet or dry cooling plant for coke. C. OTTO & CO. G. M. B. H. Ger. 516,442, Aug. 3, 1926.

Coke ovens. RUDOLF WILHELM. Fr. 694,019, April 16, 1930. Construction of door is described.

Coke ovens with heat regeneration. ROBERT J. A. DE STORDEUR. Fr. 693,954, Dec. 14, 1929.

Coke oven for making semi-coke. SOC. GÉNÉRALE DE FOURS À COKE SYSTÈME LECOCQ. Brit. 336,809, Oct. 27, 1928. Structural features of app. with a vertical or inclined chamber oven lined with metal plates or partitions supported at a distance from the heated refractory walls and heated by radiation only (each metal chamber being enclosed on all its faces by the heating walls).

Multiple regenerative coke oven. C. OTTO & CO. G. M. B. H. Ger. 513,593, May 30, 1928. Details of arrangement.

Coke-oven construction and operation. K. BEUTHNER. Brit. 337,278, Jan. 3, 1929. Distillates are withdrawn from the bottom of the charge into a lower compartment forming part of a divided fuel support, whence they pass to an outlet pipe. Steam may be introduced for production of water gas. Cf. *C. A.* **24**, 2868.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

Artificial aging of mineral oils. III. F. EVERS AND R. SCHMIDT. *Wiss. Veröffentlich. Siemens-Konzern* **9**, No. 1, 357–68(1930); cf. *C. A.* **23**, 3565; **25**, 404.—The catalyst and procedure previously recommended for aging tests on mineral oils are used to show that the aging curve may be expressed by the equation $y = 2.3 \log x. C + K$, where $C = 10.1$ and $K = -11.3$. From the aging const. of a mineral oil, the sapon. value, acid value and tendency to polymerization during various stages in aging can be calcd., and a close approximation made of the av. life of the oil under elec. conditions. B. C. A.

Heat calculation for flash distillation [of petroleum hydrocarbons]. G. H. FANCHER. *Chem. Met. Eng.* **37**, 307–8(1930).—In calcg. the heat added during vaporization of hydrocarbons by means of Turner and Harrell's equation (*C. A.* **24**, 2280), more reliable results can be obtained by taking into consideration the av. sp. gr. and the temp. rather than the mol. wt. of the vapor formed. The value of the latent heat used in this calcn. should be obtained from the relation $l = (1/d)(110.9 - 0.09\,t)$, where l is the latent heat of vaporization in B. t. u. per lb., d the sp. gr. (at 60°F. compared to water at 60°F.) of the liquid vaporized and t is the temp. in °F.; this value is more accurate than that obtained from Hildebrand's or Trouton's rules. B. C. A.

Determination of carbon residue in petroleum products —Conradson carbon. B. ROSENBAUM. *Chem.-Ztg.* **55**, 106(1931).—Corrections are given for several Conradson C detns. previously reported (*C. A.* **25**, 804), with the explanation that the quality of these products has changed in the meantime. The possibility of a definite relation between Conradson C and viscosity is pointed out. D. F. BROWN

Ultrafiltration of petroleum. A. ZAHARIA AND E. LUCATU. *Bul. soc. chim. România* **12**, 90–4(1930).—In an attempt to settle the question as to whether paraffin, resins and asphalt are present in petroleum in colloidal or in true soln., petroleums of different types from 5 localities were subjected to ultrafiltration. Vulcanized rubber membranes of 0.04 mm. thickness and a vulcanization coeff. of 1.7 were used in the Brukner app. under a pressure of 150 atm. Two membranes were used that gave an effective filtration surface of 25 sq. cm. The resins of petroleum which are separable by 70% EtOH were found to be ultrafilterable All the paraffin in the petroleums used was ultrafilterable but the asphalt, both hard and soft, was removed quantitatively by ultrafiltration. This behavior indicates that the asphalt is colloidal but that the resins and paraffins are not. The asphalt retained by the ultrafilter was dissolved in C_6H_6 and cyclohexane and was again retained by the filter Several passages of an oil through the same filter removed the resins and left the pure dry asphalt, which dissolved readily in that portion of the petroleum that was ultrafiltered. This expt. shows that the asphalt exists in petroleum as a lyophile colloid. ODEN E. SHEPPARD

Contact filtration of bright stocks. V. MATUSEVICH. *Azerbaidzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 12, 64–75. A mixt. of long residuum from Dossor (85) and Makat (15) crude oil was treated with acid and in 2 stages with clay. Substitution of a NaOH wash for the 1st-stage clay treatment resulted in the formation of emulsions and in high ash content of the finished oil. Lab and plant results showed that long residuum requires 7–10% and cylinder stock 8–12% of 96–98% H_2SO_4, which is applied as a fine shower, with air agitation. Long residuum is best treated at 30–35° and cylinder stock at 45–55°, since at higher temps. the sludge discolors the oil. The time of contact is detd. by testing the oil on a glass plate and discontinuing agitation when large lumps of sludge begin to form (usually 20–45 min.). The main body of sludge is sepd. from the oil at once and the remainder is allowed to settle for 15–48 hrs. in settling tanks at not over 50–55° (heating even with steam coils is detrimental). Coagulation of the sludge with water, NaOH soln., clay, water glass, etc., fails to give good results. Operations are controlled by color tests (2% naphtha soln. of oil in a Dubosc colorimeter). Clay should be applied to acid oil but the oil should be free from sludge. With long residuum a mixt. of clay (10% by wt. of oil), pretreated with acid and water (1:3), is mixed with the oil and circulated through a Foster-Wheeler pipe still (construction and operating details are specified) and a mixing tank where the temp. should reach 165° (max. permissible temp. in pipe still is 170°). When the temp. reaches 90–100°, 5–10% more clay is added (total 15–25%). If all of the clay is added at the beginning, foaming is excessive. This clay treatment requires 6–8 hrs. but lab. results show that 40 min. contact gives the best color. The use of superheated steam shortens the time of treating

but the product is impaired. Loss of oil to clay is about 1:1 by wt. Similar results are obtained with cylinder stocks but more clay is required. Clay is sepd. from the oil on a filter press of the frame type; this is unsatisfactory because of loss of time. The following results were obtained in treating long residuum:

98% H_2SO_4, % by wt.	—	6	9	12	15
Color of acid oil, mm.	—	41	55	70	80
Sp. gr.	0.9182	0.9055	0.9046	0.9022	0.8997

V. KALICHEVSKY

Dielectric constants of petroleum and its products. V. ZHUZE. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 12, 88-98.—The dielec. consts. of petroleum and its products increase with the increase in sp. gr., b. p. and mol. wt. of oils. The same relation holds for paraffins, contrary to the conclusions of Pécheux (*C. A.* **21**, 169). The dielec. const. is very closely equal to $(n_D)^2$. For paraffins, the const. increases with the increase in m. p. The temp. coeff. of the const. is neg. for petroleum products. In abs. value it increases with the d. except for the paraffins, for which it shows a decrease. The temp. coeff. of paraffins is 2-3 times smaller than that of liquid mineral oils. The dielec. const. of naphthenic acids increases with increase in sp. gr., b. p., surface tension, index of refraction and mol. wt. V. KALICHEVSKY

Absolute viscosities of petroleum products from Groznui fields. L. SELSKIĬ AND E. SHCHEGLOVA. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 12, 130-1. V. KALICHEVSKY

Cold settling of surakhanui crude oil. A. VELIKOVSKIĬ AND S. NIFONTOVA. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 10, 109-11.—Satisfactory lab. results were obtained. V. KALICHEVSKY

Ligroin and gasoline content of straight-run and cracked distillates from Groznui crude oils. L. SELSKIĬ. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 12, 124-9. V. KALICHEVSKY

Many products from Burman crude oils. G. EGLOFF. *Oil and Gas J.* **29**, No. 30, 46, 133(1930).—The situation and production of the fields are discussed and the products obtained are described. J. R. STRONG

Analysis of petroleum and its distillates for reducible substances and adsorbable matter by means of the polarographic method with the dropping mercury cathode. B. GOSMAN AND J. HEYROVSKY. *Trans. Electrochem. Soc.* **59** (preprint) 23 pp.(1931), cf. *C. A.* **24**, 3419.—The electroanalytic method with the dropping Hg cathode and automatic polarographic recording of the current-voltage curves has been applied to the estn. of (1) electrolytically reducible substances and (2) adsorbable (surface-active) matter in petroleum and its distillates. The analysis of electroreducible substances is carried out by shaking the petroleum with a soln. of NH_4Cl and submitting the aq. ext. to polarographic examn. after the atm. O_2 has been expelled by H_2 or by the addn. of a sulfite. About 0.005% of reducible substances may be detected in this way. Many sorts of petroleum were found to contain acidic substances, probably *naphthenic acids*, which may be extd. by aq. alk. solns. and which possess a prominent anticatalytic action in the reaction between O_2 and sulfite. These anticatalysts suppress maxima occurring on current-voltage curves at pos. potentials, thus indicating their neg. charge and strong adsorbability. The content of adsorbable substances is detd. by adding the petroleum or its soln. in MeOH from a microburet to an acidified MeOH soln. of $CuSO_4$. The max. on the current-voltage curve, due to the latter soln., is hereby depressed and the diln. at which a half-suppression is reached is taken as characteristic for the adsorbability in the petroleum cut. *Naphtha* from different sources has been found to contain the least adsorbable substances (diln. no., 10-400), then gasoline (400-2000) and lubricating oil (3000-13,000). Crude oil is most adsorbable with diln. nos. up to 41,000. C. G. F.

Knocking and effect of antiknock compounds. J. LORENTZEN. *Z. angew. Chem.* **44**, 130-6(1931).—The causes of knocking were investigated in combustion expts. made in a cylindrical chamber with mixts. of air with pentane and hexane. Variations in the proportions of the mixts. showed that the reactions are different when knocking occurs and when it does not. Change of position of the spark in the chamber proved that knocking sets in when an incomplete combustion is propagated through the chamber and a pressure wave is reflected from the wall, causing an explosion of the partly oxidized products. The flame is propagated about twice as fast under knocking conditions as

otherwise. Turbulence increases the combustion velocity. In the exptl. arrangement used, knocking occurred in a turbulent gas mixt. only at pressures above 8 atms. The addn. to the fuel of antiknock compds., lead tetraethyl and iron carbonyl, had no effect. When the combustion products of the same antiknock agents were introduced into the combustion chamber previous to the ignition of the fuel, it was impossible to produce knocking below 5 atm. pressure, and when turbulence was produced at the same time, no knocking was observed, although the initial pressure was raised to 9 atm.

D. F. BROWN

Benzene and the evolution of ideas on motor fuels. BRUNSCHWIG. *J. usines gaz* **54**, 569-76(1930). Current theories on the causes and prevention of motor knock, the methods of refining fuel benzene, gum formation and the action of inhibitors, and methods of testing for gum-forming tendency are discussed. K. H. ENGEL

Knock rating of motor fuels. Note on experiments carried out in 1930. ANON. *J. Inst. Petroleum Tech.* **17**, 69-71(1931). From the results of a 2nd series of knock-rating tests participated in by the research labs. of the Anglo-American Oil Co., the Anglo-Persian Oil Co. and the Asiatic Petroleum Co., it was agreed that the bouncing pin was the best means of measuring knock intensity if the engine was small enough for it to function properly. The Sub-Comm. of the I. P. T. agreed upon the octane no. for expressing knock ratings in the future The results from the older types of testing engines can be compared with those from the Horning engine only by working out the correlation for each type of fuel separately. EMMA E. CRANDAL

Gases from crude oil cracked in the vapor phase. M. B. MARKOVICH AND V. V. PIGULEVSKII *Neftyanoe Khozyaĭstvo* **18**, 425-44(1930), cf *C. A.* **25**, 405.—Fuel oil was cracked in the vapor phase and the gas produced was sepd into 3 fractions, (*a*) permanent gas, (*b*) Blau gas, *i. e.*, liquid at 15° under 100 atm pressure and (*c*) light gasoline. These fractions contained, resp., in % by wt., H 2.4, 0.2, 0.0; satd. hydrocarbons 49.0, 29.6, 3.0, C_2H_4 25.2, 17.1, 0.0; C_3H_6 12, 24.3, 4.0; butylene 2.9, 9.0, 35.0, bivinyl 2.0, 6.6, 18.0; vapors of higher unsatd hydrocarbons 0.0, 2.5, 0.0; N_2, CO_2, O_2, etc., 3.0, 0.4, 0.0. The work was undertaken to det the possibility of using cracked gas in the manuf. of synthetic chem. compds. to replace natural fats, for prepg glycols, perfumes, etc. A. A. BOEHTLINGK

The vapor-pressure curves of motor spirits. P. MEYER. *J. Inst. Petroleum Tech.* **17**, 42-68(1931).—The Ramsay-Young boiling-point law, deduced from the Clausius-Clapeyron equation, may be expressed in the form: $\log P = K_1 - K_2(t/T)$. Vapor pressures of a large no. of air free motor spirits were detd., in Andrew's app., and by the methods of Rhodes and McConnell, Beistle and Prather, Tizard and Marshall and Bridgeman, Aldrich and White. All the results fell approx. upon the graph represented by B., A. and W.'s equation, in which the consts. of the Ramsay-Young equation are evaluated: $\log P = 6.76 - 3.88(t/T)$ Two methods were developed for calcg. the true hydrocarbon vapor pressure from the apparent vapor pressure to avoid the exptl. difficulty of removing dissolved air from a mixt. of volatile hydrocarbons. By the first method, the apparent vapor-pressure curve is regarded as made up of the true vapor-pressure curve plus an air-pressure curve. The 2nd method utilizes the apparent molal heat of vaporization for calcg. EMMA E. CRANDAL

Vapor-phase treatment of cracked gasolines in the Vickers cracking unit. B. P. FRADKIN AND D. A. STROM. *Neftyanoe Khozyaistvo* **18**, 445-8(1930).—Gasoline obtained in the Vickers cracking unit is evapd again and passed in the vapor phase through fuller's earth filters. The yield of the final gasoline amounts to 91.1%, while 0.2% of fuller's earth is consumed, based on 11 regenerations During this process the fuller's earth is continuously heated by flue gas, the temp. being kept at 230–5°. The untreated gasoline has a Stammer color of 3.2, gum 0.5%, no corrosive action, unsatisfactory doctor test, and a sp. gr. of 0.734. The treated gasoline has a color of 2.1, 0.3% of gum, satisfactory corrosion and doctor tests, and a sp. gr. of 0.737 A. A. BOEHTLINGK

Destructive hydrogenation in bomb-polymerization in cracking. S. A. KISS. *Ind. Eng. Chem.* **23**, 315-8(1931). The initial retardation of the decompn. in destructive hydrogenation, carried out in a closed bomb, is explained by the Poynting effect which abstracts the "activated molecules" from the liquid phase and transforms them into "non-activated molecules." Formulas are developed for the kerosene yield and the gas and gas-plus-gasoline yield, also for the amt. of polymerization. D. F. BROWN

Cracking unit of Jenkins. B. CHIRKIN. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 10, 67-92.—A complete description is given of the units bought from the Graver Co., including detailed drawings, dimensions, guarantees, etc. V. K.

Design of liquid phase cracking equipment. P. RYABUIKH. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 12, 76-82.—If the cracking rate doubles for every 10

the av. cracking rate (C_{av}) for the temp. interval $T_1 - T_2$ is $C_{av} = 14.5C_1/(T_2 - T_1)\cdot(1.074^{T_2-T_1} - 1)$, where C_1 = cracking rate at T_1. The length of the heating coil (L) is the sum of the length required to heat the oil (L_1) and the length necessary to supply the heat for cracking (L_2), calcd. as follows: $L_2 = L_1^2 q_b/q_a n\theta - L_1 q_b$, where q_a = cal. used in heating 1 g. of oil to the cracking temp.; q_b = cal. absorbed in cracking 1 g. of oil; n = the velocity of the oil in pipes in m./sec.; θ = heating time in sec. At temps. below 450°, L_2 is not over 2% and may be neglected but at 480° it may reach 25% of the total length. The temp. drop in the reaction chamber under adiabatic conditions is $T_2 - T_3 = q_b(1 - \alpha) + q_k/(1 + \beta)S$, where qk = heat lost to the surroundings; α = the fraction cracked before the oil reaches the chamber; β = the fraction recycled; S = the av. sp. heat of the oil between T_2 and T_3. For *isothermic* conditions $t_1 = T + QZ/GS_g(Z - 1)$; $t_2 = T + Q/GS_g(Z - 1)$, where t_1 = the temp. of the gases entering the heating coil; t_2 = the temp. of the gases leaving the heating coil; Q = the heat absorbed in the reaction chamber; G = the wt. of gases used per hr.; S_g = the sp. heat of gases; $Z = eQ/GS_g\delta_m$, where e = the base of the natural log. and δ_m = the temp. difference satisfying the relationship $\delta_m = Q/KH$, where K is the coeff. of heat transfer between hot gases and the oil, and H = the surface of heating coils. Sample calcns. are given. V. KALICHEVSKY

Heat balance in cracking reactions. V. KHOKHLOV AND P. MARKOSOV. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 12, 83-7.—The work of Ryabuikh (preceding abstr.) is criticized and a method recommended for calcg. cracking reactions is outlined. V. KALICHEVSKY

Present methods for investigating gasolines. N. KALANTAR. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 12, 55-63.—Various analytical methods are described V. KALICHEVSKY

Refining of cracked gasolines with clays from Surakhanui. E. GINZBURG AND A. MARKARYANTZ. *Azerbaĭdzhanskoe Neftyanoe Khozyaĭstvo* **1930**, No. 10, 93-8.—Clay alone gives unsatisfactory results but might be of value in combination with acid or hypochlorite. V. KALICHEVSKY

Perfect flexible method for treating [gasolines and naphthas]. C. O. WILLSON. *Oil and Gas J* **29**, No. 31, 38(1930).—A method has been perfected by the Union Oil Co of Calif. for economically treating all grades of gasoline and naphtha by a continuous acid treatment followed by contact with clay. This company also uses the heat from the recycle stock of their Cross stills to rerun the treated pressure distillate. J. R. STRONG

Determining gum contents of gasoline. OSCAR C. BRIDGEMAN AND ELIZABETH W ALDRICH. *Oil and Gas J.* **29**, No. 37, 42, 199, 200, 201(1931).—The Cu-dish method gave on the av. much higher results than either the use of a glass, silica or porcelain dish in an atmosphere of steam, or the air jet method with glass dish and air blowing on the surface of the liquid at the rate of 300 ml. per sec. On high-gum gasolines the glass-dish method gave higher figures than the air-jet, but for low-gum gasolines they are about the same. The values decreased rapidly from zero air flow to 300 ml. per sec and from there on did not change. Inert gases (CO_2 and N_2) gave somewhat higher results than those obtained with an atm. of air The methods thus far proposed have not been correlated with gum deposit in an engine. It is felt that a lab.-flow method can be devised that will simulate engine-manifold conditions and that can be used as a preliminary criterion for the choice of a method to be employed in the detn. of gum content This all seems to hinge on the true gum content; hence a method must be found to det the true gum content. J. R. STRONG

Determination of the gum content of cracked spirits. W. LITTLEJOHN, W. H THOMAS, AND H. B. THOMPSON. *J. Inst. Petroleum Tech.* **16**, No. 84, 684-95(1930).—This method of detg. gum, decided upon for tentative use in the laboratories of the Anglo-Persian Oil Co., is the outcome of a series of expts. in which the effects of varying many factors were tested. A 25-cc. sample of gasoline is evapd. in a hemispherical glass dish 7 cm. in diam., on a steam bath, with the aid of a jet of air at 0.5 in. pressure If the residue in the dish is not dry at the end of 1 hr. it is allowed to remain on the bath 15 min. after it is visually dry. Drying is continued in an oven at 150° for 1.5 hrs. If the gum exceeds 11 mg. in wt., a new detn. is made upon a sample just small enough to bring the quantity of gum under the 11-mg. limit. Results for vapor-phase cracked gasolines are more affected by the change from the old method of drying at 100° for 1 hr. than are those of gasolines formed by liquid-phase cracking. EMMA R. CRANDAL

Action of inorganic refining reagents on alkyl sulfides in naphtha. P. BORGSTROM AND J. C. MCINTIRE. *Ind. Eng. Chem.* **23**, 321-3(1931).—Expts. were run on the removal of alkyl sulfides dissolved in various samples of naphtha. The sulfides used were

ethyl, propyl, isopropyl, alkyl, butyl, isobutyl and sec-butyl sulfide. The reagents used were silica gel, mercuric acetate, mercuric chloride, solid mercurous nitrate, Zn sulfide, cupric sulfide, ferrous oxide, ferric oxide, cupric oxide, cobaltic oxide, Ni oxide, yellow mercuric oxide, Pb oxide, Al oxide, Zn oxide, chromic oxide, basic Cu carbonate, ferric nitrate, stannous chloride, Zn chloride and cupric chloride. The results show that the lower sulfides are more readily removed by mercuric acetate than the higher ones. The removal of the isobutyl and isoamyl sulfides was about the same as that of the normal compds. More sec-propyl and sec-butyl sulfides were removed than the corresponding normal compds. The action of mercuric chloride varied greatly. An appreciable difference was noted with mercurous nitrate according to the naphtha used. This reagent appears, however, to be the best available for the removal of alkyl sulfides.

Determining the congealing point of fuel oil. N. I. CHERNOZHUKOV AND A. M. GUTZAIT. *Izvestiya Teplotekh. Inst. (Trans. Thermo-Tech. Inst. Russia)* **1930,** No. 3, 33–5.—Put the fuel oil into a 200-cc. flask (about half full) provided with a thermometer, stir the oil at a rate of 80–100 revolutions per min. on a water bath which is 3–5° cooler than the congealing temp. of the fuel oil. When the oil reaches the bath temp. transfer it to a test tube provided with a thermometer which has been brought to the bath temp. Insert the test tube in a second tube, and place the assembly in a cooling bath, the temp. of which is kept 5° below that of the fuel oil. The congealing point is found by tilting the test tube at an angle of 45° at each degree.
A. A. BOEHTLINGK

Sapropelites from the river Barsas (Siberia). N. M. KARAVAYEV AND J. B. RAPOPORT. *Izvestiya Teplotekh. Inst. (Trans. Thermo-Tech. Inst. Russia)* **1930,** No. 3, 59–69.—Three types of deposits were found near the river Barsas: (1) dark-yellow, very dense, in layers, very difficult to grind; (2) dark gray, in layers, the layers becoming more distinct after drying; they can easily be sepd. and disintegrate into scales on grinding; (3) a piece of wood root with bark on it. These sapropelites contained moisture 1.2–3.5%, ash 16–29.8%, S 0.6–1.0% and volatile matter 60.5–80.6%. The elementary analysis of the combustible part gave: C 76–79.6%, H 7.3–9.6% and N 0.28–0.72%. The calorific value was 8150–9100 kg. cal. A low-temp. carbonization in a Fischer retort yielded 38.27–57.24% semicoke, 33.81–50.90% tar; water and the gas and loss amounted to 7.83–10.83%. The coke so obtained was dense and was good only as a low-grade com. fuel. The tar contained 2.35–3.84% phenols, 2.35–3.00% acids, 0.51–1.2% bases and 87.9–93.5% neutral components of 0.8437–0.8972 sp. gr. The tar distn. produced 16.7–25.4% b. below 200°, 35.9–43.6% b. below 275° and 56.4–64.1% residue b. above 275°. The gasoline fraction had a sp. gr. of 0.7608–0.7756 and an I no. of 136.7–142.3. It had an unstable color which, after treatment with H_2SO_4 of 1.84 sp. gr., washing with caustic soda and water and redistn., was stabilized, the loss through treatment amounting to 21.65%. The original gasoline fraction contained 21.50–24.3% of unsatd. compds. and 9.3–15.9% of aromatic compds. Its sp. gr. after treatment and redistn. was 0.7679. The kerosene fraction was also unstable in color. It contained 13–14.11% phenols, traces of bases, 85.89–87% of neutral components and had a sp. gr. of 0.817–0.8636. The gas-oil distillate was semi-solid (b. 280–350°) and contained up to 0.68% of paraffin, calcd. on the tar. In a destructive hydrogenation of 70 g. of the gas oil and 10 cc. of gasoline, with 2 g. of Al_2O_3 as catalyst, 67.5% of liquid product was obtained. The heating was continued for 4 hrs. at 415–25°. The original H pressure was 70 atm.; the final and max. pressures were 65–75 atm. and 200 atm., resp. An insignificant amt. of C and gas was formed. The liquid had 33.15% b. below 170°, 16.31% b. 170–230°, 14.29% b. 230–80° and 5.28% b. 280–350°; the residue was 18.06% and the loss 5.89%. Expts. carried out with Al_2O_3 and Al_2O_3 + CuO by heating the mixt. for 2–3.5 hrs. produced similar results. A destructive hydrogenation of the residue b. above 280° in the presence of Al_2O_3 and CuO yielded 33% b. below 175°, 13.25% b. 175–260°, 11.45% b. 260–80°, 14.37% b. 280–340° and 27.93% of residue (including loss). All fractions were unstable in color. Cracking of the 280–350° fraction at 405–50° for 1.5 to 2.25 hrs. at a pressure of 18–62 atm. yielded 51.85–77.7% of a product b. up to 280° and 22.3–32.45% of residue. The I value varied between

62.38 and 35.94. The gasoline and kerosene fractions, although off color, are suitable for com. purposes because they contain some aromatic compds. and unsatd. compds.
A. A. BOEHTLINGK

Oil-field waters of Alberta and Saskatchewan. W. P. CAMPBELL. *Trans. Can. Inst. Mining Met.* **32**, 316–32(1929).—The water problem in oil borings is discussed. A high chloride content generally indicates deep water; absence of chlorides and presence of sulfates and H carbonates indicate surface water. B. C. A.

The making of low pour point oils. E. R. LEDERER AND E. W. ZUBLIN. *Oil & Gas J.* **29**, No. 32, 64, 101(1930); cf. *C. A.* **25**, 1367.—There are 5 important methods for making an oil with low pour point: (1) solvent processes; (2) cold pressing; (3) cold settling; (4) centrifuging; and (5) Weir process. Solvent processes have attained little importance as yet because of the possible loss of solvent. These processes make an oil equal to the best com. products. Cold pressing is applicable to overhead oils only, and depends entirely upon crystn. of the wax into needles rather than plates. By careful control of the distn. and pressing in 2 stages it is possible to make an oil whose pour point is 0°. Cold settling consists in diluting the stock with about 70% of light naphtha, chilling and settling. The wax must be amorphous, not cryst. The viscosity of the oil must be sufficiently low to permit the wax to settle out. The oil must have a low sp. gr. for the highest possible gravity differential between soln and wax. Before centrifuging, the oil is slowly chilled, in soln. with 70% of light naphtha, at a rate of 5° per hr. to about —60°F. Truly cryst. wax cannot be sepd. by centrifuging. The Weir process consists in filtering cold with the aid of Hyflo-Super Cel One lb per gal. is added to the diluted oil, and the cooled mixt. is forced through a filter. The Hyflo Super Cel is abrasive and cannot be handled with pumps J. R. STRONG

Gasoline and lubricants by hydrogenation. R. T. HASLAM AND W. C. BAUER. *Oil and Gas J.* **29**, No. 37, 34, 165, 166(1931). —Hydrogenated oils are, in general, equal or superior to all others in the relationships that are the usual indications of quality. In the White motor, oil consumption was least for the hydrogenated oil and with the exception of one other oil the C deposit was lower. Tests in the Mack motor were more severe, but results were still favorable to the hydrogenated oil. The hydrogenated gasolines are very sensitive to addn. of tetraethyl lead, have low S and gum, and are equal to C_6H_6 for blending purposes. Hydrogenated gasolines are unlike most cracked gasolines in that the heavier fractions have the best antiknock qualities. J. R STRONG

Turbine oils. ANON. 5th All-Russian Thermo-Tech. Congress. *Izvestiya Teplotekh. Inst.* (*Trans. Thermo-Tech. Inst Russia*) 1930, No 1, 66 9.—Emba turbine oil distillate from the Konstantinovskii refinery after being used for 6 months in a turbine caused the bearing temp to rise up to 70°, a great amt. of sludge composed mostly of carbenes and asphaltenes being pptd. The same oil when overrefined became too viscous and the amt. of acid formed which was able to cause corrosion was quite appreciable. The same over-refined oil with water being admitted during the test run in a steam turbine produced, after 4 months' use, a great excess of sludge. Oil of the above type but slightly acidic and contg. an insignificant amt. of sludge changed very little in the presence of water, although it did not stand up in the de-emulsification test, the latter fact being explained by the formation of Cu and Fe soaps, while the same oil under normal conditions worked quite satisfactorily. A sample of Baku turbine oil was satisfactory under normal working conditions. To regenerate used turbine oils they may be centrifuged to sep. out water and sludge, while oils high in acid require refining. The lubricating system of the steam turbine should be blown out with steam to remove impurities. Considerable data concerning turbine oils before and after use are given
A. A. BOEHTLINGK

Make asphalt by vacuum reduction. D. H. BANCROFT. *Oil and Gas J.* **29**, No 36, 30(1931). —Asphalts of improved quality are being made in the El Dorado, Ark., plant of the Lion Oil Refining Co. by reducing the bottoms in a high vacuum. Heavy Smackover crude oil is processed through a combination dehydrator, topping unit and vacuum reducing tower. In addn., this unit makes a lubricating distillate, gas oil and gasoline. Asphalt can also be made from low-gravity Smackover fuel oil. The lower the abs. pressure the lower will be the ductility and the penetration. J. R. STRONG

Improving crude-oil asphalts. A. I. VORONOV AND N. I. LOGVINOV. *Neftyanoe Khozyaistvo* **18**, 449–60(1930).—Road asphalts meeting the various standard specifications were prepd. from paraffin-base, mixed-base and asphalt-base fuel oils by distg. the oils under high vacuum or with steam or refinery gas, followed by blowing with air. The oil sepd. in distn. was suitable for prepg. lubricating oils and cylinder stocks or it could be used for cracking. Careful distn. was required to avoid the conversion of tars

into asphaltenes, which increase the brittleness of asphalt. An extensive bibliography on asphalts is appended. A. A. BOEHTLINGK

Solubility of asphalts and pitches in various, less common, organic solvents. EMIL J. FISCHER. *Asphalt u. Teer* **30**, 1332-4(1930). - See *C. A.* **24**, 2589. K. H. ENGEL

The chemical nature of bitumen from Petchora. N. D. ZELINSKII. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, No. 14, 351-2. The bitumen is a black, viscous mass mixed with vegetable residues and possesses a rather sharp, characteristic odor. A sample was extd. with benzene. After the benzene was distd. off, the residue was distd. under vacuum (11 mm.). The distillate was a yellowish oily liquid which distd. under ordinary pressure without decompn. between 190° and 305°, and had the following compn.: C — 86.48% and H — 13.34%; d_{23} = 0.8590. The rather high d. indicates the predominance of heavy hydrocarbons of cyclic nature. The residue from the first distn. was distd. under high vacuum and the remaining mass was a hard tar of the following compn.: C — 85.00% and H — 10.64% This tar constitutes the main part of the Petchora bitumen. L. JACOVLEFF

Carbonization (of wood) in modern portable furnaces. ANTONIO BERNAD. *Instituto Forestal de Investigaciones y Experiencias* **2**, No. 5, 68-80(1929). - The disadvantages of the old method of wood carbonization (slowly burning open piles of wood) are such as to cause the gradual disappearance of this method. The use of portable metal furnaces improves the quality and yield of charcoal, eliminates the necessity of const. attention to the burning, prolongs the working season, prevents interruption by adverse weather conditions and supplies a source of power for running machinery. The details of construction and operating expenses are given. The Spanish woods used for the manuf. of charcoal are *Pinus sylvestris*, *P. halepensis* and *Eucalyptus globulus*. H. K. S

Purifying petroleum oils. KARL T. STEIK (to Standard Oil Development Co.). U. S. 1,791,941, Feb. 10. Oil is treated with a liquid mixt. of SO_2 and SO_3.

System for treating petroleum oils with reagents such as acid and adsorbent earths. SAMUEL J. DICKEY and ERNEST W. ROTH (to General Petroleum Corp. of Calif.). U. S. 1,792,003, Feb. 10. The oil under treatment is repeatedly and successively mixed with a mixt. of finally purified liquid and reagent sludge, the sludge is drawn from the mixts. formed, and successive treatments are effected with mixts. contg. successively higher percentages of unexhausted reagent. An arrangement of app. is described.

Desulfurizing petroleum oils. FRANCIS M. ROGERS (to The Standard Oil Co.). Can. 309,099, Mar. 3, 1931. Straight-run, low boiling petroleum distillates are desulfurized by passing the vapors through adsorbent clay maintained at a temp. around 650°F., whereby a substantial part of the combined S is disengaged as H_2S.

Distillation apparatus with entrainment separators for vacuum distillation of petroleum oils. ALEXANDER C. SPENCER (to Standard Oil Development Co.). U. S. 1,791,940, Feb. 10. The vapor stream from a vacuum still is cooled without substantial condensation. The direction of flow of the stream is then suddenly changed, its linear velocity decreased and the vapors are passed to a condensing zone. Various details of app., including an entrainment separator, are described.

Hydrocarbons. MELANIT A.-G. Fr. 694,682, April 29, 1930. Carbonaceous or hydrocarbon materials are converted to liquids of lower b. p. by prepg. a mixt. of the substance to be treated with a colloidal soln. of a metal such as colloidal Zn, and treating

the mixt. under pressure and heat, *e. g.*, by injecting it in the atomized state with the aid of H or gases contg. H into appropriate reaction vessels.

Purifying hydrocarbons. GENERAL TECHNICAL CO., LTD. Fr. 695,004, Aug. 2, 1929. Fractions of various hydrocarbons (petroleum, tars, etc.), particularly fractions of low b. p. (benzene, gasoline), are distd. by adding to the fraction a non-miscible liquid or a mixt. of non-miscible liquids, the b. p. of which is lower than that of the lightest sulfured compd. in the mixt. The mixt. is afterward distd. at the boiling temp. of the non-miscible liquid introduced so that the sulfured impurities are sepd. from the hydrocarbons and a distillate is obtained free from S. Water, alc., certain higher alcs. and ketones or halogen derivs. of hydrocarbons, alcs., aldehydes or ketones may be used.

Decolorizing and stabilizing hydrocarbon mixtures. I. G. FARBENIND. A.-G. (Walter Rosinsky and Karl Smeykal, inventors). Ger. 516,279, Aug. 17, 1928. The mixts. are treated with a small proportion of an aldehyde- or ketone-sulfoxylate at atm. or raised temp. An alc. may be added during the treatment, and afterward distd. off. Thus, crude lubricating oil may be treated with an equal amt. of MeOH and 1% of Na formaldehyde sulfoxylate and the alc. then removed.

Removal of naphthenic acids from hydrocarbon oils. FRANCIS M. ROGERS (to The Standard Oil Co.). Can. 309,100, Mar. 3, 1931. Naphthenic acids are removed from hydrocarbon oil by vaporizing the oil and passing the vapors upward through a tower, maintaining molten NaOH in the lower part of the tower and producing a small amt of reflux in the upper part of the tower to prevent entrainment of Na compds.

Hydrocarbon oil conversion. GUSTAV EGLOFF and JACQUE C. MORRELL (to Universal Oil Products Co.). U. S. 1,791,618, Feb. 10. After heating oil to a cracking temp. in a heating zone such as a coil of pipe in a furnace, vapors thus formed are subjected to dephlegmation and the dephlegmated vapors are subjected to catalytic treatment such as with Ni on pumice and the treated vapors are condensed and the distillate and uncondensed gases are collected, the uncondensed gases are scrubbed, passed through a desulfurizer and then admitted to a flowing stream of dephlegmated vapors prior to the subjection of the latter to the catalytic treatment. App. is described.

Hydrocarbon oil conversion. WM. R. HOWARD (to Universal Oil Products Co.). U. S. 1,791,622, Feb. 10. A body of oil is maintained at a cracking temp. under superatm. pressure in a zone of vapor evolution, vapors are taken off and subjected to a primary reflux condensation and the reflux condensate is returned to the zone of vapor evolution and there heated to the prevailing temp. but out of direct contact with the other material in such a zone (suitably by a reflux still within the main still) and vapors are evolved from the reflux condensate and these vapors are combined with the uncondensed vapors from the reflux condensation, and the combined vapors are subjected to secondary dephlegmation and condensation. App. is described.

Converting heavy hydrocarbon oils into lighter products. LESTER KIRSCHBRAUN (to Universal Oil Products Co.). U. S. 1,791,566, Feb. 10. A stream of oil is heated to a cracking temp. (suitably in a pipe coil in a furnace) and then transferred to a reaction zone, and the temp. imparted to the oil stream is controlled in accord with variations in the thermal condition of the oil stream as it is transferred to the enlarged reaction zone, to maintain it at a substantially uniform predetd. temp. App. is described.

Purifying light hydrocarbons produced by destructive hydrogenation of oil, coal, etc. R. SCOTT and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 335,885, May 31, 1929. Purification is effected by passing the material, while still in the vapor state and under a pressure of at least 10 atm., through a solid purifying agent such as bauxite or fuller's earth. App. and various details of procedure are described. Regeneration of the purifying material may be effected by treatment with air at 400–500°.

Purifying light oils recovered from coal gas, etc. J. A. SHAW (to Koppers Co.). Brit. 336,636, Nov. 6, 1928. Materials such as light oils recovered from coal gas and distillates from tar and petroleum are purified by washing with acid and then with an alk. soln. of Na phenolate in 2 stages, first in such quantity that most or just all of the acid present is neutralized and practically all the phenols liberated from the phenate dissolve in the oil, and second to effect neutralization and remove the phenols and any remaining acid. H_2SO_4 is usually employed. There are thus obtained from the first alkali washing solns. contg. practically no phenols, and from the second solns. of Na phenolates practically free from sulfates, sulfonates, etc., and these latter, with or without sepn. and recovery of the phenols, may be used for *purifying gas* or for *softening water*, etc.

Light hydrocarbon oil distillation and purification. D. A. HOWES, R. SCOTT and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 336,515, July 22, 1929. Kerosene and light hydrocarbons produced by destructive hydrogenation, cracking or straight distn.

are distd. at a suitable temp. below 300° in the presence of gaseous NH_3 and in the absence of inorg. acids, to improve color and restrict tendency to gum formation. Various examples are given.

Apparatus with superposed drums and heating flues for distilling hydrocarbon oils. JACKSON R. SCHONBERG (to Standard Oil Development Co.). U. S. 1,791,937, Feb. 10.

Cracking hydrocarbons. PAUL VEROLA. Fr. 694,495, July 31, 1929. In cracking hydrocarbons by heat treatment, the gases produced in the process are reintroduced partially or wholly into the liquids before, during or after the cracking thereof has taken place, whereby the properties of the residual oil are improved.

Cracking hydrocarbons. SOC. D'ÉTUDES ET RÉALISATION "ERÉAL" (SOC. ANON.). Fr. 694,744, Apr. 29, 1930. Gaseous products rich in hydrocarbons are decomposed to obtain valuable by-products by passing them through an incandescent mass. The speed of the current or the height of the layer traversed or both are regulated so that at the exit of the mass temps. are obtained which do not exceed that necessary for a product of good quality. The temp. of the mass is about 1000-1200° and of the exit gas 600–700°.

Cracking hydrocarbon oils. FRITZ HOFMANN and CARL WULFF. U. S. 1,791,562, Feb. 10. See Brit. 301,395 (*C. A.* **23**, 4059).

Cracking oils. I. G. FARBENIND. A.-G. Brit. 337,046, July 26, 1929. Metal compds. of 1,3-diketones sol. in hydrocarbon oils, such as the W, Mo, Cr, V, Mn, U, Nb, Zr, Ce, Sn, Ti, Al, Cu, Zn, Co or Ni compds. of acetyl-, propionyl-, and butyryl acetonates, are used, singly or in various mixts. with each other or with other suitable substances, as catalysts in converting into lower b. p. compds. materials such as mineral oils, tar oils or oils obtained by the destructive hydrogenation of carbonaceous materials. Various details and examples are given, and the process may be carried out at 300–600° with or without high pressure or use of H.

Cracking oils. A. P. SACHS (to Petroleum Conversion Corp.). Brit. 336,380, Oct. 6, 1928. In a cracking process in which the heat for the conversion is supplied by a heated carrier circulated cyclically, the H_2S which accumulates in the gas is washed from it by spraying the gas with water after it has been cooled to condense the vapors produced (and preferably after it has passed through the circulating blower). Various details of app. and procedure are described

Cracking mineral oils. S. SEELIG. Brit. 336,822, Nov. 7, 1928. See Fr. 684,456 (*C. A.* **24**, 5477).

Apparatus for cracking oil. GUSTAV EGLOFF and HARRY P. BENNER (to Universal Oil Products Co.). U. S. 1,791,617, Feb. 10. Oil is passed in a single passage through a pipe coil in which it is heated to a cracking temp., and a valve-controlled connection is provided for passing heated oil in liquid phase from the coil into either of the opposite extremities of an enlarged horizontal vapor chamber sepd. from the coil, and means, such as pipes of restricted diam., is provided for increasing the velocity of the oil as it reaches points near the entrances to the vapor chamber. The vapor chamber communicates with a condenser, and the app. is arranged for conducting the oil treatment under superatm. pressure. Cf. *C. A.* **24**, 4385.

Apparatus for distilling and cracking hydrocarbons. NIKOLAUS MAYER. Austrian 120,428, July 15, 1930. Addn. to 118,255 (*C. A.* **24**, 4927).

Oils. I. G. FARBENIND. A.-G. (Carl Wulff, inventor). Ger. 513,814, April 23, 1927. Aryl carbonates, formed by treating the phenols with $COCl_2$, are used as transformer and switch oils.

Refining mineral oils. RICHFIELD OIL CO. OF CALIFORNIA. Fr. 695,077, May 5, 1930. See U. S. 1,790,622 (*C. A.* **25**, 1374). Fr 695,078 describes a process for refining hydrocarbons by vaporizing them and bringing them into contact with a soln. of at least one metallic salt, *e. g.*, a salt of Zn.

Refining oils and waxes. COMPAGNIE PROVENÇALE DE RAFFINAGE DE CORPS GRAS MINÉRAUX. Fr. 694,469, July 27, 1929. Mineral oils and waxes are refined by dissolving them in naphthalene decahydride and treating with H_2SO_4 in the usual manner. The decahydride is afterward recovered by distn.

Atomizing heavy oils. KARL MODL. Austrian 120,725, Aug. 15, 1930. The atomization of heavy oils in a gas stream is facilitated by introducing a readily vaporized fuel into the gas stream. The method may be applied in connection with internal-combustion engines.

Fractional condensation of oil vapors. HARALD NIELSEN and BRYAN LAING. Ger. 513,613, Oct. 30, 1928. The vapors are passed through a rotary washer under which various fractions condense as the temp. falls. App. is described.

Condensing and separating apparatus suitable for use in steam distillation of

mineral oils. WM. W. HOLLAND (to Standard Oil Co. of Ind.). U. S. 1,792,164, Feb. 10. Structural features of a baffle and gravity sepn. app.

Decolorizing oils such as vapor-cracked gasoline or other mineral oil or distillate. N.-V. MIJN-BOUW-EN CULTUURMAATSCHAPPIJ BOETON. Brit. 335,952, Nov. 3, 1928. Decolorization is effected by solns. of alkali metal hydroxides in substantially water-free org. solvents miscible with the oil such as MeOH, EtOH, BuOH, glycerol or acetone, and small quantities of reducing agents such as Zn, Al, aldehydes or polyhydric phenols may be present. The alkali may be recovered by dissolving the still residue in water and calcining. Cf. *C. A.* **25**, 1374.

Refining gasoline. AUGUST P. BJERREGAARD. U. S. 1,791,521, Feb. 10. After removing water from gasoline, the dry gasoline is mixed with a high-test alc. and this mixt. is treated with dry caustic alkali.

Refining cracked benzine. OTTO ZECHETMAYR. Ger. 513,870, June 20, 1928. The benzine is led through layers of porous material contg. hydroxides of alkali or alk. earth metals. The layout is described

Use of mercury cyanide as an "antidetonant" with motor fuels. A. J. DUCAMP Brit. 335,828, Dec. 4, 1928. Several mixts. are described.

Separating paraffin from oil. ROBERT E. MANLEY (to Texas Co.). U. S. 1,792,234, Feb. 10. A wax-bearing lubricating oil stock is mixed with an added more volatile carrier oil such as a light asphalt-base lubricating oil which is less volatile than kerosene, and the carrier oil is then distd. off together with the paraffin wax under less than atm. pressure. An arrangement of app. is described.

White petrolatum. HUGH F. GALLAGHER (to Standard Oil Development Co.) U. S. 1,791,926, Feb. 10. A petrolatum-yielding material is treated with fuming H_2SO_4 in the presence of a heavy, normally liquid hydrocarbon material such as lubricating oil distillate to obtain a liquid product contg. suspended sludge, a readily-settling sludge such as asphaltic bottoms is added to this product so that the suspended sludge is pptd., and petrolatum is obtained from the residual reaction mixt. App. is described. Cf. *C. A.* **24**, 495.

Fractionating tars, oils, etc. J. KÁRPÁTI Brit. 336,945, June 18, 1929. See Fr. 691,360 (*C. A.* **25**, 1063).

Tank and distributing nozzle system, etc., for treating bottom settlings or cut oils with water, steam and soda ash. WM. YANTIS. U. S. 1,791,695, Feb. 10. Structural features.

Distilling bituminous materials. WERSCHEN-WEISSENFELSER BRAUNKOHLEN A.-G. Ger. 513,596, Oct. 6, 1928. Details are given of a vertical retort with an endless band or chain for circulating the bituminous material.

Treating bituminous sands, etc. KARL A. CLARK (to Governors of the University of Alberta). U. S. 1,791,797, Feb. 10. In sepg. bitumen from bituminous sand, silt or clay, the material is mixed with a reagent such as Na silicate giving an alk. reaction on hydrolysis, and the mixt. is introduced into a body of hot water to effect sepn. of the bitumen from the sand, silt or clay; a water-sol. inorg. compd. of a multivalent metal such as $CaCl_2$ is introduced into the hot water to coagulate the reagent and the silt or clay, and the bitumen is recovered from the surface of the water. App. is described

Continuous production of dispersions of thermoplastic material such as bitumens, gums and waxes. GEORGE A. BROWN (to Bennett, Inc.). U. S. 1,792,067, Feb. 10 Various details of app. and operation are described

Lubricating and insulating oils. I. G FARBENIND A.-G. (Mathias Pier and Ernst Hochschwender, inventors). Ger. 516,316, June 1, 1927 See Fr. 668,102 (*C. A.* **24**, 1499).

Lubricants. STANDARD OIL DEVELOPMENT CO. Fr. 694,225, April 19, 1930 Lubricants are obtained from a heavy hydrocarbon oil contg. impurities of a gummy or resinous nature by eliminating all the non-crystn. impurities from the oil, *e. g.*, by distn. and subsequent treatment with H_2SO_4, and treating the purified oil with a gas rich in H under pressure and at a temp. at which decompn. is relatively slow, *e. g.*, 371 426°

Reconditioning lubricants such as crank-case oil from internal-combustion engines. M. CZARNY and F. C. FROLANDER. Brit. 336,202, June 6, 1929. The lighter fluid impurities are absorbed by a wick and are evapd. from the wick in an app. which is described and which may be arranged to operate continuously in connection with an engine.

Apparatus for cleaning used oil by heating and filtering. FIRMA HERMANN BENSMANN. Ger. 516,183, Feb. 22, 1927.

Composition for removing carbon deposits and rust from internal-combustion engine cylinders or other surfaces. GEORGE R. WAGNER (one-half to Wm. L. Smith

U. S. 1,792,052, Feb. 10. Kerosene 1 gal., lubricating oil 1 qt., "lubricating graphite" 1.0–1.5 oz., ether 3 oz. and spirits of camphor 3 oz.

Turpentine oil, pine oil and rosin from coniferous woods. FRANCESCO C. PALAZZO. U. S. 1,792,392, Feb. 10. See Fr. 676,859 (*C. A.* **24**, 3110).

Turpentine. JEAN B. H. FONGA. Fr. 36,835, April 18, 1929. Addn. to 668,493 (*C. A.* **24**, 1737). Turpentine from maritime pine is treated with a solvent, the distn. temp. of which is below that of the turpentine, and the resinic acid normally present is pptd. by adding lime or other alk. earth base. The solvent is recovered and a turpentine of reduced acidity and absolute purity is obtained

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Construction of the crystalline part of cellulose. II. H. MARK AND K. H. MEYER. *Cellulosechemie* **11**, 91–100(1930); cf. *C. A.* **23**, 5077; **24**, 1500.—Cellulose interference to x-rays can be explained by a monoclinic structure; it leads to an atomic arrangement which is illustrated, and to micelles with a length of about 500 and width of about 50 A. U. The micelle surface reactions and the "permutoid" reaction are taken into account. According to the Hudon rule, the principal valence chain model makes possible the estn. of the rotatory power of various cellulose derivs. which is in agreement with practical knowledge. A method for x-ray comparison of cellulose prepns. is given and minor structural differences are discussed. C. A. BRAUTLECHT

Cellulose in the light of the x-rays. WM. BRAGG. *Cellulose* **1**, 80–3, 110–3 (1930).—See *C. A.* **24**, 2287, 5151. C. A. BRAUTLECHT

Structure of ramie cellulose as deduced from x-rays. O. L. SPONSLER AND W. H. DORE. *Cellulosechemie* **11**, 186–97(1930). On the basis of new exptl. evidence with x rays, S. and D. deduce a structural formula which appears to agree with known chem. and phys. characteristics. Three-dimension models, employed for comparison with location of atoms in the space lattice, showed the following characteristics: (1) The structure-forming units are arranged parallel and lengthwise in continuous chains. (2) The individual chains are arranged in rectangular order of dimensions 6.10 × 5.40 A. U. (3) Individual units in each chain repeat every 10.25 A. U. (4) One can assume individual cells to have the dimensions 6.10 × 5.40 × 10.25 A. U. (5) In the individual cell in every chain there are 2 C_6 units. (6) In the elementary cell the atoms are so arranged that a no. of planes appear whose space intervals have a simple numerical relationship to 10.25, namely, there are planes present which lie in intervals of 5.15, 3.40, 2.58, etc. It is concluded that the proposed mol. structure agrees with the x-ray analysis and apparently with all phys. and chem. characteristics; the cellulose structure is built up of glucose units; the amylene oxide ring formula agrees best with the x-ray findings; the glucose units are built up into endless chains through glucosidic condensation; combination between units is of a 1:1 and 4:4 type bridge; the 1:4 bridges which are characteristic of cellobiose do not exist in the structure of ramie cellulose; the chains are rectangular 6.10 × 5.40 A. U. separately arranged with the greatest length along the diagonal direction; a group of 8 glucose units is the simplest unit which the cellulose structure can represent, agreeing with the crystallographic unit with axes: a = 10.80, b = 12.20, c = 10.25 A. U.; the ramie fiber is a hollow cylinder in whose walls the crystallographic units are so arranged that the diagonal of the 6.10 × 5.40 space always takes a tangential position; the cellulose structure is stabilized, in length by primary valence forces which hold together the glucose units, transversely by the secondary valence forces of O atoms; the suggested structure permits the elasticity of the fiber in the direction of its length, explains in length and breadth, various coeffs. of elasticity and allows for computation of swelling phenomena; the structure indicates, in conformity with Irvine's methylation results, that the OH groups attached to the 2nd, 3rd and 6th C atoms are open for substitution. It is shown that ester formation is possible, without change of the fiber structure, only by spreading apart the longitudinal chains; the fiber structure can thus be weakened, and, if the introduced groups are large, the secondary valence forces can be sufficiently weakened so as to lose the ability to retain the fiber-like arrangement; since ramie cellulose is like other cellulose fibers it is probable that similar celluloses have a similar structure; the presence of xylose units in several celluloses can be carried through to the accepted belief that oxidation of glucose units leads to gluconic acid, which on subsequent decarboxylization yields xylose; and, that these changes would not appreciably change the suggested arrangement of the original fiber structure. C. A. BRAUTLECHT

Acetolysis of bamboo cellulose. S. OGURI AND M. NARA. *Chem. News* **142**, 184–5 (1931).—See *C. A.* **25**, 1072. G. G.

Bamboo. II. Bamboo lignin. K. SISIDO. *Cellulose Ind.* (Tokyo) **6**, 167–70 (1930); *Abstracts* 29–32 (in German); cf. *C. A.* **25**, 1669.—Bamboo is especially suitable for a study of lignin formation in vegetable material, because the shoots grow extraordinarily quickly. Shoots 5.8 m. long were divided into 3 parts, each part being then dried and pulverized, and the dry powder extd. exhaustively with alc.-C_6H_6 and dried *in vacuo*. Lignin was removed with 72% H_2SO_4, and its methoxyl no. detd. by the Zeisel method. The methoxyl nos. for the samples were also calcd. on the assumption that this no. represents lignin. Both calcd. and observed values show a decrease from the base to the tip of the shoots, but good agreement is not found. It is considered probable that in the samples more remote from the base of the shoot the whole of the methoxyl is not fixed to lignin, and it is concluded that the lignin is methylated gradually according to the growth of the bamboo, or combines with the residue which contains Me in order to give the higher values detd. Some properties of bamboo lignin have been compared with those of wood lignin, and it is found that they behave similarly. Thus C, H, ash and methoxyl contents are similar in amt. to those from spruce wood lignin. Also both spruce-wood and bamboo chips give a green coloration on immersion in concd. HCl, while, on sepn., the lignin gives a grayish violet coloration before, and a salmon-pink after washing with boiling water. This suggests that bamboo lignin also has a heterocyclic structure. The distribution of O in the lignin as hydroxyl, methoxyl, etc., is discussed. B. C. A.

Integral relationship of cellulose to difficultly soluble xylan in the structural substance of red beech (Fagus silvatica). I. E. SCHMIDT, K. MEINEL, K. NEVROS AND W. JANDEBEUR. *Cellulosechemie* **11**, 49–68 (1930).—Previous observations by Schmidt *et al.*, have shown that (*a*) dil. aq. ClO_2 affects lignin markedly and can be used to identify lignin or its fragments; (*b*) lignin does not undergo change with the carbohydrate part of the cell wall; (*c*) oxidation products of lignin which are insol. in water can be removed through salt formation with alkalin. salts such as Na_2CO_3, or action with H_2SO_3 in form of $NaHSO_3$, phenols or pyridine; (*d*) the unsatd. part of the cell wall (lignin) can be removed quantitatively; (*e*) the polysaccharides of the cell membranes are converted into water-sol. forms, especially *d*-galactose and carbohydrates which behave as derivs. of *d*-galactose such as *l*-arabinose, which differ from the carbohydrates of cell membranes that are built up from *d*-glucose and its conversion products such as *d*-mannose. Investigation of the skeleton substance of the wooded cell walls of cryptogams and phanerogams showed that COOH-contg. polysaccharides always participated in the building up of skeleton substance, a synthesis best explained by the ester theory. The above evidence led S., *et al.*, to investigate the quant. relationships of single polyose units of the skeleton substance and the manner of their combination. In red beech it was shown that the skeleton substance treated with 0.04 to 0.2% NaOH quant. to an easily sol. xylan, while ester-like combinations of acetyl groups are split off. The residue from the treatment with 0.04 to 0.2% NaOH is entirely acid-free and consists of cellulose and xylan. The skeleton substance contains two xylans, an easily sol. (I) and a difficultly or less sol. one (II). II can be sepd. from the acid-free mixt. of cellulose and I by soln. in 5% NaOH at ordinary temp. On the assumption that cleavage products of cellulose, such as result by 5% NaOH action, are dissolved simultaneously with xylan, there is a stoichiometrical relationship of one part xylose anhydride ($C_5H_8O_4$) in II to 3 glucose anhydride ($C_6H_{10}O_5$) in the cellulose. This observed regularity of skeleton substance in red beech is dependent upon the kind of after-treatment during the breaking up of the wood with ClO_2 when an excess of OH ions is prevented (which can be the cause of specific side reactions), also on age, standing, time of cutting, etc. It was found that the proportion of cellulose to II was 3 : 1 for red beech independent of age or geographical origin. Thus for the first time a marked mass-weight association is shown between two colloids. This leads to a view of the compn. of wood which apparently contradicts the incorporation theory based on a mixt. of cell membrane cellulose, pentosans, hexosans and lignin. Part I is devoted to the method of hydrolysis with ClO_2 and Na_2SO_3 with reference to improvements of the method. With p_H limits of 6.8–7.5, after ClO_2 treatment, lignin can be removed quant. by Na_2SO_3. Part II is devoted to the action of NaOH of different concns. (up to 17%) on the skeleton substance of red beech. With concd. alkali solns. the work was carried out under N. The carboxyl-contg. part of the skeleton substance is removed completely by 0.2% (0.05 *N*) NaOH. Polymeric carboxylic acid and polymeric xylose anhydride is extd., simultaneously with the hydrolysis of acetyl groups. The easily sol. I is sol. in 0.2% NaOH; the difficultly sol. II is attacked completely only by

5% NaOH. When 3% or 1% NaCl soln. is added to the alkali the plotted curve for % wt. loss against concn. of alkali takes a different course, being the same, however, for the 3 as for the 1% NaCl. Salts, other than NaCl, also affected the wt. loss. The const. wt. loss with 5–7% NaOH contg. NaCl, implies that concns. of 3% NaOH and upward cause soln. of II and part of the cellulose. Five % NaOH in presence of 3% NaCl seps. xylan quant. from cellulose. Thus from a mixt. of cellulose and (II), 5% NaOH contg. NaCl dissolves 21.39% xylan and leaves 78.61% cellulose, and upon dividing the % quantities by the equiv. wts., 132 for xylan and 162 for cellulose, the quotients 1:3 are obtained. C. A. BRAUTLECHT

Integral relationship of cellulose to difficultly soluble xylan in the structural substance of red beech [Fagus silvatica]. II. E SCHMIDT, W. JANDEBEUR AND K. MEINEL. *Cellulosechemie* **11**, 73–9(1930); cf. preceding abstract.—Red beech-wood meal treated with 0.25% ClO_2 in water oxidizes lignin, yielding products which can be removed by treatment with salt solns. having a p_H of 6.8. Na_2SO_3 serves to dissolve lignin (1) by yielding Na ions to form salt like sol. lignin derivs. and (2) by H_2SO_3 from Na_2SO_3 to form sol. products. At a p_H value of 6.8 (a higher p_H affects the polysaccharides) salts other than Na_2SO_3, such as Na_2CO_3, Na_3PO_4, or K xanthate can be employed under the same conditions of temp. (50–60°) leading to the same stoichiometrical relationship between cellulose and less sol. of the two xylans present. Repeated alternate treatments of SO_2, in form of 4% $NaHSO_3$ soln., and water-sol. phenols such as resorcinol, with ClO_2 completely removes lignin from the cell constituents. Polysaccharides are not attacked by this treatment and even after 400 hrs.' treatment with ClO_2, the ratio for delignified material of 3 mols. cellulose to 1 mol. less soluble xylan remains the same. C. A. BRAUTLECHT

The relation of the viscosity of cellulose ester solutions and temperature. III. E. BERL, H. UMSTÄTTER AND F. KARRER. *Z. physik. Chem.*, Abt. A, **152**, 284–94(1931); cf. *C. A.* **24**, 5151.—The previous equation is found to hold for nitrates or acetates of cellulose. The viscosity does not change after heating and cooling if no acid is present. The Berl-Büttler equation holds with sufficient accuracy for such viscose materials. An *improved app.* is described. V. F. HARRINGTON

Some remarks on acetylcellulose. FRITZ OHL. *Farbe u. Lack* **1931**, 51, 64.—A review. To test for the presence of cellulose sulfoacetate O. dyes the sample with a 1% aq. soln. of methylene blue. Particles contg. sulfoacetate are dyed a darker blue than acetate particles. G. G. SWARD

Changes in the viscosity of cellulose acetate-acetone solutions. C. G. RITTENHOUSE AND C. J. STAUD. *Paint, Oil & Chem. Rev.* **91**, No. 9, 9–10(1931).—The viscosity of cellulose acetate-acetone solns. increased faster than the concn., an indication of a colloidal system. G. G. SWARD

Chemistry of pectin and its relation to the formation of incrustations of cellulose. I. F. EHRLICH. *Cellulosechemie* **11**, 140–51(1930); cf. *C. A.* **24**, 65.—A summary of the chemistry of pectin, its general and com. phases and its discovery by Braconnot in 1825 to the present being considered. Much attention is devoted to pectic acids isolated from the com. pectins sepd. from beet-sugar waste and cull citrus fruits. Attention is also given to galacturonic acids, their isolation, relationships and characteristics. II. *Ibid* 161–70.—Enzymic transformations of pectin and possible formation of lignin from pectin are discussed. Cyclic tetragalacturonic acids *a* and *c* can be opened by pectin ferments, especially by *Pencillium glaucum* and Perisporiaceae; the latter are easily obtained from sugar-beet pulp. Taka-diastase acts on a partly neutralized soln. of galacturonic acids *a* or *c* at a p_H of 4–6 in the course of a day to yield tetragalacturonic acid *b*. The new Perisporiaceae enzyme named "pectolase" by E. is obtained in especially active form from exts. of old cultures of isolated Perisporiaceae molds, in dry form. With 5% pectolase, galacturonic acids *a* and *c* could be converted into galacturonic acid *b* in a few min. and this could be totally converted into cryst. *d*-galacturonic acid in 2 or 3 days. The behavior of enzymes on tetragalacturonic acids leads E. to regard them as original components of pectin. The enzymes from molds which have the most intense action on the middle lamellae also act most intensely in the hydrolysis of tetragalacturonic acids. E. suggests that the tetragalacturonic acids which have been previously obtained only by acid hydrolysis of pectin are also intermediate products of the original pectin mol. which have been degraded by enzymic action. The mechanism of the action of pectolase on pectin involves, under specific conditions, (1) the splitting off of MeOH, (2) the reaction of the liberated pectic acids with Ca salts to form an insol. Ca salt of galacturonic acid *a*, which seps. as a gelatinous coagulum. In studying metabolic changes in highly lignified plant parts, E. examd. flax in the same manner as sugar beets. In old flax pectin, because of a hydration, the tetragalacturonic

acid ring is opened so that the galacturonic acid mols. in the pectic acid are held together as members of an open chain. Very marked differences are shown by flax pectin as compared with other pectins, with regard to the alc. components of its hydratopectins. Whereas hydratopectins from beets, oranges, etc., yield 20–25% of araban contg. only arabinose, the fraction of flax hydratopectin sol. in 55–70% ethanol is a complicated hexopentosan mixt. of arabinose, xylose, galactose and fructose. On evapn. of the alc. soln. of this crude hexopentosan, 25% of a resinous substance resembling lignin is obtained. After washing with cold water, and repeated soln. in NaOH and pptn. with HCl, a dark-brown powder results which is insol. in water and acids but sol. in alkalies and NH_4OH and shows no trace of carbohydrate. Its reactions and analysis show that furan nuclei are an integral part of it. E. concludes that the original substances of lignin in plants are really pectins and that the substances isolated from partly lignified flax straw represent intermediate products in the change from pectin to lignin. This resin and the hexopentosan from sugar-free flax straw were firmly held to the parent substance, because prolonged extn. with 70% ethanol did not remove them. In comparing the lignin (resinous product above) with other lignin prepns. E. states that (*a*) wood contains practically no pectin, (*b*) the larger part of the lignin is found in the middle lamella of wood, analogous to the pectin of the new nourishing tissues of young plants, (*c*) it appears that the methoxyl and acetyl content is derived from pectin, (*d*) all kinds of pectins, in addn. to galactose, are characterized by a high content of pentoses or pentose-like groups such as arabinose, xylose and tetragalacturonic acids (which can be regarded as carboxyl pentosans) and (*e*) it is very probable that a conversion of pectin into lignin is caused by chem. and enzymic processes during growth and aging. The change can be represented by the equation: $C_{66}H_{88}O_{40} \longrightarrow C_{48}H_{48}O_{16} + CO_2 + 10H_2O + 6O_2$ C. A. Brautlecht

Viscose. XXXIV. Effect of chlorination on the properties of cellulose. S. Masuda and J. Murakami. *Cellulose Ind.* (Tokyo) **6**, 173–4(1930); *Abstracts* 33–4.—Previous work by the authors has shown that the properties of sulfite pulp are improved by chlorination of the material at 15°, and similar results are now found for cotton. The Cu no. of the purified cotton cellulose used was reduced from 5 to 4 as a result of chlorination for 15 min. at 24° and washing with water, under standard conditions, and to 3 by similar chlorination for 30 min. B. C. A.

Recent developments in the preparation of viscose and viscose silk. Hanns Schmidt. *Chem. Fabrik* **1931**, 73–7, 85–90, 97–100. A review of improved methods and machinery with suggestions of possible simplifications. German and foreign patents are cited and 52 literature references are given. J. H. Moore

The enzymes of barley malt. VI. Fermentative decomposition of viscose silks. H. Pringsheim and E. Thilo. *Cellulosechemie* **11**, 100–2(1930); cf. Otto, *C. A.* **23**, 4955.—On fermentation certain small specific hydrolytic differences were observed; also that there does not appear the slight hydrolysis of viscoses pptd. in the presence of strong salt concn. in comparison to viscoses coagulated with H_2SO_4 alone. Viscose silks pptd. with $(NH_4)_2SO_4$ and then fixed with dil. H_2SO_4 are least decompd. and differences in behavior with other enzymes are probably due to differences in absorptive properties of the surface layers of the viscose filaments. C. A. Brautlecht

New bark [and sap] of wood of spruce, pine and red beech. C. G. Schwalbe and K. E. Neumann. *Cellulosechemie* **11**, 113–28(1930).—Extns. of sugar-like substances, hydrolyses, detns. of pentosans, extn. of bark with $Ca(OH)_2$ and $Ba(OH)_2$, acid hydrolysis after swelling with NaOH soln. and detns. of resin-fat wax content were made. Wood forming saps were investigated. Bark can be easily removed in the spring because the cambium cells are very tender. In fall and winter, these cell walls are heavily incrusted and the bond between bark and wood is a strong one. Dil. acids dissolve the incrusted substances in spruce and pine. Similar treatment has no action on the beech. Hot-water extn. showed only negligible quantities of sugar in the bark of all 3 trees, indicating that sugars played no important part in the formation of the incrustation. Results of hydrolyses with dil. acids were different between the coniferous and deciduous barks. The conifers yielded more sugar from the inner bark than from sap wood, indicating the presence of easily hydrolyzable hemicelluloses in the barks of these trees. All representatives of hexosans, commonly found on wood hydrolysis

(except glucose), could be shown to be present, but no pentosans. The pentosans were therefore not attacked by the dil. acid. The bark contains more pentosans than the sap wood but the ratio is less than that of the hexosans. Since the bark-incrusting material is mostly hexosans, in coniferous woods, dil. acids effect a partial soln. of incrusting material and therefore a weakening of the bond between bark and sap wood. The supposed mother substances of the hemicelluloses, carbohydrates and pectin substances were detd., also the ether-sol. and substance volatile with steam, also ash and adsorbable tannins. In addn., the presence of important org. groups such as acids, alcs., aldehydes, phenols, etc., was tested for by pptn. and color tests. The total residues of all saps were small. The ash in residues was high because of the presence of appreciable quantities of org. salts. From the ash analysis of autumn wood and bark, especially from the Ca content, S. concludes that the mineral salts in the saps are stored in the bark, after the growing period. Substances adsorbed by hide powder were very high in pine and lowest in beech and yielded pos. tannin tests. Reducing sugar content of the saps was appreciable, being highest in the beech. These included hexoses, which were preformed in the sap. The content of total fermentable carbohydrates after hydrolysis was greatest in the beech. The pentose content of all the saps was remarkably small, but greatest in beech, although still small in ratio to hexoses. This suggests that the pentoses are derived from hexoses and that they are transformed in the same measure as produced. The ether exts. were chiefly resins. The fat and wax accumulation in the cambium layer of the beech in the autumn was not observed in the sap. Substances volatile with steam (ethereal oils, terpenes, etc.) were found only in small quantity in the saps, chiefly in pine. Oxalic, succinic and citric acids could be sepd. and identified in beech as well as in pine sap. Lactic acid could be found only in beech. Tartaric, malic and acetic acids could not be found. Oxalic, succinic and citric acids could have been formed by simultaneous oxidation and splitting of carbohydrates in the growing process. Lactic acid is probably due to fermentation of the sap subsequent to extn. The acids exist free, in part, and yield an acid reaction in the sap. Neither EtOH nor MeOH could be detected. Coniferyl alc. was found in pine sap. Vanillin was found in the 3 saps, and it is assumed that coniferyl alc. is converted, in part, by oxidases or enzymes, into vanillin. Aliphatic aldehydes were absent. Guaiacol was present in very small quantity. The aromatic substances, which were found, all belong to the protocatechuic group and may be intermediate products in formation of lignin, although the quantity is less than that of lignin in the finished wood, especially in the conifers. This is addnl. support for the view that lignin is derived from the hexoses present in excess over the intermediate products (pectin, pentoses, pyrocatechol derivs.). Proteins are present only in traces and are probably derived from the protoplasm of the living cambium cells. C. A. BRAUTLECHT

Apparent destruction of coniferous wood by larva of common beetle [Hylotrupes bajalus, L.]. R. FALCK. *Cellulosechemie* **11**, 89–91(1930).—In studies to det. the changes in wood substance caused by insects inhabiting wood, F. examd. fir wood attacked solely by this larva, dividing it into (1) the fine powder from the bore-hole and (2) the adjacent wood. The air-dry wood contained 9.6% water, the borings 9.4%. The borings which had passed through the food tube of the larva were of the same color and in other phys. characteristics was similar to the pulverized wood, except as to degree of pulverization. Ash, cellulose, lignin, fat, wax, resin, pentosans and hemicellulose were detd. in both the larva borings and sound wood powder. The lignin and resin contents were the same; total pentosan was practically the same; the larva borings contained 12.27% less cellulose. The hemicellulose from the larva borings contained 2.96% less glucose (equiv. to 2.67% less hexosan), 1.09% more pentosan in soln. and 0.76% less pentosan in the residue. H_2SO_4 (69%) at 10–12°, in a shaking machine for 2 days, removed 12.29% more cellulose and hemicellulose from sound wood powder than from larva borings. Conclusion: The larva of the common beetle removes about 21% cellulose and hemicellulose from the wood without changing the remainder. F. suggests that the lignocellulose complex, pre-existent in the original wood, is unaffected. C. A. BRAUTLECHT

Apparent destruction of wood by larva of Annobium [common wood worm]. R. FALCK. *Cellulosechemie* **11**, 128–9(1930); cf. preceding abstract.—Analysis of sound pine wood meal and of the finely disintegrated wood after digestion in *Annobium striatum* showed practically no difference between the 2 products as to fats and resins, alkali-sol. material, pentosans and lignin. The insect apparently consumes about 9% cellulose, and, since the lignin content is the same, it is probable that the cellulose consumed is loosely, or not at all, combined with lignin in the original wood. Of the hemicelluloses, a slight difference exists in the hexosan part, being 2.62% less in the worm

product (= 19% of the total hexosan fraction); the pentosans in the soln. are 0.53% higher, and in the residue 1.5% less. These results compared with those having to do with the common beetle are the same as to kind but differ in quantity. The analytical data lead to the conclusion that insects living in wood which do not yield a different colored residue utilize only a certain cellulose fraction, which is not combined with lignin or is only slightly combined. C. A. BRAUTLECHT

The visible digestion of wood for pulp. H. R. HAMMOND. *Chemist Analyst* **20**, No. 2, 17–8(1931).—A glass cylinder digester capable of withstanding 150 lbs. pressure is shown. W. T. H.

Some observations on digesting sulfate pulp. DAVID JOHANSSON. *Svensk Pappers Tid.* **33**, 916–28(1930).—Digesting in autoclave and testing the resulting pulp gave the following results: (1) The strength of the ground pulp increases with the increasing Roe Cl no., being max. at Cl no. 7. Ease of grinding decreases with increasing Cl no. (2) The max. removal of lignin occurs with a 25% Na_2S content. A lower Na_2S content raises the lignin content. The strength no. is lowest for soda pulp and highest for Na_2S pulp. (3) In spite of careful treatment and low final temp. during digesting it was impossible to make soda kraft pulp of the same strength as sulfate kraft pulp. Addn. of bleach liquor does not increase the strength. The lignin content is higher for soda pulp than for sulfate pulp for corresponding yields and appearance. (4) Shortening the chips down to 10 mm. does not affect the strength of the pulp. (5) Sulfate pulp from douglas fir, goblolly pine and southern yellow pine from the U. S. compared with sulfate pulp from Swedish pine and spruce showed that the Swedish pulp, in spite of its shorter fiber, gave a stronger paper. WILHELM SEGERBLOM

Determination of the bleaching of sulfite pulp by potassium permanganate. H. J. *Svensk Pappers Tid.* **33**, 928,31(1930).—In detg. the bleaching of sulfite pulp in the lab. by the Bjorkman no. method it was found that dry undefibered pulp gave varying results. It is necessary to defiber indirectly digested pulp before treating with $KMnO_4$. An improved method is described, involving dry pulp, defibering in H_2SO_4 soln., successive treatments with $KMnO_4$, $Fe(NH_4)_2(SO_4)_2.6H_2O$, H_2SO_4 and $KMnO_4$, and calcg. in percent of $CaOCl_2$ by a special curve. Exact data as to quantities, times and temp. are given. WILHELM SEGERBLOM

Uses of paper in electrical apparatus. W. H. ANDERSON. *Elec. J.* **28**, 99–103 (1931).—See *C. A.* **25**, 1080. W. H. BOYNTON

Protecting wallpaper from fungi (Brit. pat. 336,244) **18.**

Cellulose. HEINRICH KÖRBER. Austrian 120,351, Jan. 15, 1930. Cellulosic materials such as sulfite or soda cellulose are refined by treatment with hydrocarbons. The treatment may be effected in the hollander and the hydrocarbons may be used in the form of an aq. emulsion. Thus, unbleached cellulose in 15–20 times its wt. of water may be treated at 80° for 1 day with 10% of its wt. of hydrogenated naphthalene.

Cellulose. I. G. FARBENIND. A.-G. (Emil Hubert and Karl Weisbrod, inventors) Ger. 513,693, Oct. 11, 1927. Stable solns. of cellulose in $CuO\text{-}NH_3$ are obtained by adding catalyzers, especially CN compds., before or during the dissolving process to prevent deterioration of the soln. by the action of atm. O. The amt. of CN compd. added does not exceed 5%. Examples of CN compds. mentioned are $K_4FeC_6N_6$, KCN, HgC_2N_2 and $K_3FeC_6N_6$.

Bleached cellulose from materials such as wood. ERIK HAGGLUND. U. S. 1,792,009, Feb. 10. Raw material such as beech wood is partly decompd. by boiling with alkali and the partly decomposed material is then treated in aq. suspension with Cl for a time sufficient to impart a uniformly brown color to the material, and after this, decompn. is completed by addn. of hypochlorite, by which intermediary lower Cl-contg. acids are formed which change the color from brown to yellowish white; the material is then washed and subsequently further bleached with $Ca(OCl)_2$.

Saccharifying cellulose. COMMERCIAL ALCOHOL CO., LTD., J. S. ARTHUR and R. GOGARTEN. Brit. 337,017, April 20, 1929. Cellulosic material which has a low water content or which is dried down to about 10% moisture content or less is treated with steam until it has a moisture content of about 20–40%, treated with HCl gas under cooling until decompn. is effected, and then, without removing the HCl, further treated with steam or a mixt. of steam and inert gas to saccharify the decompn. products (the vessel preferably being heated to 60–70° during the saccharification). Various auxiliary treatments are described.

Cellulose saccharification. COMMERCIAL ALCOHOL CO., LTD., J. S. ARTHUR and R. GOGARTEN. Brit. 336,934, April 20, 1929. In the treatment of sawdust or other

cellulosic or closely related materials, the material is dried (suitably to a moisture content of about 10% or less) and is treated with steam and a volatile acid gas such as HCl or HF uniformly to distribute the acid and water throughout the material, and decompn. is then effected with the same acid under such conditions of low temp. (suitably —10° to —15°) that no substantial formation of sugar occurs. Saccharification is then effected without removing the acid by direct steam heating or by indirect heating to 50–100°, followed by de-acidification and conversion of the sugars to monoses by treatment with steam under pressure or by boiling with acidified water. Brit. 336,935 relates to a generally similar procedure in which, however, the starting material may contain up to 50% of moisture.

Treating cellulose. CAMILLE DREYFUS. Fr. 694,879, May 2, 1930. The properties of cellulosic materials are improved by treating them with alk. liquids at a temp. below atm., *e. g.*, a 10% NaOH soln. may be used at —10°. The product may be activated subsequently with AcOH or HCOOH with a view to esterification.

Molded products from cellulosic material. FREDERIC H. SMYSER (to General Elec. Co.). U. S. 1,792,254, Feb. 10. A cellulosic material such as sawdust, bagasse or cornstalks having natural substances capable of yielding resinous compds. is digested with NaOH, and H_2SO_4 is added to the digested mass to ppt. the dissolved resinous constituents, the material is filtered and the mass is washed until neutral, dried at about 80° and there is added to the dried mass about 5–40% of hydrated lime, the material is powdered and is molded under heat and pressure.

Cellulose derivative. SOC. LYONNAISE DE SOIE ARTIFICIELLE and PIERRE CHEVALET. Ger. 516,462, Dec. 23, 1926. A formylacetylcellulose is prepd. by treating cellulose at a low temp. with HCOOH in the presence of a small proportion of H_2SO_4, then kneading the mass with AcOH contg. more H_2SO_4, and finally pptg. the product with water or EtOH. An example is given.

Cellulose derivatives. LEON LILIENFELD. Ger. 516,461, May 20, 1924. See Brit. 231,809 (*C. A.* 19, 3592).

Cellulose derivatives. HENRY DREYFUS. Fr. 694,881, May 2, 1930. Weighted or mordanted materials of, or contg., cellulose esters or ethers are prepd. by incorporating a weighting or mordanting metallic radical, or an agent capable of pptg. this radical, with the spinning soln. used for making the materials. The metallic radical may be used in the form of a thiocyanate. Examples are given of the use of compds. of Sn and Fe.

Nitrocellulose. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,623, April 28, 1930. Nitrocellulose is prepd. by making, without disaggregation, a uniform cellulose having a high apparent d. and giving limpid solns., by systematic subdivision of pulp in the form of plates or sheets to obtain pieces or tablets practically uniform, and nitrating these uniform tablets with a mixt. of H_2SO_4 and HNO_3.

Alkali cellulose press. HANS HASELMANN. Ger. 513,863, May 8, 1927. Details of construction are given.

Cellulose esters. JOHANNES ALLES. Ger. 513,541, Mar. 29, 1928. Solns. and plastic masses of cellulose esters are prepd. by using esters of copal-resin acids with mono- or di-hydric alcs. as solvents or softening agents. In an example, nitrocellulose, Congo copal benzyl ester and a solvent of the acetone, AcOAc or AcOAm type are mixed, and the product is diluted with spirits, C_6H_6, etc. Other examples are given.

Cellulose esters. I. G. FARBENIND. A.-G. (Albert Gundlach and Theodor Becker, inventors). Ger. 516,250, Feb. 24, 1927. Esters of cellulose with higher homologs of AcOH are prepd. by treating cellulose or its conversion products with chloroacetic anhydride and higher homologs of AcOH in the presence of a catalyst, *e. g.*, H_2SO_4 or $ClCH_2COOH$. The soly. properties of the products can be improved by after-hydrolysis. Examples are given. Cf. *C. A.* 25, 1671.

Cellulose aliphatic acid esters. K. WERNER. Brit. 336,349, Aug. 15, 1929. In the production of cellulose aliphatic esters with preliminary removal of water from air-dried cellulose, before esterification, by treatment at temps. up to 50° with sufficient aliphatic acid and anhydride (such as acetic, propionic or butyric acids and anhydrides) to complete the esterification reaction, the removal of water is facilitated by the presence of a small quantity of catalyst insufficient to promote esterification such as H_2SO_4 0.02–0.05% or SO_2Cl_2 0.05% (calcd. on the wt. of the cellulose) and a milling process is preferably used for the pretreatment. Various details and examples of procedure are described.

Apparatus for cellulose acetate production. JEAN ALTWEGG (to E. I. du Pont de Nemours & Co.). U. S. 1,792,059, Feb. 10. An app. is described comprising a column having an inlet adjacent to one end and an outlet adjacent to the opposite end, and pro-

vided in its interior with rotatable stirring devices of varying form, which increase in size from inlet to outlet "according to the texture of the material to be treated" by these devices.

Apparatus for production of cellulose xanthate. M. DASSONVILLE. Brit. 337,149, July 1, 1929. Numerous structural details are described of a rotatable app. through the journals of which CS_2 may be fed to the reaction chamber and heating or cooling agents similarly fed to a jacket around the reaction chamber. Cf. *C. A.* **24**, 3646.

Hydroxyalkylcellulose xanthates in manufacture of artificial threads, films, etc. L. LILIENFELD. Brit. 335,993, March 25, 1929. Hydroxyalkylcellulose xanthates such as those described in Brit. 335,994 (following abstract) may be worked up into threads alone or with other materials such as cellulose xanthate or alkali-sol. derivs. of cellulose, gelatin, or softening or plasticizing agents, etc. (various examples of which are given). Numerous details of procedure are described for making products such as artificial threads and films, staple fiber, plastic masses, adhesives and cements, coatings and fabric dressings, artificial leather, transparent sheets, etc.

Xanthated hydroxyalkyl derivatives of cellulose. L. LILIENFELD. Brit. 335,994, March 25, 1929. Products of this type are produced by xanthating hydroxyalkyl derivs. of cellulose obtained either by the action of a hydroxyalkylating agent on cellulose in the presence of an alk. agent such as caustic alkali or by hydroxyalkylating alkali cellulose. Various halohydrins may be used as reagents and numerous examples, details and modifications of procedure are given. The final products may be isolated from the reaction masses or solns. (suitably after neutralizing with a weak acid such as HOAc) by pptn. with MeOH or EtOH, Al salts, NH_4Cl or $(NH_4)_2SO_4$, NaCl, Na_2SO_3, $NaHSO_3$, CO_2, SO_2, H_2SO_4 or HCl, or by dialysis. Catalysts such as salts of Cu, Ni, Ag, Zn or Fe may be added to the alkali cellulose or to the reactive mixt., and instead of NaOH or KOH there may be employed sulfonium hydroxides such as trimethylsulfonium hydroxide. "Near conversion products" of cellulose such as cellulose hydrate, hydrocellulose or oxycellulose may be used in the process.

Transparent celluloid stable to light. SCHERING-KAHLBAUM A. G. Brit. 336,980, Oct. 5, 1928. Celluloid of otherwise usual compn. contains a small proportion of added ingredients capable of combining with O compds. of N to form colorless non-injurious compds., such as urea or urethane.

Apparatus for treating viscose silk with liquids after spinning. ACME RAYON CORP. Fr. 694,971, May 3, 1930.

Tantalum spinneret. MINER M. AUSTIN (to Fansteel Products Co.). U. S. 1,791,785, Feb. 10. A Ta spinneret is provided with a hard resistant oxide film formed directly thereon to protect the spinneret against corrosion and wear.

Artificial fibers. I. G. FARBENIND. A.-G. (Harry Meyer, inventor.) Ger. 513,663, Nov. 15, 1928. Mat viscose fibers are produced from viscose to which the water-insol. liquid residues from the catalytic production of alc. have been added.

Device for connecting artificial threads to winding apparatus in the dry spinning process. J. E. PEDDER and COURTAULDS, LTD. Brit. 336,718, Aug. 21, 1929. Structural features.

Cellulose acetate yarn. CAMILLE DREYFUS and WILLIAM WHITEHEAD (to Camille Dreyfus). Can. 309,131, Mar. 3, 1931. Artificial textile products are produced by spinning a soln. of an acetone-sol. cellulose acetate in a solvent mixt. contg. 95.8% of acetone b. 56° and 5.2% of MeOH b. 64.5°.

Cellulose acetate yarns. CAMILLE DREYFUS and WILLIAM WHITEHEAD (to Camille Dreyfus). Can. 309,130, Mar. 3, 1931. Artificial textile materials are produced by spinning solns. of acetone-sol. cellulose acetate contg. less than 1% of moisture in a solvent mixt. of approx. 65% acetone and 35% denatured alc. contg. substantially 95% of EtOH.

Artificial silk. J. P. BEMBERG A.-G. Ger. 517,018, Nov. 8, 1927. In the manuf. of artificial silk from ammoniacal copper solns. of cellulose by stretch-spinning, the aq. pptg. bath contains a readily sol. gas, preferably a gas having a reducing action *e. g.*, SO_2 or H_2S. The bath may be preliminarily deaerated wholly or in part. Cf. *C. A.* **24**, 3901.

Artificial silk. I. G. FARBENIND. A.-G. (Hermann Schmidt and Emil Hubert, inventors). Ger. 516,370, June 12, 1926. Cuprammonium cellulose solns. are spun into pptg. baths contg. free CO_2 but no other dissolved gas.

Artificial silk. WM. P. DREAPER. Fr. 693,928, April 15, 1930. See Brit. 328,627 (*C. A.* **24**, 5496).

Artificial silk. RISUKE FURUSHO, YASUZO UTSUMI and ASAYUEMON TODA. Fr. 694,285, Apr. 22, 1930. The thread of artificial silk after desulfurizing, etc., is brought

into a coloring or bleaching soln. while still wet, then submitted to a tension to reduce its section while being drawn through a sizing soln., dried and wound on a reel.

Artificial silk. BARMER MASCHINENFABRIK A.-G. Fr. 694,309, April 23, 1930. The spinning cakes of artificial silk are given an interior conical shape of any thickness and the cakes are afterward placed on conical bobbins of the same slope for subsequent treatment.

Artificial silk. PIERRE L. É. V. BOURGEOIS. Fr. 694,531, April 25, 1930. In the prepn. of viscose for artificial silk, the wt. of fixed cellulose is increased by the addn. of flour or starch, etc., during the mixing of the xanthate with NaOH and water.

Artificial silk, films, etc. HENRY DREYFUS. Fr. 694,048, April 16, 1930. Finely divided SiO_2 is incorporated in the solns. of cellulose or its derivs. used for making threads, films, etc. Instead of SiO_2 an org. or inorg. silicate may be used which is afterward treated with HCl to produce SiO_2.

Artificial silk, films, etc. HENRY DREYFUS Fr. 694,119, April 17, 1930. In the manuf. of artificial silk, films, etc., a finely divided insol. substance such as $BaSO_4$, ZnO, $CaCO_3$ or insol. silicates is incorporated in the spinning soln. The dispersion of the insol. substance may be aided by protective colloids or oils such as Turkey-red oil.

Artificial silk, films, etc. I. G. FARBENIND. A.-G. Brit. 336,250, June 4, 1929. A true sulfonic acid (or a salt or other water-sol. deriv of such an acid) prepd. from a deriv. of an aliphatic or cycloaliphatic hydrocarbon contg. at least 8 C atoms, such as the sulfonic acid product derived from "tall oil" is added to cellulose or cellulose ester or ether or viscose solns. to improve the uniformity, softness and dyeing properties of the products formed.

Artificial silk, etc. H. DREYFUS. Brit. 335,894, May 31, 1929. Products such as filaments, films, ribbons or the like (suitably those from viscose, nitrocellulose or cuprammonium cellulose) are stated to be improved in strength and elasticity and modified as to luster, by subjecting them to the action of sulfo-carboxylic or other carboxy-organo-mineral acids contg. at least one free OH group and with one or more OH groups replaced by alkyl, aryl or aralkyl or other org. radicals one at least of which contains a carboxyl group (preferably of 30–50% concn.). Sulfoacetic, sulfosalicylic, sulfophthalic, sulfosuccinic or propane-β-carboxy-α-phosphinic acid may be used and some other acids also are mentioned. Other substances such as glucose, glycerol, Na_2SO_4, alcs. or sulfonated oils may be added to the treating baths.

Artificial silk, etc. L. LILIENFELD. Brit. 335,906, March 25, 1929. Artificial silk and other products are made by incorporating substances capable of providing one or more substituted or non-substituted alkyl, or hydroxyalkyl radicals (such as halogen derivs. of di- or polyhydroxy alcs.) with a cellulose deriv. contg. one or more CSS groups such as viscose, following this by a suitable shaping and treatment with an agent having a coagulating and plasticizing effect (or by successive treatment with agents having these effects separately). A cellulose-xantho-fatty acid or cellulose dixanthate may be used instead of viscose, and the plasticizing agent is preferably H_2SO_4 of at least 35% strength which may be mixed with HCl, HNO_3, H_3PO_4, H_3BO_3, HOAc, formic, lactic or oxalic acids, bisulfites, sulfites, and nitrites or aniline salts, glycerol, sugar or glucose. Numerous details, examples and modifications of procedure are described.

Improving the properties of artificial silk and similar products. H. DREYFUS. Brit. 336,217, March 28, 1929. Tensile strength, extensibility and elasticity of filaments, threads, fabrics or films, etc., comprising cellulose acetate or other cellulose esters or cellulose ethers are improved by treatment with neutral org. solvents in relatively high concn. so that a superficial filming or plasticizing of the material may occur. Among the solvents which may be used are acetone, diacetone alc., mono- or di-ethers of olefin glycols or polyolefin glycols, diethyl tartrate, ethyl lactate, phenols and mono- and di-acetins. The solvent is preferably assocd. with water, benzene or other non-solvent. Numerous details and examples are given.

Mordanting and weighting artificial silk. H. DREYFUS. Brit. 336,621, July 9, 1929. In mordanting and weighting materials such as cellulose acetate or other cellulose org. esters or ethers, one of the reagents for the mordanting or weighting is incorporated in the spinning soln. and the formed filaments are treated during or after their production with a reagent which will fix the desired metal compd. in the material. Compds. of metals such as Al, Cr, Fe, Sn, Zn, W and Bi may be used and if a pptg. agent such as tannic acid is added to the spinning soln. a compd. of the metal is preferably applied to the finished material or continuously with its production under such

conditions that swelling of the cellulose deriv. takes place. Various details and examples are given.

Esterification of wood. I. G. FARBENIND. A.-G. Brit. 336,969, July 22, 1929. Acylation of wood such as beech, aspen, fir or pine is effected with an anhydride of an org. acid such as acetic, butyric or benzoic anhydride, in the absence of inorg. catalysts. The wood may be used in dry disintegrated form or in the form of sheets which may be superficially acylated, and may be initially deresinified and dewaxed with solvents and treated with steam.

Treating bagasse fibers. ERNEST C. H. VALET (to Cellulosa Hemmer Valet, S. A.). U. S. 1,792,202, Feb. 10. In order to render bagasse fibers suitable for paper manuf., etc., they are treated with a clear satd. soln. of lime and there is subsequently added a soln. contg. a sulfite such as Na_2SO_3 and the fibers are then treated in a soln. of KOH, NaOH and a sulfite and are subsequently washed in a soap soln.

Sieve cylinder apparatus for dewatering cellulose pulp. J. STRINDLUND Brit. 336,879, June 11, 1929. Structural features.

Feltable bituminous pulps. CHARLES L. KELLER (to Richardson Co.). U. S. 1,792,098, Feb. 10. Fibrous material is subjected to a "pre-beating" to form a half stock and the latter is concd. to bring it to an easily handled plastic stage, transferred to a mixer, "premixed" with added bituminous material and the "premixed" stock is transferred to a beater and subjected to heating to prepare the fibers for felting, and production of a product in sheet form.

Nitrocellulose from wood-pulp board. N. PICTON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 336,235, May 27, 1929. Wood-pulp board is cut into substantially uniform pieces (suitably about one-eighth of an in. square) by a cutter which does not affect the agglomeration of the fibers and the pieces are nitrated with acid contg. not less than 40% HNO_3 to produce a nitrocellulose of high d. and uniform compn. suitable for the *manuf. of propellent explosives, blasting explosives, varnishes, celluloid,* etc. Various details of procedure are described.

Tanks and associated agitating apparatus for treating paper pulp. JOSEPH E BOND. U. S. 1,791,705-6, Feb. 10.

Dewatering paper pulp, etc. RICHARD KASTNER and HERBERT SCHMOLKA. Austrian 120,690, Aug. 15, 1930. Addn. to 115,901 (*C. A.* **24**, 2295). In the method of Austrian 115,901, the heating of the materials in the press is effected by passing an elec. current through the materials, the metallic sieves acting as electrodes

Dirt trap for paper pulp, etc. FRANZ HASSMANN. Ger. 516,212, June 3, 1928

Paper. I. G. FARBENIND. A.-G. (Rudolf Richter, inventor). Ger. 516,029, Aug. 12, 1928. Ornamental or effect paper is prepd by addn. of finely comminuted leather, colored or uncolored, to the paper stuff.

Paper stock. HARRY P. BASSETT. U. S. 1,792,351, Feb. 10. Cotton linters or similar material is subjected to a combined slight beating and acid treatment with a weak acid soln. such as a 0.05–1.0% soln. of H_2SO_4 at a temp. between 20° and 100° to effect partial hydrolysis of the material, and the latter is then treated with a weak alkali soln.

Recovering fibers from the waste waters of the paper, cellulose, etc., industries GEORG WATZINGER. Austrian 120,610, Jan. 15, 1930. A gas under pressure is dissolved or emulsified in the waste waters, and the pressure is then released so as to liberate bubbles of gas within the liquid. These carry the suspended fibers to the top of the liquid, whence they are removed. App. is described.

Paper-making machine [Fourdrinier type]. BELOIT IRON WORKS. Ger. 516,121, June 3, 1926. See Brit. 268,180 (*C. A.* **22**, 1238).

Suction box for paper-making apparatus, etc. GEORGE PEEBLES (to Selbec, Inc U. S. 1,791,535, Feb. 10.

Doctor blade mounting for paper machines. L. S. JOHNSON and F. W. VICKERY Brit. 336,554, May 14, 1929. Structural features.

Apparatus for reënforcing paper or other fabrics with unspun fibers. G. E. GIBBS (to American Reënforced Paper Co.). Brit. 336,830, Nov. 8, 1928. Structural features

Printing and waxing paper webs in a single operation. HARRY C. COLE. U. S. 1,792,414, Feb. 10. Various details of app. and operation are described.

Preparation for coating paper. SOC. I. F. LAUCKS, INC. Fr. 694,224, April 19, 1930. The prepn. is made by incorporating a mineral substance with a protein in the liquid state derived from oleaginous seeds. The seeds are freed from oil and extd with a feebly alk. salt such as Na_2SO_3 and the protein is pptd. with lime.

Apparatus for coating paper with wax. A. GREEN. Brit. 335,968, July 2, 1929. Structural features.

Sizing for paper. ARTHUR W. BURWELL (to Alox Chemical Corp.). U. S. 1,791,860, Feb. 10. A material for use in sizing paper consists essentially of water-sol. alkali metal salts of normally liquid water-insol., petroleum-insol., relatively high mol. wt. aliphatic and hydroxy-carboxylic acids such as those formed by oxidizing a paraffin-base fuel oil distillate and is capable of being retained in a paper in quantity up to 50% by wt. App. is described, suitable for oxidation of the oil.

Paper sizing. B. WIEGER (to Becker & Co. (1924), Ltd.). Brit. 335,902, July 1, 1929. Paper or pulp is sized with an emulsion prepd. by adding to the molten sizing material, while rapidly agitated, 1–3% of an aq. dispersion of a protective colloid (preferably alkali casein) and colophony is preferably employed as the sizing material, although there may be used other natural or artificial resins, solid or semi-solid hydrocarbons, waxes, fats, higher fatty acids or their mixts., with or without drying oils. Various details and examples are given.

Automatic device for regulating the drying of paper, etc., sheets. JOSEF MUCHKA. Austrian 120,248, July 15, 1930.

Drying cardboard, etc., by pressing. RICHARD PRÜCKNER. Austrian 120,700, Aug. 15, 1930. The press is housed in a casing having means for adjusting the temp. and pressure of the air in the casing. Operative features are described.

Water-resistant paper product. WM. C. LODGE (to Oswego Falls Corp.). U. S. 1,792,382, Feb. 10. There is added to the pulp sizing in the proportion of 3 parts rosin or rosin substitute and approx. 1 part wax or wax substitute, and a fixing or pptn. treatment is employed for the production of a final paper product contg. about 1% wax and not more than 3% rosin, which is suitable for bottle hood caps, etc.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE AND C. G. STORM

Report of Chief Inspector, Bureau for the Safe Transportation of Explosives and Other Dangerous Articles, for 1930. B. W. DUNN. *B. E. Report* No. 24, 83 pp. (March 3, 1931); cf. *C. A.* 24, 2296.—Only 15 minor accidents involving 2 injuries to persons and a total property loss of only $71 resulted during the transportation of *explosives* in the U. S. during 1930. None of these accidents was with com. blasting or military explosives, but involved toy torpedoes, fireworks, etc. In comparison, *inflammable liquids* caused 602 accidents with 9 deaths, 4 injuries and loss of $380,847, while *acids and corrosive liquids* caused 356 accidents, with 15 injuries and loss of $21,057. Defective tank cars carrying H_2SO_4 and faulty packing of HNO_3 were the causes of most accidents with acids. The report gives statistical details and contains much information of interest to manufacturers, dealers and consumers of explosives.

C. G. STORM

Static charges in smokeless powder. H. E. NASH. *Army Ordnance* 11, 293–6 (1931).—To est. the danger of ignition from static electricity in a smokeless powder dryhouse, expts. were conducted in a special unit of one tray, 36″ × 48″ × 6″, holding 100 lb. of powder, under varying conditions of moisture content of powder, and humidity, temp. and velocity of air current. Conclusion: (1) A moisture content of less than 1% is necessary for the existence of a measurable static charge. (2) A negligible amt. of static electricity exists on powder being dried in a heated air current. (3) Agitation of the powder causes larger static charges, but the max. charge is lower than that capable of causing ignition. With E. C. powder, the static found was less than $^1/_{10}$ that required to cause ignition. C. G. STORM

Variation of $\int p\,dt$ with loading density for different types of powders. H. MURAOUR AND G. AUNIS. *Compt. rend.* 192, 90-2(1931); cf. *C. A.* 25, 818.—The types of powder were a 20% centralite with a mixt. of nitrocotton 66, nitroglycerin 25, a 9% centralite powder made from the same mixt., a powder without centralite made from a mixt. of nitroglycerin 50, nitrocotton 50 and flake nitrocellulose powder. Various sizes of grains were used. Percent variation of $\int p\,dt$ is independent of grain size except for very low d. of loading with 50% nitroglycerin powder. A graph is given, with abscissas the inverse of max. pressure, ordinates the inverse of $\int p\,dt$, which shows that between 2500 and 3000 kg. max. pressure the inverse of $\int p\,dt$ is practically a linear function of max. pressure. E. M. SYMMES

Limits of inflammability of gases and vapors. H. F. COWARD AND G. W. JONES. Bur. Mines, *Bull.* 279, 114 pp.(1931); cf. *C. A.* 22, 2058.—This is a thoroughly revised and enlarged edition of this *Bull.* ALDEN H. EMERY

The ignition limits of hydrogen-air mixtures in the explosion bomb. Fr. Dieterlen. *Tech. Mech. u. Thermodynamik* 1, 429–34(1930).—Values of ignition limits of H-air mixts. given in the literature vary from 0.041 to 0.10 and from 0.60 to 0.80 parts H_2 by vol. for the lower and upper limits, resp.; this is mainly due to widely different app. used. In the tests made photography was used to det. the pressure-time diagram, and the movement of the flame front was recorded by spark photography with the Lindner app. (*Forschungsarb. Gebiete Ingenieurwesens* No. 326 (1930)). It was found that in addn. to the lower limit there was a combustion limit which is explained by the influence of convection. The proof thereof was obtained by variation of test conditions and Schlieren photographs. The characteristic reactions at the upper limit vary widely from those at the lower limit. An explanation is attempted by the use of the Schlieren photographs. E. M. Symmes

Nitration of diethylene glycol. Wm. H. Rinkenbach and H. A. Aaronson. *Ind. Eng. Chem.* 23, 160–3(1931).—Com. diethylene glycol contains usually about 5% ethylene glycol. The latter was removed by fractional distn. and freezing. Pure diethylene glycol has a f. p. of —11.5°, instead of —11.3° given in the literature. There were investigated the effects of the ratio of HNO_3 to H_2SO_4 in the mixed acid, the % H_2O in the mixed acid, the ratio of HNO_3 to diethylene glycol in nitration, the soly. of the dinitrate in spent acid, the effect of temp. in nitration, oxidation loss in nitration and purification losses. Diethylene glycol dinitrate is unstable in the presence of acid, is easily decomposed by heat and empirical heat tests are no more applicable than with nitroglycerin. Diethylene glycol dinitrate remained stable for 1 yr. at ambient temp. It is toxic, like nitroglycerin. E. M. Symmes

High brisance studies. III. Dynamite and Penthrinit in plastic and frozen states. Alfred Stettbacher. *Z. ges. Schiess-Sprengstoffw* 26, 8–10(1931); cf. *C. A.* 25, 1674.—Nitroglycerin, nitroglycol or gelatin Penthrinits frozen at a temp. as low as —40° are more brisant than when in liquid or plastic form, as shown by tests on 7 mm. Fe plates. At —75° to —80° glycol dinitrate merely deflagrates, blasting gelatin explodes with greatly reduced brisance, pure nitroglycerin explodes with unaltered effect, while Penthrinit exhibits increased brisance. S. believes that these differences in behavior cannot be satisfactorily explained by differences in chem. or phys. properties. The tests made serve to emphasize the high brisance of the Penthrinits under all conditions. C. G. Storm

Firedamp, its characteristics and detection. Colin McLuckie. *Iron Coal Trades Rev.* 121, 800–1(1930). The amt. and rate of emission of gas from coal were detd. They vary widely in different seams, varying from a trace to 8.8 cu. ft. per ton of coal in 48 hrs. in the samples reported. Sampling of the gas by means of rubber pump and balloon is described. Leslie B. Bragg

The testing of blasting caps. A. Haid and H. Koenen. *Z. ges. Schiess Sprengstoffw.* 25, 393–8, 433–9, 463–8(1930). The general principle proposed by Esop and developed by Wöhler (*C. A.* 21, 3744) of testing blasting caps against desensitized nitro compds. gives satisfactory results, provided test conditions are uniform. TNT of standard purity is screened through 0.5-mm. mesh with a duster screen of 0.15 mm. mesh. Talc was selected as the most desirable desensitizing agent, with specifications for screen test and settling test. The TNT and talc are intimately mixed in varying proportions, the talc content varying by 5% increments, and the mixts. are pressed at 1250 kg./cm.² in blocks 25 mm. in diam. and 41–2 mm. high, with a cavity for insertion of the blasting cap. These blocks do not become insensitive on storage as do mixts. contg. oils. The blocks are detonated on Pb plates 3 cm. thick, and the diam. of the depression is measured after filing the rough edges. This diam. decreases with increasing talc content until it is only the diam. of the block when the latter fails to detonate. The initiating effect of a blasting cap is measured by the percentage to which the talc may be increased before failure results. Straight $Hg(ONC)_2$ caps failed at 25% talc, compound TNT caps at 50% and tetryl caps at 65%. A series of tests was also made by the Cu cylinder method of Kast and the Trauzl Pb block test, which compare the effects of TNT charges desensitized with 30% talc when initiated with caps loaded to equal height with (*A*) $Hg(ONC)_2$ and $KClO_3$, 90/10; (*B*) $Hg(ONC)_2$; (*C*) TNT; (*D*) tetryl; (*E*) pentaerythritol tetranitrate. In *C*, *D* and *E*, priming charges of a mixt. of Pb trinitroresorcinate and PbN_6 were used. The order of brisance was found to increase from *A* to *E*. In every case, increased d. of charge in the caps gave higher brisance. The latter was shown to vary with the rate of detonation of the cap charge. Brisance is calcd. as $\Delta \times$ rate of detonation $\times (T/273) \times V_0$. General confirmation of the above relations was also obtained in tests of the caps alone on 7-mm. Pb plates. Variations in the form of the base of the cap (flat or concave) do not affect the initiating

effect of the cap as they do the results of the Pb plate test. Both Cu and Al caps gave substantially the same results. In studying the effect of variations in granulation of the TNT used in the desensitized charges, it was found that granulations from 0.15 to 0.50-mm. mesh showed equal sensitiveness (desensitization limit 40% talc); the same TNT pulverized to dust in a ball mill was more sensitive (50% talc); when it was fused and pulverized, its sensitiveness decreased (30–35% talc). Variations in pressures used in blocking the TNT-talc mixts. had a negligible effect on the results; with pressures from 750 to 2000 kg./cm.^{2} the desensitization limit was the same (40% talc). Lower pressures gave a decrease in sensitiveness. An app. is described and illustrated for cutting open blasting caps in order to remove the charge intact for examn. and analysis. C. G. STORM

Explosions occurring during the use of ethylene. FRANKLIN D. JOHNSON AND HUGH CABOT. *Arch. Surgery* **22**, 195–224(1931). JOHN T. MYERS

Under-water explosions—"torpedo" effect. M. TONEGUTTI. *Z. ges. Schiess-Sprengstoffw.* **25**, 446–7(1930).—Tests conducted by T. lead to conclusions exactly opposite to those of Stettbacher (*C. A.* **24**, 6018). Charges of 14 g. TNT (d. 1.4) and of 17 g. Penthrit 80/20 (d. 1.6) in cylindrical metal cartridges 21 mm. in diam. were detonated on 6.5-mm. Fe plates resting on an Fe cylinder enclosing a sealed air chamber. Tests were made in air and also with the entire app. under 0.5 m. of water. Photographs of the Fe plates show that with both explosives the under-water effect was appreciably greater than that obtained in air. C. G. STORM

Explosion in an acid-mixing plant. S. H. NEWMAN AND H. E. WATTS. *British Home Office Report* **1931**, 18 pp.—The explosion occurred in an acid-mixing tank in the plant of Hickson and Partners, Ltd., Castleford, Yorkshire, Eng., on July 4, 1930. HNO_3 (97–8%) was being added to 2–3 tons of H_2SO_4 (approx 80%) recovered from spent acid from the manuf. of mono- and di-nitro compds. of C_6H_6 and PhMe. Violent evolution of fumes was followed by flame and an explosion which caused much damage to the plant and the loss of 13 lives. Investigation showed that the storage tank from which the H_2SO_4 was drawn contained large quantities of a mixt of nitro compds. resulting from long accumulation. When HNO_3 was added to samples of these nitro compds. mixed with H_2SO_4, a marked rise in temp. occurred with a strong evolution of fumes. A mixt. of the nitro compds. (2 vols.) with HNO_3 (3 vols.) was highly combustible. Of this mixt. 376 g. was loaded in an 18-pounder steel artillery shell, provided with a booster of 50 g. tetryl, in which a no. 8 detonator was placed. On firing the latter, the charge detonated, causing fragmentation equal to that produced by picric acid. It was concluded that the reaction of the HNO_3 with the nitro compds. in the H_2SO_4 caused the explosion of the mixing tank. C. G. STORM

Nitro and amino compounds. Safe practices in production of explosives materials (AINSWORTH) **25.** Starch explosion hazards reduced by safety measures (PRICE, BROWN) **12.** Nitrocellulose from wood-pulp board (Brit. pat. 336,235) **23.** Recovery of HNO_3 (Can. pat. 308,879) **18.**

Explosives. CHARLES V. A. E. BARON. Fr. 694,466, July 29, 1929. Explosives are coated with coal or vegetable tar, petroleum, etc., by dissolving the coating substance in a suitable solvent such as CCl_4 or mineral oils, mixing with the explosive and heating, with stirring, in an autoclave. The solvent is afterward recovered by distn. under vacuum.

Explosives. WALTER FRIEDERICH. Fr. 694,057, April 16, 1930. Cyclic ketone-alcs. or cyclic alcs. such as tetramethylolcyclohexanone, tetramethylolcyclopentanone or octomethylolcyclohexanediol are converted into nitrates. The nitrates may be used alone or mixed with other explosives.

Explosives. OSKAR MATTER. Ger. 513,933, May 27, 1926. Pure, readily explosive Pb azide is prepd. by treating Na azide with alk. earth soln. (*e. g.*, $(AcO)_2Ba$) and then with $PbCO_3$.

Explosives. LEOPOLDO PARODI-DELFINO. Ger. 513,567, Oct. 30, 1925. Nitro powders, with or without a nitroglycerol content, are gelatined and stabilized by addn. of phthalide or homologs. Thus, artillery explosive may consist of nitrocellulose, nitroglycerol and phthalide.

Nitroglycerin. A. SCHMID and J. MEISSNER. Brit. 336,253, July 5, 1929. Sepn. of nitroglycerin from residuary acid is effected by passing the crude liquid through a vessel having an inclined longitudinal axis so that the particles move generally parallel to this axis, the acid downwardly and the nitroglycerin upward. Various details of app. and operation are described.

"Gas" cartridge. BYRON C. GOSS (to Lake Erie Chem. Co.). U. S. 1,792,010, Feb. 10. A compn. contg. gelatin and glycerol is used as the container material of cartridges such as those contg. an asphyxiating or disabling chemical to be fired from a pistol.

Fire-producing compositions. FERDINAND RINGER. Austrian 120,172, June 15, 1930. A fire-producing compn. cast in stick or rod form comprises a combustible base giving only a little ash, *e. g.*, cellulose nitrate or acetate, together with oxidizing agents and readily combustible substances, *e. g.*, $KClO_3$ and S, with, if desired, addns. for regulating the rate of combustion, *e.g.*, $(NH_4)_2C_2O_4$. The proportions of the ingredients are selected so that the stick or rod can be ignited by friction, blown out and ignited again as required. Glass powder, Carborundum or the like may be included to increase the sensitiveness to friction. A suitable compn. is cellulose nitrate 60–75, camphor 6–14, $KClO_3$ 11–20, $K_2Cr_2O_7$ 2.5, $(NH_4)_2C_2O_4$ 2.5, S 2.5, glass meal 5–15 and ZnO 3–10%.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

The chemistry of turkey-red dyeing. LYTLE R. PARKS. *J. Phys. Chem.* **35**, 488–510(1931).—The history of turkey-red dyeing is reviewed and the chemistry of the various operations studied. A new short process is proposed which gives a color just as bright and fast as any produced by the older methods. H. W. LEAHY

Nitro and amino compounds. Safe practices in production of dyestuffs and explosives materials. CYRIL AINSWORTH. *Am. Dyestuff Reptr.* **20**, 126–7(1931).—Prevention methods and remedies for poisoning by various nitro and amino compds. are given. ROBERT HOUGHTON

Formic acid in the textile industry. K. L. SCHANBACHER. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 76–9; *Am. Dyestuff Reptr.* **20**, 144–7(1931).—The use of HCOOH in the dye bath as a swelling agent, in cross dyeing and as an exhausting agent is discussed. MILTON HARRIS

Use and misuse of chlorine in textile bleaching. W. L. SAVELL AND J. W. IVEY. *Am. Dyestuff Reptr.* **20**, 97–100(1931).—Cl bleaches may be used from atmospheric temps. (cold) to 130°F. in the form of strongly alk. to slightly acid hypochlorites Bleaches are prepd. by dissolving Cl in caustic soda soln. $NaHCO_3$ is unsuitable and unnecessary as a constituent of bleach liquors. Stock solns. are generally made at a concn. of approx. 30 g. per l. of available Cl. MILTON HARRIS

Bleaching with liquid chlorine or hydrogen peroxide 100 volume for hosiery. G. H. DUBOIS. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 83–4; *Am. Dyestuff Reptr.* **20**, 151–2(1931).—A discussion of formulas and their sp. application in bleaching. MILTON HARRIS

The chemical analysis of sized cloth. G. SMITH. *Am. Dyestuff Reptr.* **20**, 118–22 (1931).—See *C. A.* **24**, 3115. MILTON HARRIS

Change of some properties of sericin particles on the surface of the (silk) cocoon on drying. H. KANEKO, T. HAYASHI, S. CHINO AND M. MIYASAKA. *Bull. Sericult Silk Ind.* (Japan) **2**, 2–3(1930).—During the drying of the cocoon the sericin particles on the surface undergo dehydration and their phys. properties change in such a way that the amt. of dyestuff absorbed is decreased and the surface tension, viscosity, n and turbidity and colloidal properties of the sericin soln. in water are altered. B. C. A.

Boiling-resistance tests of acetate silk. WALTER FERMAZIN. *Chem.-Ztg.* **55**, 93–4 (1931).—Methods are described for testing the resistance to boiling of acetate silk yarn Skeins are washed in ether, then tested by boiling for 1 hr. in distd. water and dried for 2 days at room temp. For testing breaking strength, elongation and elasticity, the boiled skeins are kept for 48 hrs. in 60% humidity, and 100 threads are then tested in the Schopper app. Elasticity values obtained by loading a weighted thread with an added weight equal to 50% of the breaking strength, and measuring the contraction on unloading, agree with the results of the other test. The depth of dyeing of skeins with standard dyes is compared with that of standard boiled skeins of varying resistance. The loss of gloss is detd. by Kempf's app., in which light is reflected from the threads onto a photographic film and the resultant brightening of the film is measured photometrically. I. H. ODELL

Determination of p_H of cotton cloth and study of its relation to tensile strength. S. I. KOLSKY AND B. M. JONES. *Am. Dyestuff Reptr.* **20**, 133–8, 157–9(1931).—Slight

decreases in p_H tender the cloth while increases tend to make it stronger. Ordinary bleached cloth was strengthened by treatment with dil. alkali. MILTON HARRIS

The effect of cleansing agents on linen and cotton. EMIL J. SIMOLA. *Acta Chem. Fennica* **3**, 89–94(1930).—One g. per l. of $MeCH_2SO_2NClNa \cdot 3H_2O$ has a little less weakening action on linen and cotton than has 0.5 g. per l. of perborate bleaching agent because of the greater stability of the former on boiling. A mixt. of 5 g. of soap with 3 g. per l. of soda weakened cotton 15% in 25 washings and 22% in 50 washings. For linen the values were 25 and 52%, resp. For soda alone (6 g. per l.) the values were 6 and 12%, resp., for cotton and 6 and 3%, resp., for linen. Ten g. per l. of Marseilles soap, with a water content of 26%, weakened cotton 16% in 25 washings and 28% in 50 washings, with values of 26 and 46%, resp., for linen. Soaps prepd. from linseed oils, soy-bean oils, Na and K stearates, oleates and palmitates showed that in water of 4 degrees hardness the greatest weakening of cloth occurred with soaps contg. acids of high I no. or high degree of unsatn. The cloth wt. increased in all washings, being greatest when water of a high degree of hardness was used. The weakening of cloth when distd. water, water of 4 degrees hardness and water of 25.4 degrees hardness were used were, resp., 5–15, 8–19 and 24–39%. For water of 4 degrees hardness the greatest weakening occurred with soaps contg. Na salts of acids of high I no. or high unsatn. as in soy-bean oil and linseed oil, being about 25% for cotton and 35% for linen in 25 washings. When soaps contg. Na salts of satd. acids as in coconut oil and tallow were used the weakening effect on cotton was 10% and on linen 15% in 25 washings. The drying of the cloth also greatly affects its strength, the weakening varying directly with the time necessary to dry. The cloth weakening was directly proportional to the amt. of Ca and Mg salts of unsatd. acid pptd. on the cloth fibers. These salts have some effect on the air oxidation of the cloth, and catalyze its autoxidation during drying; hence it is imperative that the cloth be dried as rapidly as possible. Ca and Mg salts must be prevented from forming, or, if this is not possible, they must be prevented from oxidation during drying of the cloth. Satd. acids will cause a pptn. on the cloth fibers, but the salts are not oxidized, and have less weakening action on the cloth. Satd. acids prepd. from unsatd. acids were difficult to purify, and discolored the cloth on long standing. Substances may be added which keep Ca and Mg salts in emulsion form and prevent pptn. on the cloth fibers. One cu. m. of water of 12 degrees hardness requires 2 kg. of Na soap to soften, and results in a pptn. of Ca and Mg salts, so the most effective method of preventing their formation is to soften the water preliminary to its use. Perborate solns. have about the same effect on cloth weakening as soaps contg. a high percentage of unsatd. acids. S. A. K.

Newer preparation for emulsifying, wetting out and washing. A. SALMONY-KARSTEN. *Z. ges. Textil-Ind.* **33**, 677(1930).—"Flerhenol M Superior" is described as a dyeing oil for rayon and rayon mixts. with silk and wool; "Flerhenol B T Special" is an anhydrous concd. product for degreasing vegetable fibers; "Appret-Flerhenol," a finishing oil stable with $MgSO_4$; "Neo Flerhenol," a wetting-out agent with unusual brightening and softening properties, "Visco-Flerhenol F" and "Visco-Flerhenol A" are for brightening and dyeing cotton and rayons; "Enfullon H" and "Enfullon Extra" for fulling and washing of woolens. All of these products are stable to hard water, easily sol., rinse well and are inexpensive. H. F. LEUPOLD

The photoelectric measurement of luster (DESBLEDS) **2**. Experiments with N fertilizers on cotton (MANDRUIGIN) **15**. Textile soap (HALBERSTADT) **27**. Purely aliphatic strepto-pentamethin dyes (KÖNIG, REGNER) **10**. Constitution of colorless and colored triphenylmethane derivatives (LIFSCHITZ) **10**. Protecting [textile materials] from fungi (Brit. pat. 336,244) **18**.

Annuaire des soies et des soies artificielles, 1930. Paris: L'Édition textile. 757 pp. F. 55. Reviewed in *Chimie & Industrie* **24**, 1287(1930).

HEGEL, K. T.: **Textilchemische Erfindungen. Lfg. 6.** Wittenberg: A. Ziemsen Verlag. Paper, M. 10. Reviewed in *J. Soc. Dyers Colourists* **47**, 40(1931). Cf. *C. A.* **24**, 3377.

Dyes. SCOTTISH DYES, LTD. Ger. 512,821, May 12, 1927. See Brit. 278,039 (*C. A.* **22**, 2667).

Dyes. I. G. FARBENIND. A.-G. (Wilhelm Eckert, inventor). Ger. 513,690, Oct. 23, 1928. N-contg. dyes are produced by nitrating naphthoylenediarylimidazole and

reducing the product. Thus, 1,4,5,8-naphthoylenedibenzimidazole (obtained by condensing 1,4,5,8-naphthalenetetracarboxylic acid with *o*-phenylenediamine as described in Ger. 430,632) is nitrated with HNO_3 and reduced with $Na_2S_2O_4$ to give a dye which colors cotton scarlet in a green vat. Other examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 337,021, June 21, 1929. Anthraquinone dyes for wool are made by condensing the Cu compd. of a 1-hydroxy-4-haloanthraquinonesulfonic acid with an alkyl-, aryl-, cycloalkyl-, aralkyl- or acylamino compd., the amino residue entering the 4-position. Suitable starting materials include acetyl-*p*-phenylenediamine, *m*-phenylenediamine and acetyl-*m*-tolylenediamine.

Vat dyes. L. CASSELLA & Co., GES. Brit. 336,495, Dec. 10, 1928. See Ger. 507,558 (*C. A.* **25**, 823).

Dyes. SOC. ANON. POUR L'IND. CHIM. Á BÂLE. Brit. 336,775, Oct. 3, 1929. Isodibenzanthrone is chlorinated (1) with $SbCl_5$ in $PhNO_2$ to form a blue-violet dye, (2) with sulfuryl chloride and I in $PhNO_2$ or (3) with Cl and I in $PhNO_2$, to form a similar dye, or (4) with $FeCl_3$ in trichlorobenzene, also forming a similar dye.

Dyes (dibenzanthrone derivatives). I. B. ANDERSON, R. F. THOMSON, J. THOMAS and SCOTTISH DYES, LTD. Brit. 336,268, May 9, 1929. By the alkali fusion of *Bz* 1,*Bz*-1′-dibenzanthronyls substituted by phenoxy, nitro or simple amino groups (but having the 2-position free) dyes are obtained producing reddish blue, greenish black or greenish gray shades on cotton. Several examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 336,938, July 10, 1929. Dyes are formed in substance or on the fiber (which may be regenerated cellulose or cellulose esters or ethers) by coupling a diazo, tetrazo or diazoazo compd. free from sulfonic, hydroxy and carboxy groups with a 2′,3′-hydroxynaphthoyl-4-amino-1-alkoxymethylbenzene. Numerous examples of coupling components are given.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 335,893, April 30, 1929. A diamine of the general formula NH_2—R—R′—R—NH_2 in which R is an aromatic and R′ a hydroaromatic residue (all of which may be substituted or not) is tetrazotized and coupled with 2 mol. proportions of the same or different coupling components one of which may be a diazo compd. or may be diazotized and coupled with another component. Numerous examples are given of dyes of different colors for dyeing wool, silk, etc.

Azo dyes. SOC. ANON. POUR L'IND. CHIM. Á BÂLE. Brit. 335,896, June 25, 1929. Cotton is dyed olive green in the presence of Cr salts by the dye produced by coupling 2-sulfo-4-oxy-α,β-naphthophenazine with diazotized 4-nitro-2-amino-1-phenol 6-sulfonic acid, and instead of the latter compd. there may be employed *o*-anisidine, *p*-nitroaniline, sulfanilic acid or *p*-nitroaniline-*o*-sulfonic acid. Various other dyes also are described derived from components of similar type, and methods are given for producing azo compds. used as intermediates.

Azo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD., and R. BRIGHTMAN. Brit. 336,350, Aug. 15, 1929. Azo dyes for wool are formed by coupling tetrazotized *m*-tolidine with one mol. proportion of salicylic acid and one mol. proportion of 2-naphthol-3-a 2-naphtholmonosulfonic acid, 2-naphthylamine-6-sulfonic acid or 2-methylamino-naphthalene-7-sulfonic acid. Cf. *C. A.* **25**, 599.

Azo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,730, April 29, 1930. New azo dyes are prepd. by diazotizing a *p*-nitroamine or a *p*-acetamidoamine of the C_6H_6 series contg. at least one alkoxy group in the mol., combining with a naphthol, naphtholsulfonic acid or a *N*-substituted 2,8-aminonaphtholsulfonic acid, reducing or hydrolyzing the product obtained, diazotizing again and coupling with a 1,8- or a 2,8-aminonaphtholmono- or di-sulfonic acid. Thus, 5-nitro 2 anisidine is diazotized and coupled with 2-phenylamino-8-naphthol-6-sulfonic acid. The product is reduced, diazotized and coupled with 1,8-aminonaphthol-2,4-disulfonic acid, giving a product which dyes viscose silk a deep blue. Other examples with a list of components and the colors obtained are given.

Azo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,559, April 26, 1930. Azo dyes are prepd. by coupling with coupling components a tetrazotized diamine of the general formula $NH_2C_6H_4NHXNHC_6H_4NH_2$ in which X is a chain of 2 or more CH_2 groups or a chain of CH_2 and CO groups, or by combining a diazotized amine of the general formula $YC_6H_4NHXNHC_6H_4NH_2$, in which X has the same significance and Y is a NO_2 or acylamino group, with a constituent which contains no NH_2 group, reducing the NO_2 group or hydrolyzing the arylamino group, diazotizing and coupling with another constituent. The dyes give regular colors on regenerated cellulose silk.

Copper compounds of azo dyes. I. G. FARBENIND. A.-G. Brit. 336,971, July 22, 1929. Substantive *o*-carboxyazo dyes contg. Cu are formed by the action of a copperiz-

ing agent such as $CuSO_4$ on dyes obtained by coupling tetrazotized 4,4′-diaminodiphenyl-3,3′-dicarboxylic acid with 2 similar or dissimilar mol. proportions of an aminonaphtholdisulfonic acid or a nuclearly substitution product of such an acid (other than acids substituted in the amino group). The dye may also be prepd. in the presence of a suitable coppering agent. The dyes thus formed produce mainly blue and gray shades on cotton and viscose. Several examples are given.

Monoazo dyes. I. G. FARBENIND. A.-G. Brit. 336,580, June 14, 1929. Monoazo dyes which dye wool from an acid bath bright yellow to red to violet to brownish shades fast to washing and to milling are formed by combining with a usual coupling component contg. at least one sulfonic group a diazotized aniline deriv. contg. a hydrogenated benzene nucleus in *p*-position to the NH_2 group and which may also contain a halogen atom or an alkyl or alkoxy group in *o*-position to the NH_2 group. Numerous examples are given.

Disazo dyes. E. I. DU PONT DE NEMOURS & Co. Brit. 336,646, July 12, 1929. Disazo dyes for cotton are made by coupling diazo compds. free from sulfo and carboxy groups with a *N*-aminobenzoylaminobenzoyl-J-acid, diazotizing the monoazo product and coupling it with a sulfo- or carboxy-indole. Numerous examples are given.

Disazo dyes. J. R. GEIGY A.-G. Brit. 337,224, Nov. 15, 1928. See Fr. 684,551 (*C. A.* **24**, 5507).

Disazo dyes. MELCHIOR BOENIGER (to Chemische Fabrik vorm. Sandoz). U. S. 1,792,355, Feb. 10. By coupling one mol. of a tetrazodiaryl with two mols. of 3′-amino-4′-methyl-5′-sulfo-1-phenyl-5-pyrazolones or by combination of the intermediate products of one mol. of a tetrazodiaryl and one mol. of an aryl-*o*-hydroxycarboxylic acid with one mol. of a 3′-amino-4′-methyl-5′-sulfo-1-phenyl-5-pyrazolone or by coupling the intermediate product of one mol. of a tetrazodiaryl and one mol. of a 3′-amino-4′-methyl-5′-sulfo-1-phenyl-5-pyrazolone with one mol. of an azo component substantive azo dyes are obtained, which when diazotized on the fiber can be developed with unsulfonated azo components (for instance β-naphthol, *m*-diamines, phenylmethylpyrazolone) to shades varying from orange to red, heliotrope and dark brown, which are fast to washing and can be discharged with formaldehyde-hyposulfite to pure white effects. The direct dyeings can also be fixed with formaldehyde or by an after treatment with *p*-nitrodiazobenzene. The same diazotizable azo dyes can be obtained by substituting, for the 3′-amino-4′-methyl-5′-sulfo-1-phenyl-5-pyrazolones, the corresponding 3′-nitro-4′-methyl-5′-sulfo-1-phenyl-5-pyrazolones, and by reducing in the nitro dyes thus obtained the nitro group to the amino group by treatment with NaS. Several examples with details of procedure are given.

Diazo dyes for acetylcellulose. BRITISH DYESTUFFS CORP., LTD., JAMES BADDILEY and JAMES HILL. Ger. 513,763, Nov. 9, 1926. See Brit. 270,428 (*C. A.* **22**, 1692).

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz, Karl Köberle and Erich Berthold, inventors). Ger. 516,313, Apr. 28, 1929. Green-blue vat dyes contg. halogen are prepd. by treating benzanthronepyrazoleanthrone or its derivs. with $HClSO_3$ in the presence of a catalyst, *e. g.*, Hg or I, and in the presence or absence of Br or other brominating agent. The products give greener shades than the dyes described in Ger. 492,274 (*C. A.* **24**, 2611). Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Heinrich Neresheimer, inventor). Ger. 516,784, Aug. 18, 1929. Addn. to 513,046 (*C. A.* **25**, 1396). Blue to green vat dyes similar to some of those obtainable as described in Ger. 513,046, are prepd. by the action of acid condensing agents on α-anthraquinonyl-3-amino-1,2-benzanthraquinones contg. at least one acylamino group, which may be split off or substituted after the condensation. Thus, the condensation product from 3-chloro-1,2-benzanthraquinone and 1-amino-5-benzoylaminoanthraquinone may be treated with $HClSO_3$. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 694,152, April 18, 1930. The 4 H atoms of the C_6H_6 ring in anthraquinone-2,1-acridone are substituted by halogen atoms. The dyes are prepd. after the process of Ger. 267,211, *e. g.*, by condensing the benzylic ester of 1-chloroanthraquinone-2-carboxylic acid with 2,3,4,5-tetrahaloaniline and a final joining of the acridone ring, or by introducing other halogen atoms into anthraquinoneacridones, the C_6H_6 ring of which is substituted by less than 4 halogen atoms, or by substituting with H the halogen contained (in addn. to 4 atoms of halogen of the C_6H_6 ring) in another part of the mol. of the haloanthraquinoneacridones. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 693,997, April 15, 1930. The mixts. of isomeric 1,4,5,8-naphthoylenediarylimidazoles obtained by the process of Fr. 600,843

and its addns. are sepd. into their 2 constituents. The sepn. is effected by treatment with concd. H_2SO_4 or by transforming them in the presence of an appropriate diluent into their salts and sepg. these. Examples and formulas of the products obtained are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 693,949, June 14, 1929. The condensation products obtained from *N*-dihydro-1,2′,2,1′-anthraquinonazines by means of CH_2O or substances yielding CH_2O (cf. Fr. 346,398) are submitted to an oxidation or dehydrogenation. Examples are given.

Vat dyes of the thioindigo series. KARL THIESS, THEODOR MEISSNER and HANS HEYNA (to General Aniline Works). U. S. 1,792,130, Feb. 10. 4,7,4′,7′-Tetramethyl-5,5′-dibromoindigo and other similar halogen compds. dye cotton blue from an olive-green vat and are made by transforming amino compds. of the general formula

$CX:CMe.CY:C(NH_2).CMe:CH$ wherein X stands for halogen and Y stands for H or the COOH group, into indigo dyes according to the process generally used for the prepn. of indigo dyes from aromatic amino compds. with a free *o*-position, or from *o*-aminocarboxylic acids. Several examples with details of procedure are given.

Vat dyes or intermediates. I. G. FARBENIND. A.-G. (Walter Mieg and Robert Berliner, inventors). Ger. 516,398, Dec. 9, 1928. Dianthraquinonylamine derivs. contg. a thioxanthone ring and either one acylamino group or an acridone ring is treated with H_2SO_4 at a low temp. Oxidation of the products may be necessary. Thus, the condensation product from 4-aminoanthraquinonethioxanthone and 1 benzoylamino-5-chloroanthraquinone may be treated with H_2SO_4 at 20° and the product poured into water contg. a little $NaNO_2$. Other examples are given also. The products are carbazole derivs. Cf. *C. A.* **25**, 824.

Dyes and intermediates. W. SMITH, J. THOMAS and SCOTTISH DYES, LTD. Brit. 336,982, April 16, 1929. 1,1′-Dianthraquinonyl derivs. contg. Cl, Br or sulfonic acid groups in the 2,2′-positions are prepd. by condensing anthraquinone derivs. contg. similar groups in the 2-position and a halogen atom or diazo group in the 1-position in the presence of Cu. There may be employed as starting materials compds. such as 1,2-dichloroanthraquinone, 1-amino-2-bromoanthraquinone or 1-amino-2-sulfoanthraquinone. The 2,2′-substituents in the products are easily replaceable by other substituents, *e. g.*, treatment with NH_3 forms 2,2′-diamino-1,1′-dianthraquinonyl which is converted to flavanthrone.

Dyes and intermediates. I. G. FARBENIND. A.-G. (Max A. Kunz, Karl Köberle and Gert Kochendorfer, inventors). Ger. 516,399, Feb. 16, 1929. See Fr. 689,908 (*C. A.* **25**, 1100).

Dyes and intermediates. I. G. FARBENIND. A.-G. Fr. 694,853, May 2, 1930. Condensation products, some of which are dyes and intermediates, are prepd. by treating with condensing agents the products resulting from the reaction of aromatic *o*-aminocarboxylic acids, their derivs. or substitution products with negatively substituted heterocyclic compds. or with negatively substituted isocyclic compds. contg. at least 4 rings, or the corresponding products resulting from the reaction of heterocyclic or isocyclic *N* compds. contg. at least 4 rings and having at least one atom of H capable of being substituted fixed to the N, with aromatic carboxylic acids, negatively substituted in the *o*-position to the COOH group, or their derivs. or substitution products. Thus, the condensation product of dibromo-3,4,8,9-dibenzopyrene-5,10-quinone with 2 mols. of the Et ester of 1-aminoanthraquinone-2-carboxylic acid is dissolved in concd. H_2SO_4 and heated to 110–120° for some time, the oxonium salt of the product being pptd. by water. On hydrolysis a product is obtained which dyes cotton in brown red shades from the vat. Other examples are given.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 336,394, Sept. 27, 1929. *p*-Arylaminophenolcarboxylic acids are made by treating a dry alkali salt of a *p*-arylaminophenol contg. a free *o*-position to the OH group and no sulfonic acid groups with CO_2 with use of heat and pressure. There may be used as starting materials: 4-hydroxydiphenylamine, 4-hydroxy-2′-methyldiphenylamine, 4-hydroxy-3′-methyldiphenylamine, 4-hydroxy-4′-methyldiphenylamine, 4-hydroxy-3-methyldiphenylamine (obtained from toluhydroquinone and aniline), 4-hydroxy-3,4′-dimethyldiphenylamine (obtained from toluhydroquinone and *p*-toluidine), and 4-hydroxy-3′-methoxydiphenylamine.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 336,428, Oct. 14, 1929. Arylides of *m*-arylaminophenolcarboxylic acids such as those obtained according to the process of Brit. 333,783 (*C. A.* **25**, 603) are made by reaction of the carboxylic group

(with or without previous acylating of the N atom) with an arylamine in the presence of an acid-condensing agent such as PCl_5 and a diluent such as xylene, toluene, PhCl or dimethylaniline; or, the carboxylic acid may be first converted to the acid chloride by a reagent such as thionyl chloride and then condensed with an arylamine in the presence of a diluent. Numerous examples are given.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 336,800, Oct. 18, 1929. Dihydroxyanilides of naphthalenedicarboxylic acids, capable of being coupled with a diazo compd., are made by condensing a naphthalenedicarboxylic acid (other than a *peri* or an *ortho* acid) in the presence of PCl_5 (or by using a naphthalenedicarboxylic acid chloride directly) with a hydroxyarylamine which has a free *o*- or *p*-position relative to the OH group such as 3- or 4-aminophenol, 1-methyl-2-amino-4-hydroxybenzene, 1-methyl-2-amino-5-hydroxybenzene or the like. The alkali salts of the products are sol. in water and have an affinity for vegetable fibers. Naphthalene-1,4- and 1,5-dicarboxylic acid chlorides (which may be used as initial materials) are made by treating the corresponding acids with PCl_5.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 337,047, July 26, 1929. Aminohydroxyanthraquinones and their substitution products are obtained by condensing an acyl- or aroylaminophenol, or a homolog or substitution product, with phthalic anhydride, or a substitution product, in the presence of a substance such as $AlCl_3$, saponifying, and ring closing when necessary in the usual manner. Examples are given of the production of 2,3-aminohydroxyanthraquinone from 2,2'-dimethoxydiphenylurea, 1-amino-4-hydroxyanthraquinone from 1-benzoylamino-4-phenol and of several other similar reactions.

Dye intermediate (1-chloromethylnaphthalene). I. G. FARBENIND. A.-G. Brit. 337,289, Jan. 12, 1929. Cryst. naphthalene in aq. suspension is treated with nonpolymerized formaldehyde and concd. HCl (suitably with gentle heating).

Intermediates for azo dyes. I. G. FARBENIND. A.-G. Ger. 516,156, Feb. 8, 1929. Nitroaryl arylides of the formula $HORNHCOR'NO_2$, in which R and R' are the same or different aryl radicals of the C_6H_6 series, and in which the NO_2 group is in the *m*- or *p*-position to the CO group, while the *o*- or *p*-position to the OH group is unsubstituted, are converted by treatment with alk. reducing agents into new compds. having a great affinity for cotton. The products are believed to be azoxy or azo compds. Examples are given.

Dyes of the anthraquinone series. FRANZ ACKERMANN and CARL APOTHEKER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,792,348, Feb. 10. Reaction products such as those formed by heating, at 150–160°, aromatic amines such as $PhNH_2$ or *p*-anisidine with compds. such as (1,5- or 1,8)-diamino-(4,8- or 4,5)-dinitroanthraquinone, are subjected to careful reduction (suitably with Na sulfide or hydrosulfide), and there are thus obtained dyes sol. in various org. solvents and which are suitable for dyeing cellulose esters and ethers or products such as nitrocellulose lacquers blue to blue-green shades. Several examples with details of procedure are given.

Fuchsin dyes. HEIDELBERGER GELATINE-FABRIK STOESS & Co. (Albert Steigmann, inventor). Ger. 513,610, Dec. 14, 1928. Fuchsin dyes are produced by oxidizing and nitrating fuchsin in the presence of sulfurizing agents and optionally reducing the product. Thus, fuchsin is mixed with $Na_2S_2O_3$ or $Na_2S_2O_4$ and treated with HNO_3 and H_2SO_4. The Na and NH_4 salts of the dye color wool yellow in a weak AcOH bath. Another example is given. Cf. *C. A.* **24**, 4639.

Sulfur dyes. I. G. FARBENIND. A.-G. Brit. 336,061, Sept. 2, 1929. Sulfur dyes are made by sulfurizing a 2-(4'-hydroxyarylamino)-6-arylaminonaphthalene (suitably with a polysulfide of high S content and in the presence of an inert org. solvent such as an aliphatic alc. of high b. p., a cyclic alc. or glycerol). The dyes produce bluish to green shades on cotton from a Na sulfide bath or hyposulfite vat, and greener shades are obtained by sulfurizing in the presence of a Cu salt such as the sulfide or cyanide. Several examples are given.

Sulfuretted dyes. I. G. FARBENIND. A.-G. Brit. 337,061, July 27, 1929. The S dyes obtainable, as described in Brit. 325,519 (*C. A.* **24**, 4169), by heating halogenated dinaphthylene dioxides with S, with or without a high boiling diluent, or by submitting them to polysulfide fusion, are treated either in substance or on the fiber with alkylating or aralkylating agents as described in Brit. 317,776 (*C. A.* **24**, 2306). Several examples are given.

Wool dyes. I. G. FARBENIND. A.-G. Fr. 694,088, April 17, 1930. One mol. of a secondary amine of the C_6H_6 series contg. 2 primary NH_2 groups in position *o*- with respect to the secondary amine group and at least one SO_3H group is heated with one

mol. of the C_6H_6 series contg. 2 NO_2 groups in *o*-position and a NO_2 group in *p*-position with respect to an exchangeable atom or atomic group. Thus, 2,6-diaminodiphenylamine-4-sulfonic acid is dissolved in water and the neutralized soln. is condensed at 70–80° with 2,4,6-trinitroanisole in the presence of Na_2CO_3. The product is pptd. by NaCl and dyes wool in yellowish brown shades. Other examples are given.

Anthanthrone derivatives. I. G. FARBENIND. A.-G. (Max A. Kunz, Karl Köberle and Erich Berthold, inventors). Ger. 516,312, Aug. 10, 1928. See Fr. 678,055, (*C. A.* **24**, 3248).

Dibenzopyrenequinones. GEORG KRÄNZLEIN and HEINRICH VOLLMANN (to General Aniline Works). U. S. 1,792,169, Feb. 10. Vat dyes are formed by the reaction (with introduction of O into the reaction mixt.) at temps. of 110–50° of α-benzoylnaphthalene or other suitable α-aroylnaphthalenes with benzoyl chloride or other suitable compd. of the general formula: aryl—CO—X (in which X stands for a halogen atom or for the group —O—CO—aryl, as in aromatic carboxylic acid chlorides or carboxylic anhydrides), in the presence of $AlCl_3$. The reaction may require 20–60 hrs. Examples and details of procedure are given.

Diphthaloylnaphthalene. I. G. FARBENIND. A.-G. Fr. 694,890, May 2, 1930. 1,2,5,6-Diphthaloylnaphthalene, m. 410°, and its substitution products are prepd. by treating 2′,2″-dicyano-1,5-dibenzoylnaphthalene with an acid-condensing agent. If desired the cyano groups may first be changed to COOH groups. With sufficiently moderate conditions 2′-carboxybenzoylnaphthanthraquinone may be obtained as an intermediate product. The prepn. of 1,2,5,6-(2′2″-dichlorodiphthaloylnaphthalene), m. above 400°, is also described. The products are *intermediates for dyes.*

Dyeing with vat dyes. I. G. FARBENIND. A.-G. (Ludwig Löchner, inventor). Ger. 513,526, Sept. 12, 1928. Polychromatic effects are produced by using ester salts of vat dyes. The goods are impregnated with an alk. soln. of 2,3 hydroxynaphthoic acid arylides, and printed out successively with aromatic diazo compds. of vat dyes, with addn. of $NaNO_2$. The vat dye is developed in the dried goods by acid and the rolled goods are then scoured and treated with a hot dil. alk. soln. A small quantity of reducing agent such as CH_2O, glucose, etc., may be added to the vat dye printing paste. In an example, the goods are soaked in a soln. contg. 2,3-hydroxynaphthoyl-*o*-toluidine, Turkey-red oil and NaOH, and dried. For red shades, the goods are printed out with a paste contg. the diazo soln. from 4-chloro-2-toluidine-HCl, water, $NaNO_2$, AcONa and starch. For blue shades the material is printed out with a soln. contg. ester salts of tetrabromoindigo, $NaNO_2$, water and starch. Several other examples are given.

Dyeing or treating threads. HENRY DREYFUS. Fr. 694,880, May 2, 1930. Liquids such as size or dyes are applied to threads while they pass below the edge of an annular or cylindrical member serving to guide the thread to a bobbin or cake of thread.

Dyeing cotton. ORANIENBURGER CHEMISCHE FABRIK A.-G. (Kurt Lindner, Rudolf Kuhn and Max Trapke, inventors). Ger. 513,843, Jan. 11, 1924. Dyes, especially naphthol dyes, are applied directly to cotton, the process being carried out in the presence of hydrogenated phenols and nonsulfonated soap in the proportions 1 or less:4. Thus, the azo dye from dianisidine and 1-amino-8-naphthol-4-sulfonic acid (Chicago blue B) is used directly to color cotton blue in the presence of coconut oil, oleic acid and cresol. Other examples are given.

Dyeing wool yarn. FIRMA H. KRANZ. Ger. 513,662, April 24, 1927. Details are given of app. for receiving the spools and supplying the dye liquor.

Dyeing artificial silk. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,856, May 2, 1930. Textiles of regenerated cellulose are dyed regular blue shades by applying to the textile a diazo dye obtained by coupling a diazotized aminoazo compd. with a 1,8- or 2,8-aminonaphthol-mono- or -di-sulfonic acid, the aminoazo compd. being obtained by coupling with a naphthol or naphtholsulfonic acid or with a *N*-substituted deriv. of 2,8-aminonaphtholsulfonic acid, either diazotized *p*-nitroaniline (or a substituted deriv. excepting alkoxy derivs.) or diazotized *p*-aminoacetanilide (or a substituted deriv. excepting alkoxy derivs.), the coupling being followed by reduction of the NO_2 group in one case or hydrolysis of the acetylamino group in the other. Examples and a list of components with the colors obtained are given. Fr. 694,857 describes a process for obtaining regular dyes on textiles of regenerated cellulose by applying to the textile a monoazo dye obtained by diazotizing an oxamic acid of the benzidine series and coupling with a naphtholsulfonic acid, a sulfonic acid of naphthylamine, 1,8-aminonaphtholsulfonic acid, 1,8-dihydroxynaphthalenesulfonic acid, *m*-dihydroxybenzene deriv., *m*-diaminobenzene deriv. or *m*-aminohydroxybenzene deriv. Examples and a list of components with the colors obtained are given. Cf. *C. A.* **25**, 1685

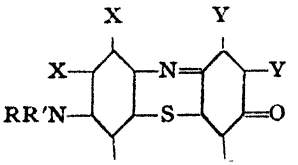
Dyeing cellulose esters or ethers. I. G. FARBENIND. A.-G. (Wilhelm Eckert, Carl E. Müller and Walter Gmelin, inventors). Ger. 516,982, Feb. 2, 1929. Addn. to 515,029 (*C. A.* **25**, 1685). The method of Ger. 515,029 is modified by using naphthalimide-4-sulfamic acid or the corresponding derivs. or their salts instead of 4-aminonaphthalimide or the derivs. mentioned. Examples are given.

Dyeing skins, furs, feathers, etc. I. G. FARBENIND. A.-G. (Karl Marx and Karl Bittner, inventors). Ger. 513,525, Apr. 14, 1927. Use is made of a soln. contg. an oxidizing agent and a salt of the base *p*-$RC_6H_4NHC_6H_4NH$-alkylene-OH-*p'*, where R = H, CH_3, OCH_3 or halogen. The material may be mordanted. In the example, skins are treated with an aq. soln. of H_2O_2 and 4-hydroxyethylaminodiphenylamine-HCl to produce a yellowish tint when mordanted with Fe alum. A blue-violet color is given by 4-hydroxyethylamino-4'-methoxydiphenylamine-HCl.

Skein-dyeing apparatus. J. SCHUMPF. Brit. 336,174, Dec. 27, 1928. Structural features.

Apparatus for dyeing width fabrics. O. OBERMEYER. Brit. 336,724, Aug. 26, 1929. Structural features.

Apparatus for dyeing cloth webs. WM. E. CAFFRAY (to Nashua Mfg. Co.). U. S. 1,791,954, Feb. 10. Various structural details are described.



Apparatus for dyeing ribbons, etc. H. A. BLUNDELL and BLUNDELL BROS. (LUTON), LTD. Brit. 336,686, July 23, 1929. Structural features.

Extracting dyes from dyed artificial materials. WM. WHITEHEAD (to Celanese Corp. of America). U. S. 1,791,990, Feb. 10. Dyed materials formed from artificial org. cellulose derivs. such as cellulose acetate are treated with a soln. such as C_2HCl_3 together with about 2% of acetone, which acts as a swelling agent for the cellulose deriv. material and a solvent for dyes present.

Reduction products of dyes. I. G. FARBENIND. A.-G. Fr. 693,904, April 14, 1930. Stable reduction compds. which are difficultly sol. in aq. alkalies are prepd. by submitting to an alk. reduction the symmetrical or asymmetrical dyes of the thioindigo series which are substituted in their mol., at least once, by a halogen, alkyl or alkoxy group, the alkali being present in amt. less than that used practically for the prepn. of the vat dyes in question. Several examples are given.

Printing textiles. I. G. FARBENIND. A.-G. Fr. 693,996, April 15, 1930. Textiles are printed with stable reduction products of thioindigo dyes prepd. by the process described in Fr. 693,904 (preceding abstr.) and then treated in the usual manner. Examples are given. Cf. *C. A.* **25**, 1391.

Textile printing. I. G. FARBENIND. A.-G. Fr. 694,643, April 28, 1930. Fast printings are obtained on vegetable fibers by direct printing in the usual way with dyes of the formula:

in which R' is an aryl ring which may be substituted, R is H or an alkyl or aralkyl group, X is H or a univalent substituent, Y is H or a univalent substituent, particularly a halogen. These dyes are described in Ger. 445,270.

Printing. I. G. FARBENIND. A.-G. (Albrecht Schmidt and Ernst Pfeffer, inventors). Ger. 515,305, Jan. 5, 1929. Prints obtained from vat dyes with the aid of methyl cellulose are fixed, without steaming, by means of a salt bath contg. alkali and a reducing agent, *e. g.*, hyposulfite. Examples are given.

Coloring textiles. HENRY DREYFUS. Fr. 694,750, April 29, 1930. The solidity of dyes on textiles, etc., particularly anthraquinone derivs. contg. NH_2, alkylamino or arylamino groups, is improved by incorporating in the textiles before, after or during their dyeing, one or more urea bases such as diisoamylthiourea or tetramethylthiourea. A dispersion agent and a protective colloid may also be added. Fr. 694,751 describes a similar process in which one or more alkylated diarylamino bases such as tetraalkyldiaminodiphenylmethane (or ethane) are used. Cf. *C. A.* **25**, 1685.

Colored reserves in textile printing. I. G. FARBENIND. A.-G. Brit. 336,968, July 22, 1929. Colored reserves are obtained by incorporating with the reserve, com-

prising essentially one or more metallic salts, a previously prepd. mixt. of an aryl nitrosamine compd. of an arylide of 2,3-hydroxynaphthoic acid or of acetoacetic acid ("Rapid Fast Colors"), the dye formation being completed by steaming or hanging, followed by dyeing of the material with a vat dye, and finishing in the usual manner. Details of materials used are given.

Colored patterns on cellulose acetate materials. GEORGE H. ELLIS and ERNEST GREENHALGH (to Celanese Corp. of America). U. S. 1,792,152, Feb. 10. The material is locally treated with a compn. comprising a swelling agent for the acetyl cellulose and a substance such as a printing color compn. capable of effecting a desired color change. Various details and examples are given.

Impregnating fibers. LOUIS C. F. PECHIN. Fr. 694,690, April 30, 1930. Fibers or ligneous materials are impregnated with resins using only a vacuum during impregnation and then polymerizing or hardening the resins by direct treatment in a suitably heated oil bath.

Impregnating textile fibers. GERHARD SCHMITT. Ger. 513,592, April 27, 1927. The fibers are impregnated with a colloidal soln. of powd. montan wax, resin and calcined soda obtained by using hot water or steam. Other oils, fats, waxes, asphalt, pitch, etc., may be added.

Mercerizing vegetable fibrous materials. EMIL GMINDER. Ger. 516,069, Dec. 1, 1925. The materials, after treatment with acid or alkali, are simultaneously cooled and stretched. App. is described.

Machine for stripping tissue from vegetable fibers. I. G. FARBENIND. A.-G. (Ernst Wiss and Karl Erb, inventors). Ger. 513,816, Sept. 18, 1927.

Improving the color of jute fibers. JOSEPH BERLINERBLAU. Ger. 513,374, Nov. 23, 1928. See Fr. 684,964 (*C. A.* **24**, 5511).

Apparatus for treating textile materials with circulating liquids. C. F. HAMMOND and W. SHACKLETON. Brit. 336,963, July 22, 1929. Structural features.

Combined singeing and warping apparatus for treating yarns. STANDARD-COOSA THATCHER CO. Brit. 335,916, June 29, 1929. Various structural details are described of an app., the burners of which are automatically turned off when the app. stops or when a stop-motion is operated by breakage of the yarn or by passage of a measured length.

Pile fabrics. COLLINS & AIKMAN CORP. Brit. 336,553, April 9, 1929. Pile fabrics are woven with less than the customary number of threads in the backing and the latter is impregnated with materials such as rubber, viscose or pyroxylin solns. which are solidified as by coagulation, vulcanization or heating. Various features of decoration, etc., are mentioned. Cf. *C. A.* **25**, 606.

Silk-faced fabric. A. DELUBAC. Brit. 336,067, Sept. 7, 1929. Silk cocoons are opened out and flattened and are sewed or otherwise attached to a backing fabric such as calico, silk or linen, and the material is then subjected to the action of a bath which dissolves the sericin without attacking the fibroin such as a boiling soln. contg. soda 140 g. in water 100 l., followed by washing in hot water, drying and brushing, combing or beating to raise the fibers.

Artificial silk. GLANZSTOFF-COURTAULDS G. M. B. H. Fr. 694,516, April 25, 1930. The liquid for treating cakes of artificial silk is introduced at the interior of the cake which rests on a fixed support and the overflowing of the liquid over the edge of the cake causes a loosening of the layers of thread.

Artificial silk and wool. I. G. FARBENIND. A.-G. Fr. 693,921, April 15, 1930. Artificial silk and wool are made from the polymerization, condensation and transformation products of butadiene hydrocarbons obtained in the presence of solvent agents.

Apparatus (with perforated drums) and suction system for drying cotton or wool slivers. J. E. FLEISSNER and E. FLEISSNER (trading as C. Fleissner & Sohn). Brit. 336,540, Feb. 23, 1929.

Removing cotton linters, etc., from closed kiers. J. P. BEMBERG A.-G. Ger. 516,068, Dec. 16, 1928. The treating liquid is run off, and the cotton is agitated with water by blowing in air at atm. pressure until a uniform pulp is obtained. The pulp is then forced out through an ascension tube by means of compressed air.

Horsehair substitute. EGON ELÖD. Fr. 694,683, April 29, 1930. Hard vegetable fibers, such as coconut fibers are heated with dil. lyes, *e. g.*, 7–8% NaOH in a closed vessel to 120–135°, and then treating with oily or hygroscopic substances.

Apparatus for reclaiming used petroleum products such as "dry cleaning" solvents by chemical treatment. CLARENCE V. FUQUA. U. S. 1,791,809, Feb. 10. Structural features.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Desirable properties in paints for toys. W. ADLER. *Farbe u. Lack* **1931**, 65, 76–7.—Suitable pigments of a wide range of colors for use in aq. and non-aq. media are discussed. G. G. SWARD

Adhesion in the painting and in the gluing of wood. F. L. BROWNE. *Ind. Eng. Chem.* **23**, 290–4(1931).—To improve materially, the durability of house paints on wood means must be discovered for making coatings adhere permanently so that they will wear away instead of falling off in pieces (cf. *C. A.* **24**, 2313). Scientific approach to the problem requires a study of the nature of the adhesion between coatings and wood. There are essential similarities between coatings clinging to wood surfaces and layers of glue joining surfaces in glued wood joints. Knowledge already gained about the adhesion between glue and wood (*C. A.* **21**, 3485; **23**, 1304) may therefore serve as a useful guide in the study of adhesion between coatings and wood. F. L. BROWNE

Notes on lead tungate. H. A. GARDNER. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. **377**, 133–4(1931).—Pb tungate as a vehicle for quick-drying paints may be prepd. by adding 30 parts litharge or 35 parts basic Pb carbonate to 100 parts of tung oil fatty acids at 300° F. The paste so prepd. is thinned while hot, preferably with solvent naphtha. Pb tungate so prepd. is sol. in a no. of common solvents while hot but gradually ppts. from these solns. on standing after cooling. Apparently its pptn. does not preclude its use in paints. G. G. SWARD

Protection of surfaces with paint and varnish. ASSER. *Farbe u. Lack* **1931**, 78.—An address. G. G. SWARD

Criticism of accelerated weathering tests. PAUL NETTMANN. *Farbe u. Lack* 1931, 77.—The usual accelerated weathering test is conducted without proper consideration of the various destructive forces. Until these forces are evaluated, success in accelerated weathering tests will not be attained. G. G. SWARD

Quinquennial review of the mineral production of India for the years 1924 to 1928. Barytes. A. M. HERON. *Records Geol. Survey India* **64**, 324–8(1930). **Mineral paints.** E. H. PASCOE. *Ibid* 409–11.—Red and yellow ocher are the only important mineral pigments in India. ALDEN H. EMERY

Bodied pilchard oils. STANLEY A. LEVY. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. **377**, 139(1931).—Some phys. constants of pilchard oil thickened to various degrees are given. G. G. SWARD

Glass color standards for varnish. STANLEY A. LEVY. *Am Paint & Varnish Mfrs.' Assoc., Circ.* No. **377**, 140(1931); cf. *C. A.* **24**, 4408.—The $K_2Cr_2O_7$ and $NiSO_4$-I_2 values for addnl. intermediate glass color standards are given. G. G. SWARD

Lacquer diluents of the petroleum type. JEFFREY R. STEWART. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. **378**, 143–53(1931).—The kauri-butanol no., the diln. ratio, the soly. in Me_2SO_4 and the aniline point (crit. soln. temp. in aniline) of 27 different lacquer diluents were detd. In most cases the last-named test may be carried out as follows: Warm approx. equal quantities (*viz.*, 3 cc. aniline and 2.5 cc. diluent) in a 6-in. test tube until miscible. Allow the contents of the test tube to cool in a water bath and note the temp. at which the soln. becomes cloudy. Repeat the process twice with 0.3 cc. addns. of diluent each time. The max. temp. at which cloudiness appears is the aniline point. The aniline point is inversely proportional to the other 3 properties. G. G. SWARD

Alcohols for cutting shellac. STANLEY A. LEVY. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. **377**, 137–8(1931).—No differences were noted in the working properties of shellac cut with formula No. 1 and with formula No. 5 alc. contg. alcotate and aldehol. G. G. SWARD

Graphical calculation of the composition of ceramic varnishes. ANGELO CASTIGLIONI. *Industria chimica* **5**, 1351–5(1930).—The quantities of the various constituents in a varnish are represented by the sides of polygons having as many axes as there are constituents, and whose length is proportional to the amts. present. Thus when mixts. of varnishes of known compn. are mixed with those of unknown compn., the compn. of the resulting mix being known, the unknown quantities can be scaled off on the diagram by proportion. A. W. CONTIERI

Yellowing phenomenon in coating compositions. I. Oil vehicles. EDWARD F. MALONEY. **II. Water vehicles.** F. C. ATWOOD. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. **370**, 461–73; *Am. Paint J.* **14**, No. 52D, 25; *Paint, Oil & Chem. Rev.* **90**,

No. 17, 80–3; *Oil, Paint & Drug. Rep.* **118**, No. 19, 54–5(1930).—The theories of yellowing of oil paints are briefly reviewed, 17 references being given. While a slightly elevated temp. accelerates the yellowing of oil vehicles, temps. below 225–50° do not affect water vehicles. Data are given for the hiding power of 15 common pigments in a casein vehicle (compn. not given). Max. hiding power in sq. ft. per gal. of paint was obtained with lithopone which gave 305 sq. ft./gallon. Some of the other values were Titanox-B, 245; Eng. whiting, 163; barytes, 112. The detns. were made on black and white checkered linoleum (cf. *C. A.* **24**, 2312). G. G. SWARD

Surface protection of the light metals. TH. LEIB AND FR. KOLKE. *Korrosion Metallschutz* **7**, 3–11(1931).—This is mostly a discussion of the problems encountered. The use of the Jirotka–Bengough process and of combinations of oil-base and nitrocellulose-base coatings is recommended. Data are given showing the resistance of such coatings against accelerated tests and outdoor exposure. The use of oil-base coatings, applied in 3 thin successive coatings, is recommended. Among the pigments, zinc chromate and iron oxide were found to be the best. Good results were also obtained with zinc white. Expts. were made with the application of oven-drying coatings on untempered lautal, in such a manner that the drying and tempering took place simultaneously. The advantage is that parts treated in this manner can be stored for a longer period of time without danger of corrosion. If such parts are to be exposed to sea water, addnl. protective coatings must be applied. LEOPOLD PESSEL

"Improved" linoleum brush-out test for hiding power. STANLEY A. LEVY. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 377, 135–6(1931).—Results of expts. with a brush-out board (cf. *C. A.* **24**, 2312) whose squares conform in brightness to the specifications of the A. S. T. M. are satisfactory. G. G. SWARD

The nature of the resins in jack pine [*Pinus banksiana*]. HAROLD HIBBERT AND JOHN B. PHILLIPS. *Can. J. Research* **4**, 1–34(1931).—Green and seasoned jack pines have an av. crude resin content of 4.58% and an ether-sol. content of 3.52%. The value of "total acids" present in the resin was the same in each case, but the proportion of "fatty" acids was greater in green wood, while the unsaponifiable matter was considerably less. The seasoned wood contained a lower percentage of fats than the green wood and a correspondingly higher percentage of resin acids. The amt. of unsaponifiable, polymerized terpenic substances was also higher. There was a marked decrease in the amts. of phytosterol and "resene" in the seasoned wood. The isolated resin acids obtained by distn. or esterification contained a high percentage of abietic acid formed by transformation of the original acids. The percentage of natural (pimaric) acids was, however, quite high in the resin acids isolated by petr. ether and recrystd. only twice. A higher percentage of cryst. acids was found in the resin acids from green wood than from seasoned wood, presumably because of the change into amorphous products during storage. The fatty constituents were chiefly members of the unsatd. series, present both as free acids, glycerides, or other esters. The seasoned wood contained much less linolic acid in the glycerides than green wood. Oleic acid was present in about the same proportion in both cases; linolenic was present in only very small quantity. The free fatty acids had practically the same percentage compn. in both green and seasoned wood. The amt. of the total unsatd. fatty acids was higher in the glycerides and free acids from green wood than from seasoned wood. The latter contained a high percentage (30.2%) of oxidized acidic material in the fatty glycerides, indicating that extensive polymerization, or decompn. of some kind, had taken place in the fats present in the green wood during the time of seasoning. The quantities of essential oil obtained from the resins of each kind of wood were very small, amounting to 1.5 to 4.3% of the total crude resins. The products showed no difference in properties, or variation in amt., with time of storage of the wood. Because of the small quantity available for investigation, only α-pinene could be identified. The percentages of phytosterol and resene were extremely small, and were appreciably less in the seasoned wood than in the green wood. The amt. of polymerized terpenic material found in the unsaponifiable matter was much higher in the seasoned wood. This was probably due to extensive polymerization of the essential oil having taken place during the storage of the wood. J. W. SHIPLEY

Preparation of synthetic resins from alkali lignin. MAX PHILLIPS AND HERMAN D. WEIHE. *Ind. Eng. Chem.* **23**, 286–7(1931).—The condensation of lignin with various aromatic amines and with furfural yields sol., dark, fusible resins. Possible uses for the products are suggested. W. A. LA LANDE, JR.

Cr oxide [for use as a pigment] (Brit. pat. 336,671) 18. Asphalt or tar compositions

[for paint] (Fr. pat. 694,789) **20.** Nitrocellulose from wood-pulp board [for varnishes] (Brit. pat. 336,235) **23.** Organic isocolloids [for varnish] (Fr. pat. 694,339) **10.**

Paints. N. V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 694,640, April 28, 1930. The agglomerating agent for colors contg. metals is used in the form of an aq. dispersion. An example is given of the mixt. of Al powder in white spirit which is poured into an aq. dispersion of asphalt and the whole is stirred.

Bituminous paint. CRAIGBANK CHEMICAL CO., LTD., and J. H. TAYLOR. Brit. 336,117, Oct. 26, 1929. A paint comprising bitumen or pitch, a volatile solvent such as turpentine, a pigment or mineral filler such as PbO and a vegetable drying oil such as boiled oil is stated to be improved by the addn. of 5–15% of tannic acid.

"Weather-resistant" paints. I. G. FARBENIND. A.-G. Brit. 336,198, May 2, 1929. Paints such as those formed with the usual drying oils, have incorporated with them such a quantity of a basic pigment such as white lead and minium, as is necessary to combine into soaps all free and combined fatty acids present in the binding agent. Other inert constituents such as colcothar, titanium white, lithopone or blanc fixe may also be added. Examples with details are given. Cf. *C. A.* **25**, 1691.

Anti-rust paint. ADOLF SCHNEIDER. Fr. 694,833, May 1, 1930. Fe or its oxides are heated in the presence of O to 750–1100° for a sufficient length of time to produce the gray highly oxidized compd., which is used in a finely divided state with suitable carriers or binders.

Pigments. TITANIUM PIGMENT CO., INC. Ger. 516,314, Nov. 11, 1926. See Brit. 281,459 (*C. A.* **22**, 3543).

Zinc colors. COMPAGNIE DES MINES, FORGES ET ACIÉRIES DE VITKOVICE and ADOLF ANDZIOL. Fr. 694,290, Apr. 22, 1930. An app. is described for treating pyrites with gases contg. H, for the production of H_2S, which is used for the manuf. of Zn colors from Zn lyes.

Lithopone. SACHTLEBEN A.-G. FÜR BERGBAU UND CHEMISCHE INDUSTRIE. Brit. 336,839, Dec. 5, 1928. For rendering lithopone weather-resisting, it is quenched, after calcination, in water contg. water-sol. sulfates such as $MgSO_4$ or Na_2SO_4, and if the lithopone does not naturally contain some sol. Ba salts a small proportion of a salt such as $BaCl_2$ or Ba sulfide may be added to it before the calcination, so that the sulfate treatment may form $BaSO_4$ around the particles of lithopone. Cf. *C. A.* **25**, 222.

Printing inks and pastes. I. G. FARBENIND. A.-G. Brit. 337,199, Oct. 31, 1929. The process for prepg. printing inks and pastes described in Brit. 307,877 (*C. A.* **24**, 252) is modified by substituting, for the resinous products used, unhardened sol. products produced by the condensation of "polybasic" org. acids with polyhydric alcs. and one or more "monobasic" carboxylic acids contg. at least 7 C atoms, such as the product which may be prepd. by heating together glycerol, linseed oil, phthalic anhydride and colophony dissolved in toluene, which may be ground with Lithol Fast Scarlet R. Various other materials may be added such as sol. cellulose derivs., solvents, plasticizers, driers, etc.

Treating drying oils. GUSTAV RUTH AKT.-GES. and ERICH ASSER. Fr. 694,074, Apr. 17, 1930. Useful products are obtained by heating drying oils, particularly linseed oil or a mixt. of linseed oil and china wood oil, to about 270–280° until polymerization commences. Air is then bubbled through and the heating continued to 310° or more. Cellulose esters or ethers may be added.

Nitrocellulose varnish. KAZUO TAKEMURA (50% to Kazue Oiwa). U. S. 1,791,879, Feb. 10. A coating compn which is especially suitable for use on ironwork comprises nitrocellulose together with mixed solvents and about 3% of $K_4FeC_6N_6$ and pulverized bamboo (suitably about 5%).

Nitrocellulose lacquers, etc. W. J. JENKINS and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 336,615, April 11, 1929. Compns. for the prepn. of enamels or lacquers are made by dissolving water-wet nitrocellulose in a solvent which evaporates in air at normal temps. and has a b. p. not less than about 120° (such as ethylene glycol monoethyl ether or BuOAc) with the addn. of a water-miscible or partly miscible volatile solvent such as industrial alc. or EtOAc in sufficient quantity to keep the water in soln. A solvent of higher b. p. than the main solvent also may be added such as methylcyclohexanone, and water-wet or moist pigments may be added also, as may ingredients such as dammar gum, tricresyl phosphate and the like.

Coloring nitrocellulose lacquers and plastics. I. G. FARBENIND. A.-G. Ger. 516,315, Aug. 29, 1929. Addn. to 515,057 (*C. A.* **25**, 1692). The dyes obtainable from hydrochlorides of dialkylated nitrosoanilines and monoalkylated *m*-aminophenols are used, instead of the dyes specified in Ger. 515,057.

Lacs and varnishes. JOHANNES SCHEIBER. Ger. 513,540, Feb. 21, 1928. Linoleic

acid isomers (octadecadien-9,11-acid-1) obtained from ricinoleic acid are esterified with multivalent alcs., especially glycerol, and the product is used for the manuf. of lacs and varnishes. Resin may be added. Thus, technical ricinoleic acid is heated to 200° and distd. *in vacuo*. The product going over at 260–270° is heated to 200° with glycerol to give a bright oil. Other examples are given. Cf. *C. A.* 25, 1400.

Coating composition. VICTOR H. TURKINGTON (to Bakelite Corp.). Can. 308,848, Feb. 24, 1931. Resinous compns. are prepd. by reaction of 100 parts of cresol, 200 parts of tung oil and 25 parts of $(CH_2)_6N_4$ at a temp. of 190–200°. Cf. *C. A.* 25, 834.

Coating compositions containing *m*-styrene and softeners. WALTER E. LAWSON (to E. I. du Pont de Nemours & Co.). U. S. 1,792,102, Feb. 10. Compns. suitable for coating metals, glass, wood, etc., comprise *m*-styrene and tricresyl phosphate, dibutyl phthalate, dixylyl ethane, glyceryl dibenzyl ether, butyl stearate or homologs of these compds. Cf. *C. A.* 24, 980.

Coating metals with synthetic resins. HEROLD A.-G. Brit. 337,192, April 30, 1929. Solns. of phenol-aldehyde artificial resins are applied to metal surfaces while the latter are at a temp. above the b. p. of the solvent (which may be "spirit") to evap. the solvent and the coatings are hardened by heating. The rate of hardening may be restricted by the use of incomplete condensation products or by dilg. the coating soln. with cresols, glycerol, glycol or high b. p. polyglycols, or addn. of solids such as feldspar, zirconia or kieselguhr.

Purifying and decolorizing rosins. ROBERT C. PALMER and CLYDE O. HENKE (to Newport Co.). U. S. 1,791,633, Feb. 10. Rosin dissolved in a volatile hydrocarbon material such as petroleum naphtha is treated with resorcinol at a temp. (suitably about 90–110°) at which the resorcinol is in liquid form and below the b. p. of the hydrocarbon material, and, after agitation, the materials are allowed to stand and the liquid resorcinol layer contg. the impurities is removed. Cf. *C. A.* 25, 424.

Rosin decolorization and purification. DURAIN C. BUTTS (to Hercules Powder Co.). U. S. 1,791,658, Feb. 10. Rosin is heated in an inert atm. such as CO_2 to a temp substantially within the range of 280° to 350° while avoiding substantial decompn. or distn.

Inlaid linoleum. W. O. L'ESTRANGE. Brit. 336,277, July 8, 1929. Mech features.

Condensation products from vinyl esters. I. G. FARBENIND. A.-G. Brit. 336,237, Nov. 16, 1928. In the production of polymerization products such as those of vinyl acetate, chloroacetate, chloride and benzoate and of lacquers from the resinous derivs thus obtained, there is added (before, during or after the polymerization) a small proportion of a basic substance sol. in org. solvents such as guanidine or its derivs., hydrazine or its derivs., ethylamine, formaldehyde or phenylhydrazones, and N compds. having plasticizing properties (such as a condensation product of urea and formaldehyde) also may be added. Benzoyl peroxide also is added in polymerizing vinyl benzoate. The production of *lacquers* is described. Cf. *C. A.* 25, 389.

Molded articles from synthetic resin compositions. BAKELITE CORP. Brit. 336,265, July 10, 1929. Articles with a raised surface design are made by applying a colored mixt. (such as a plastic phenol resin and bronze or other pigment) to a phenol resin compn. in a partially cured state and then completing the curing. Various details of procedure are described.

Colored molding mixture containing a synthetic resin. BAKELITE CORP. Brit. 336,264, July 10, 1929. A mixt. comprising a potentially reactive resin, a filler such as wood flour and a pigment is subjected to extrusion whereby the colored particles are distributed along definite flow lines.

Molding articles of artificial resin. HEROLD A.-G. Brit. 337,184, Oct. 24, 1928. Articles of artificial resin such as balls, tubes or dishes are cast by the use of a cast mold of Pb or other easily fusible metal within an outer mold which may be made by either casting or dipping. Various structural details are described.

Modifying resins, waxes and fatty oils. HERBERT HÖNEL. Austrian 120,679, May 15, 1930. Resins, waxes and fatty oils are heated with a subordinate amt. of a primary condensation product obtained under alk. conditions from CH_2O and a phenol having a hydrocarbon substituent in the *p*-position to the OH group. In this way, the resins and waxes are rendered harder and of higher m. p., and fatty oils are made more viscous. Thus, an oily condensation product from *p*-amylphenol and CH_2O may be introduced into 5 times its wt. of a fused coumarone resin m. 50–55°, the temp. being gradually raised to 200°; a clear resin m. 70–75° is obtained. Other examples and addnl. details are given.

Synthetic resins. IMPERIAL CHEMICAL INDUSTRIES, LTD., and R. HILL. Brit.

336,698, Aug. 3, 1929. Blending of monohydroxylated fatty oils such as drying oils with resins such as those formed from glycerol and phthalic anhydride or similar components is facilitated by replacing some or all of the polyhydric alc. by a reaction product of a polyhydric alc. with a lower aliphatic aldehyde such as CH_2O; *e. g.*, glycerol and polymerized CH_2O are condensed together, then phthalic anhydride and tung oil or linseed oil, or phthalic anhydride, tung oil, colophony and glycerol are added and the mixt. is heated until a homogeneous resin is produced. Varnishes prepd. from such products dry rapidly in the air or when heated and their drying may be facilitated by adding substances such as Co linoleate.

Synthetic resins. BAKELITE CORP. Fr. 694,047, April 16, 1930. White masses of compns. having a basis of phenol resinoid are made by the reaction of phenol about 100 with CH_2O about 200 and di-Et phthalate 70 parts in the presence of oxalic acid acting as catalyst. Water is removed from the reaction mass, a volatile solvent is added and the whole mixed with "albalith." The liquid mixt. thus obtained is applied to a filling material. The app. used must not contain Fe or Cu. Cf. *C. A.* **25**, 1400.

Synthetic resins. EDGARD ISRAEL. Fr. 695,036, Aug. 7, 1929. Urea and CH_2O are condensed with glucose or lactose as condensing agent, in the presence of a metallic oxide, preferably ZnO, and polymerized at 80°.

Artificial resins of the glycerol phthalic anhydride type. BAKELITE CORP. Brit. 336,645, July 10, 1929. A "polybasic" acid such as phthalic anhydride or succinic acid and a polyhydric alc. such as glycerol are heated together until "slag formation" begins and the reaction is then arrested by rapidly cooling the mass throughout so that transformation to a "slag condition" is prevented (as by casting in thin layers). The product may subsequently be baked for hardening or may be broken up, remelted and cast. Dyes may be added and various details of temps. employed, etc., are given.

Artificial resins. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 694,669, Apr. 29, 1930. Artificial resins are prepd. by the reaction of amines such as $PhNH_2$ with insufficient aldehyde, then adding more aldehyde and heating under pressure to cause the resin to pass to the infusible state.

Artificial resins. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 694,181, April 18, 1930. Rapidly hardening resins are made by the union of a polybasic acid-polyhydric alc. resin with a condensation product of CH_2O and urea or thiourea or with substances capable of giving a product of this kind, this union being effected in an alc. solvent and with the aid of heat. As solvents ethylene chlorohydrin, BuOH or hexahydrophenol may be used. Cf. *C. A.* **24**, 740.

Artificial resins. LOUIS C. F. PÉCHIN. Fr. 694,978, May 5, 1930. Artificial phenol-aldehyde resins are hardened by heating them under vacuum to 95–105° in vessels placed in an oil of low d., and then to 140–180° under atm. pressure still in the oil. Cf. *C. A.* **25**, 1692.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Determination of the fat content of oil seeds. M. MONHAUPT. *Chem.-Ztg.* **55**, 70(1931).—M. modifies Dopfer's method for the detn. of fat in oil seeds as follows: place 4 g. of the ground seed in a round-bottom, heavy glass bottle together with 40 cc. of gasoline b. 40–60°, 10–12 g. of sand and 5 or 6 steel balls of 10–12 mm. diam. and grind in a shaking machine for 1–2 hrs. or until apparently "dust-free"; allow to settle, evap. 20 cc. of the gasoline ext., weigh and calc. the % of fat according to the formula: $x = (100 \times 40 \times f)/4(20-1.0753f)$, in which f is the wt. of the oil residue from 20 cc. gasoline soln., and 1.0753 is the sp. gr. factor for oil (1.00/0.93). P. ESCHER

The determination of unsaturation of fats and acids. III. Wijs iodine number. J. VAN LOON. *Chem. Umschau Fette, Oele, Wachse u. Harze* **37**, 257–62(1930); cf. *C. A.* **24**, 3663.—The Wijs method for detn. of I no. shows the theoretically true unsatn. value when correct exptl. conditions are selected, except with triple bonds which become only ½ satd. by halogens. There is no substitution by I even in prolonged action of the reagent. For official analyses the I no. of the acids (after removal of the unsapon. matter) should be detd. in addn. to that of the oil, because their I no. is more const. than that of the oil. If the total acids show an I no. which increases on continued action of the reagent, a polymerized product or some unknown acid may be present. The Wijs method satisfies all scientific requirements and is applicable to general fat chemistry. P. ESCHER

Some physical constants of fatty acids. (Specific heat, viscosity, absorption of

ultra-violet light.) E. L. LEDERER. *Allgem. Öl- u. Fettztg.* **27**, 237–41(1930).—The sp. heats of stearic, lauric and oleic acids were measured at several temps. and calcd. for others. A new formula for calcn. of viscosity, based on thermodynamic principles, is derived: $\log n = (q°/4.571\ T) - 2.75 \log T + ET + C$, where n = coeff. of viscosity (in poises), T = temp., $q°$ = heat of assocn. at 0° (cal. per mol.), E = const., C = const. The values of $q°$, E and C for the following substances are, resp., butyric acid 1960, 0.001770, 2.9952; valeric acid 2330, 0.001663, 2.9050; caproic acid 2740, 0.001401, 2.8200; heptylic acid 3210, 0.001470, 2.5791; caprylic acid 3475, 0.001576, 2.4883; nonylic acid 3655, 0.001696, 2.4160; capric acid 3700, 0.001992, 2.3865; myristic acid 5030, 0.001670, 2.0221; stearic acid 5490, 0.001907, 1.7920; pentane 724, 0.002097, 3.0077; water 5825, 0.008222, —1.9613. The values of n for butyric acid at 8 temps. between 0° and 160° were calcd. and found to agree within 2.2% with the values given in the tables of Landolt-Börnstein. Measurements of the absorption of ultra-violet light were made on the satd. fatty acids in the liquid state, rather than in soln. In making the measurements a photoelec. Na cell was used instead of a photographic plate. In this way it was possible to make more accurate measurements than heretofore. It was found that all the fatty acids observed showed sp. absorptions of the wave lengths between 270 and 280 mμ. This sp. absorption was observed in synthetically prepd., as well as in naturally occurring, fatty acids but not in triglycerides. It was further observed that the sp. absorption for the shorter chain acids was for the shorter wave lengths. Thus the sp. absorption range was between 270 mμ for propionic acid, and 280 mμ for stearic acid. The cause for this sp. absorption has not yet been definitely established. W. F. BOLLENS

Method for estimation of total unsaturated fatty acids of higher unsaturation than oleic acid in fats and oils. N. BASKIN. *Allgem. Öl- u. Fettztg.* **27**, 243–4(1930).—The method is based on the conversion of unsatd. fatty acids of high mol. wt. into ether acids (cf. *C. A.* **24**, 2142). The sapond. fat carrying excess alkali of 0.1% is polymerized in an atm. of H_2 for 2–3 hrs. at a temp. of 290°. This procedure reduces the unsatn. of those fatty acids contg. more than 1 double bond to that of oleic acid. The difference in I nos. of the sepd. fatty acids before and after polymerization is called the "Mutit" no. and is a measure of the fatty acids contg. more than 1 double bond. The "Mutit" no. of several oils is given: olein (tech.) 1.2, peanut oil 23, cottonseed oil 50, soy-bean oil 50, sunflower-seed oil 46, linseed oil 90, herring oil 54, cod-liver oil 74.1. W. F. BOLLENS

Characteristic fatty acids of vegetable and animal fats with reference to the biological families in which they occur. T. P. HILDITCH. *Allgem. Öl- Fettztg.* **27**, 219–22, 255–8 (1930); cf. *C. A.* **24**, 4176.—A compilation is made of the percentage fatty acid compn. of a large no. of fats and oils arranged according to the biological families in which they occur. W. F. BOLLENS

Manipulation and evaluation of the Mackey test. KEHREN. *Seifensieder-Ztg.* **58**, 29–32(1931).—K. summarizes former exptl. results as follows: The real cause of the temp. increase in the Mackey test is the rapid oxidation of the linolic or linolenic acid when present in the olein to be tested. This temp. increase is accelerated by iron soaps or other pos. catalysts and is inhibited by neg. catalysts like β-naphthol. The presence of soaps should be confirmed by an ash detn. (upper limit less than 0.07%) and by a qual. test for Fe. When present, the temp. test should be repeated after removing the Fe soap from the sample by extn. with dil. HCl. The I no. and Kaufmann's thiocyanate no. should be detd. to detect any presence of linolic acid if a neg. catalyst is suspected. The presence of much unsaponifiable matter also reduces or retards the temp. increase. The standard limit of 100° or 150° after 1 hr. should be modified, since oleins which contain acids with more than 1 double bond show a rapid temp. increase after ¾ hr., the cotton being more or less carbonized. Directions for making the test are given in much detail. P. ESCHER

Further notes on the Mackey test. H. WOLF AND R. HEILINGÖTTER. *Chem. Umschau Fette, Oele, Wachse u. Harze* **38**, 24–5(1931); cf. *C. A.* **25**, 429.—The selection of the material for the cotton-bearing cylinder may well be left to the (German) Olein Commission. The samples of olein should be tested in the same condition as received; it would be illogical to attribute the temp. rise due to the presence of any soap to the presence of "unsatd. fatty acids" in an otherwise unobjectionable sample. The soaps cause a temp. rise only after prolonged (1.5 hrs.) heating at 100°, while unsatd. acids usually show a temp. rise at a low temp. after ¾ hr. An olein becomes a fire hazard through the presence of unsatd. acids, not by the presence of soaps. The present tendency is to reduce the time of heating to 1 hr. rather than to increase it to 3 hrs. The moment the thermometer in the cotton registers 70° should be considered the start-

ing time of heating. It is not necessary to pass a stream of air through the app., since the natural ventilation through the tubes is sufficient. P. ESCHER

The pyrolysis of vegetable oils of high acetyl value. RAYMOND DELABY AND RAYMOND CHARONNAT. *Bull. sci. pharmacol.* **38**, 17–23(1931). A. E. MEYER

Yield differences in the oil mill. E. I. BETTER. *Chem. Umschau Fette, Oele, Wachse u. Harze* **38**, 33–4(1931).—B. calls attention to unaccounted for differences (about 1%) in the oil mill between the calcd. yield based on lab. analysis and the actual yield in the factory. It is suggested that this difference is due to phosphatides or lipoids showing different solubilities under lab. and factory conditions. P. ESCHER

Analysis of refined (olive) oils. GAETANO MAROGNA. *Atti III congresso naz. chim. pura applicata* **1930**, 564–8.—From chem. and phys. tests of a great many samples of olive oil it is concluded that refined oil from the first extn. acts like a true olive oil as regards chem. and phys. consts. and various analytical tests; the exceptions are the Wood light test and the Bellier test. Oils from the second extn. show a reduction in av. quality and chem. and phys. tests. The characteristics of edible olive oil should be standardized strictly. Oils which have a n above 62 8, a thermal index above 47, unsaponifiable content above 1.5%, and which do not correspond to the Bellier, Blarez and Fachini-Morawsky tests should be excluded. Addn. of refined, first-extn. olive oil should be limited, so as not to vary these tests. E. M. SYMMES

Correlation of oil content to presence of color in the stem of castor (Ricinus communis). G. B. PATVARDHAN. *Poona Agr. Coll. Mag.* **22**, 16–8(1930).—In 32 samples of beans from red-stemmed castor plants the oil content ranged from 40.45 to 54.97% with an av. of 45.94%, while in 24 samples from green-stemmed plants the oil content ranged from 35.75 to 54.24% with an av. of 51.22%. The analyses were made on seed of parents which had proved true to stem color in the succeeding generations. K. D. JACOB

Detection of castor oil and peanut oil in abrasin oil. HANS WOLFF AND J. RABINOWICZ. *Farben-Ztg.* **36**, 596–7(1930).—Castor oil can be detected by the formation of octyl alc. on fusion with KOH. The amt. can be calcd. from the acetyl values of the sample and of an EtOH (80–85%) ext. Peanut oil can be detected by the formation of arachidic acid and detd. by means of its n, which is 1.468–72; that of abrasin oil is 1.517. G. G. SWARD

Suggestions for the proposed unified methods of analysis of Turkey-red oil and similar products. WIZÖFF. *Chem. Umschau Fette, Oele, Wachse u. Harze* **38**, 34–7 (1931).—This is the text for the proposed standard methods of analysis as worked out by the German Commission for Fat Analysis jointly with the Intern. Soc. of Leather Chemists, the National Comm. of Trade Specifications and the Union of Turkish Red Oil Mfrs. The methods are based on extensive analytical investigations and on control checks by public analysts, but cover only sulfonated oils whose SO_3 can be completely split off by boiling HCl. P. ESCHER

Constituents of the leaves of pine (Pinus Thumbergii). I. JENJIRO SAKURAI. *J. Pharm. Soc. Japan* **51**, 34–9(1931).—S. isolated from the petr. ether ext. of the leaves of pine a wax-like substance (I) which had the following phys. properties: d^{17} 0.9201, m. 78–80°, acid no. 29.84, sapon. no. 218.90, ester no. 189.06, sapon. no. after acetylation 219.18, and I no. 7.55. Sapon. of I (100 g.) gave mixed solid fatty acids (II) (85 g.). II was esterified and fractionated into the following constituents: lauric, palmitic, stearic, hydroxypalmitic acids. F I. NAKAMURA

Textile soap. G. T. HALBERSTADT. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 67–70; *Am. Dyestuff Reptr.* **20**, 109–12(1931).—A review. M. H.

Lime-proof soaps. W. SCHRAUTH. *Seifensieder-Ztg.* **58**, 61–3(1931).—The usual lime-proof soaps are the Na salts of sulfonated fatty acids which keep the Ca soaps, formed by hard water, in such a finely divided state that they are not deposited upon the fabric of the washed goods. S. describes a new type of soap-like salts made by reducing the higher fatty acids to their alcs., sulfonating them and converting the sulfonates into their Na salts of the general formula RCH_2SO_3Na. These salts have the properties of soaps, excelling in emulsifying power; lauric Na sulfate shows with Traube's surface tension pipet 29 drops in spindle oil against 17 drops for regular coconut-oil soap. They are not easily hydrolyzed and are very stable toward Ca and Mg salts. P. ESCHER

Rancidity of soaps and its relation to the properties of fats. F. WITTKA. *Seifensieder-Ztg.* **58**, 3–5(1931); cf. *C. A.* **25**, 613.—W. prepd. soaps from various fats and examd. their keeping quality toward oxidation in the presence and absence of catalysts and light. Of the hardened fish oils whale oil resists oxidation most, herring oil is equiv. to edible tallow, sardine oil turns brown on exposure to light or to catalysts; the latter

2 oils on standing take on an intense odor of hardened oil; peanut, sesame and palm-oil are sensitive to air and light. Coconut oil and its soap keep longest; soaps from palm-kernel oil and Babassu fat do not keep quite as well. Soaps from corn, grape-kernel and linseed oil soon turn rancid even without catalysts. Soaps with 15% or less of WW or FG rosin show little change, but larger quantities make them unstable and sticky.
P. ESCHER

Moisture determination in soaps and fats by distillation. E. SCHLENKER. *Seifensieder-Ztg.* **58**, 96–7(1931).—From lab. expts. S. concludes that H_2O detns. in soaps by the distn. method with petr. benzine yield low results, unless a sufficient amt. of olein (20 g. per 30 g. soap flakes) has been added before distn.; addn. of dry sand is superfluous. Butter needs no olein addn., and correct results are obtained by direct distn. with petr. benzine. S. prefers xylene in place of petr. benzine, since the latter holds some of the distd. H_2O in min. suspension. P. ESCHER

Indirect estimation of potassium and sodium in filled potassium-sodium soaps. G. KNIGGE. *Allgem. Öl- u. Fettztg.* **27**, 223–5(1930).—The indirect method of Davidsohn (*C. A.* **24**, 3669) is proved with a soap of known compn. Ground pumice is used as the filler. The results check very well with known compn. and also with results obtained by the perchlorate method. W. F. BOLLENS

Surface tension of alkaline soap solution. SUTEZO OGURI. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 471–4(1930).—A modified Millard's app. was used to det. surface tension by the drop-wt. method. All measurements were made at 40°, and the tip of the pipet had a radius of 3.23 mm. The surface tension was calcd. from Tate's law $2\pi r\gamma = mg$, in which $2\pi r$ = the circumference of the tip, γ = surface tension, m = effective mass of the drop, and g the acceleration due to gravity. One table and 3 graphs are given. E. SCHERUBEL

The effect of cleansing agents on linen and cotton (SIMOLA) **25.** Determination of vegetable oils in butter (DE SOUZA VIEIRA) **12.** Structure of synthetic mixed triglycerides (BHATTACHARYA, HILDITCH) **10.** Apparatus for extracting gases from oils (Fr. pat. 693,985) **1.** Fractional condensation of oil vapors (Ger. pat. 513,613) **22.** Residue of sulfonic acids from oil-refining [fat-splitting agents] (Fr. pat. 694,236) **18.** Modifying waxes and fatty oils (Austrian pat. 120,679) **26.** Continuous production of dispersions of waxes (U. S. pat. 1,792,067) **22.**

Extracting oils and fats. C. SCHLOTTERHOSE and H. BRANDT (trading as Schlotterhose & Co.). Brit. 337,079, March 28, 1929. The extn. process described in Brit. 316,881 (*C. A.* **24**, 2002) is modified by subjecting the material to be extd. to a treatment with the vapor of the solvent, in direct or countercurrent, in addn. to or instead of treatment with liquid solvent. Various details of app. and procedure are described.

Extraction of oil, etc., from soy beans. M. SATO and C. ITO. Brit. 336,273, June 10, 1929. Extn. with a solvent such as EtOH is effected at a temp. above the b. p. of the solvent but below 120° (suitably at about 85°), and the soln. of fatty oil is drawn off and cooled to below 50° to sep. oil and obtain a liquid residue contg. coloring matter, sugar and lecithin. Brit. 336,274 (M. Sato and Y. Ishida) describes the extn. of soy beans and the like with a solvent such as alc. admixed with benzine or benzene of such concn. and quantity that the water in the resulting liquor is less than 10%. Extn. is effected above 65° and oil is sepd. by cooling. An arrangement of app. is described.

Extracting oleaginous materials with solvents such as in degreasing bones. JOSEPH SAVAGE. U. S. 1,791,906, Feb. 10. A volatile hydrocarbon solvent is circulated in a closed circuit through an extn. chamber, passing through the chamber as vapor, under superatm. pressure; the vapors are condensed, extd. water is automatically sepd., and hot sepd. solvent is returned to the circuit at a temp. near the b. p. of the solvent at the pressure existing in the circuit. App. is described.

Glycerol distillation. I. G. FARBENIND. A.-G. Brit. 336,608, July 12, 1929. Crude glycerol is treated, at its b. p. under the reduced pressure employed (suitably 20 mm. or 30 mm.) with finely divided liquids (such as wet steam or a mist of CCl_4 or benzine assocd. with air or CO_2) inert to glycerol and having a b. p. not exceeding that of water and assocd. with gaseous or vaporous carriers (the operation being continuous). Various details and examples are given.

Stabilizing fatty substances and soaps. R. T. VANDERBILT CO., INC. Fr. 694,286, Apr. 22, 1930. Fatty substances and soaps are stabilized by the addn. of a phenolate prepd. by the reaction of a phenylphenol such as 2- or 4-hydroxybiphenyl with a base which is itself a stabilizer such as diphenylguanidine, triethanolamine or an alkylene-

diaryldiamine. If the fatty substance or soap is animal or vegetable a *p*-phenylphenol is used, if mineral an *o*-phenylphenol is used. Cf. *C. A.* **25**, 430.

Soaps. A. IMHAUSEN. Brit. 335,954, May 6, 1929. Soaps of high lathering power comprise grain soap and coconut oil or palm-kernel oil paste soap contg. little salting-out agent. Various details of manuf. are given.

Soap. ALBERT A. BESNARD. Fr. 695,028, Aug. 6, 1929. A soap which cleans the hands without water contains agar-agar 2, psillium 3, glycerol 50, Na_2CO_3 50, black soap in pulp 50, "NH_3" 25, Javel water 5 and distd. water 815 parts.

Soap. CARLOS CONEN. Fr. 694,220, April 19, 1930. A soap is made by adding naphtha benzine or refined petroleum to a fatty acid and adding an alk. substance such as Na_2CO_3 in the dry state.

28—SUGAR, STARCH AND GUMS

J. K. DALE

Defecation of cane sugar juices. NATHAN LEVY W. *Bull. assoc. chim. sucr. dist.* **47**, 502–3(1930); cf. *C. A.* **4**, 3310.—The author reviews his method for detg. the right amt. of lime for defecation of cane juices. F. CAMPS-CAMPINS

The use of lime and sulfurous acid in the defecation of sugar juices. NATHAN LEVY W. *Bull. assoc. chim. sucr. dist.* **47**, 500–2(1930).—The harmful effects of too much or too little lime in the defecation of cane sugar juices are reviewed. If excess lime is added and then followed by SO_2 to neutrality, all the evil effects of excess lime are produced and the subsequent SO_2 does not destroy them. The author advocates sulfitation before, instead of after, liming. A slight excess of SO_2 is not harmful; the right amt. of lime, as detd. on raw juice, is then added. There will be no deleterious result even though the resultant juice is slightly acid. F. CAMPS-CAMPINS

Advances in beet-sugar manufacture in 1930. EDMUND O. VON LIPPMANN. *Chem.-Ztg.* **55**, No. 17, *Fortschrittsber.* No. 1, 33–6(1931). E. H.

The "Werkspoor" rapid crystallizer. R. BONATH. *Intern. Sugar J.* **32**, 306–9 (1930).—The earlier method of operating crystallizers was in series, utilizing the surrounding air for cooling. Further developments were made with cooling jackets, and later fixed internal tube systems were adopted. A more successful type was developed by Lafeuille, who introduced a fixed tubular system, around which the hermetically closed cylinder contg. the massecuite rotated. The requirements of a crystallizer are (1) shortening the period of fermentation, (2) avoidance of formation of false grain, (3) simple and substantial design. The "Werkspoor" crystallizer consists of a trough which may be either U- or bottle-shaped. The revolving water-cooled stirring system consists of a hollow drum, of large section, riveted to which are a number of semicircular hollow cooling pockets coupled by suitable pipe connections inside the central drum. The transport of the massecuite from one end to the other of the crystallizer is effected by a screw-shaped element placed outside and independent of the cooling pockets. W. L. OWEN

Starches and the constitution of starch. ST. V. NÁRAY-SZABÓ. *Z. physik. Chem.*, Abt. A, **151**, 420–4(1930); cf. *C. A.* **25**, 16.—A discussion of recent work. W. L. HILL

The effect of plowing-under cane trash upon the available N of the soil (OWEN, DENSON) **15**. Potash fertilizers at the "Belle Etoile" distillery (DUBOSC) **15**. An inexpensive crystal or molasses separator (KING) **1**. Sugar anhydrides (MICHEEL, MICHEEL) **10**. N-containing sugars (BERTHO, *et al.*) **10**. Continuous production of dispersions of gums (U. S. pat. 1,792,067) **22**. Extracting [sugar from beet roots] (Fr. pat. 694,602) **17**.

Device for cleaning sugar canes. RALPH S. FALKINER. Ger. 513,928, Mar. 2, 1929.

Apparatus for storing sugar beet in water without loss of sugar. FIRMA R. FÖLSCHE. Ger. 513,927, Dec. 10, 1929.

Apparatus for mixing liquids with solids, particularly for liming sugar juices. GILCHRIST CO. Ger. 516,359, July 19, 1925. Brit. 247,541 (*C. A.* **21**, 668).

Refining sugar. RAFFINERIE TIRLEMONTOISE, SOC. ANON. Ger. 516,360, Oct. 1, 1926. See Brit. 278,302 (*C. A.* **22**, 2680).

Carbohydrate derivatives. I. G. FARBENIND. A.-G. Fr. 694,696, April 30, 1930. Carbohydrate derivs. which are sol. in water and org. solvents and which are useful

for the prepn. of films, lacquers, artificial silk, plastic substances, swelling and impregnating agents, etc., are made by treating a carbohydrate or one of its derivs. with an alkylene oxide or one of its homologs or analogs in the presence of an aq. alkali. Examples are given of the treatment of potato starch, dextrin or cotton with ethylene oxide, propylene oxide, etc.

Dextrose. CORN PRODUCTS REFINING CO. Ger. 513,570, July 22, 1923. Anhyd. dextrose is prepd. from converted starch solns. by crystn. at 57–49°. The crystals are sepd. from the mother sap by centrifuge. Cf. *C. A.* **24**, 4652.

Soluble starch. ROBERT HAAKE and WALTER HAAKE. U. S. 1,792,088, Feb. 10. A highly concd. oxidizing liquid such as NaOCl soln. is added in small quantities to the starch to be disintegrated and mixed with it while maintaining the starch in its powdery condition, thus elevating the heat of reaction to such an extent that the chem. transformation is performed without any residue and a sufficient evapn. is effected of the slight surplus of moisture contained in the treating soln. added.

Starch products. INTERNATIONAL PATENTS DEVELOPMENT CO. Ger. 516,361, July 3, 1928. See Brit. 294,979 (*C. A.* **23**, 2065).

29—LEATHER AND GLUE

ALLEN ROGERS

Tannery effluent. I. Effect of various gases on the nitrogen distribution. EDWIN R. THEIS AND PHILIP KRATZ. *Ind. Eng. Chem.* **23**, 69–71(1931).—The effect of p_H value on evolution of gases from soak waters contg. $NaNO_3$ was that gases were evolved at p_H values 1 to 5, and absorbed at higher p_H values. Bubbling O_2 through soak water promotes formation of NH_3, indicating deaminization; it causes the effluent to become very colloidal in character and retards the formation of volatile sulfides. H_2 furthers the formation of H_2S, causes deaminization with subsequent reduction, and finally causes the formation of volatile acids. H. B. MERRILL

Fat-liquoring of chrome leather. Effect of hydrogen-ion concentrations on oil adsorption. EDWIN R. THEIS AND FRANK S. HUNT. *Ind. Eng. Chem.* **23**, 50–3(1931).—The amt. of oil taken up by chrome leather is studied for numerous mixts. of sulfonated and raw oils and com. fat liquors, as a function of the p_H value of both the skin and the fat liquor. Characteristic curves are obtained for each oil mixt. employed. Relation of the strength of the leather to the kind of fat liquor and to the amt. of oil adsorbed is shown. The adsorption of oil is shown as "oilation" by means of the dilatometer. H. B. MERRILL

A note on the cause of certain red colorations on salted hides and a comparison of the growth and survival of halophilic or salt-loving organisms and some ordinary organisms of dirt and putrefaction on media of varying salt concentrations. MADGE E. ROBERTSON. *J. Hyg.* **31**, 84–95(1931).—Certain brick-red stains on salted hides are produced by the growth of halophilic organisms which come from marine salt used in curing the hides. There are many varieties of these organisms which flourish best in high concns. of salt and fail to grow below 6%. The organisms of dirt and putrefaction, though certain of them survived as high a concn. as 30% for a considerable time, failed to multiply above 8%. The non-halophilic cocci survived at high salt concns. much longer than the non-halophilic bacilli. JOHN T. MYERS

Glue making from chrome-leather scrap by the chromic hydroxide process. C. STIEPEL. *Chem.-Ztg.* **54**, 894 5(1930).—In this process the chrome complex in the leather is changed to a stable, non-tanning hydroxide by "intensive liming." The process is similar to the magnesia process, but the yields obtained with the latter are inferior. The process is far superior to the various acid processes, is economical as regards time, labor and equipment, and yields a glue of good quality. H. B. M.

Protecting leather from fungi (Brit. pat. 336,244) **18.**

Treating hides with liquids for tanning, etc. CHARLES WESLEY NANCE. Ger. 513,929, Dec. 31, 1927. See Brit. 310,823 (*C. A.* **24**, 748).

Treatment of skins before tanning. DAVID L. LEVY. Fr. 694,407, April 24, 1930. Skins are treated with a soln. of mineral or org. acids and alkali, alk. earth or metallic salts before the usual tanning operation. Cf. *C. A.* **24**, 1247.

Tanning agents. I. G. FARBENIND. A.-G. Fr. 694,257, April 22, 1930. Condensation products which are sol. in water and have very pronounced tanning and charg-

ing properties are prepd. by the reaction of urea, its homologs or substitution products and aliphatic aldehydes on di- or poly-hydric phenols of the C_6H_6 series, their homologs or substitution products, preferably in the presence of acid condensing agents. Part of the phenols may be replaced by tanning substances of vegetable origin. Several examples are given. Cf. *C. A.* **25**, 1116.

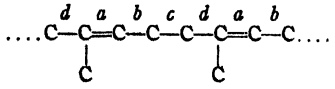
Tanning compositions. W. SAILER. Brit. 336,984, April 18, 1929. Sulfite cellulose lye, phenols, cresols and natural tanning substances such as a bark ext. are caused to react with enzymes such as phenolases, peroxyidases or dehidrases and with substances yielding O such as H_2O_2 or perborates. The products may be further treated with halogens and are suitable for use preliminary to chrome tanning

Greasing leather. HERMANN BOLLMANN and BRUNO REWALD. Ger. 516,187, Sept. 7, 1927, 516,188, Oct. 25, 1927, and 516,189, Dec. 25, 1927. Addns. to 514,399 (*C. A.* 1704). There is used (1) a mixt. of lecithin and train oil emulsified in a relatively large amt. of water (516,187), or (2) an aq. soln. of lecithin (516,188) or (3) a mixt. or emulsion of lecithin and fatty oil with a small quantity of soap or sulfonated oil, with or without a small quantity of mineral oil (516,189).

Dyeing leather. I. G. FARBENIND. A.-G. (Bartholomäus Vossen, inventor). Ger. 513,842, Feb. 4, 1925. Leather is dyed by acid azo dyes built up by the process amine ⟶ 1-amino-8-hydroxynaphthalene-3,6-disulfonic acid ⟶ resorcinol ⟶ *p*-nitraniline, the amine indicating sulfanilic, picramic or naphthionic acids. The example describes the dyeing of deacidified chrome leather by the dye built up from picramic acid.

Machine for mordanting hides. VEREINIGTE HUTSTOFFWERKE BLOCH & HIRSCH, C. F. DONNER G. M. B. H. Ger. 513,698, Mar. 23, 1929.

Coated fabric [imitation leather]. ARTHUR W. BURWELL (to Alox Chemical Corp.). U. S 1,791,711, Feb. 10. A coating compn. suitable for use in the manuf of "artificial leather" comprises nitrocellulose and a softening agent consisting essentially of the water-insol., satd. aliphatic, high mol. wt., carboxylic acid product obtainable by contacting a free-O-contg. gas such as air with a petroleum hydrocarbon mixt. consisting of a 48 43° Bé. petroleum distillate in the liquid state, in the presence of an "oxidation exciter" such as Mn oleate at a reactive temp. not above about 155° (suitably about 140°) and at a superatm. pressure but not greater than about 350 lb. per sq. in., to the point of incipient formation of petroleum-insol. compds. in the mixt. An app. is described suitable for oxidation of the petroleum distillate.



30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The oil and the lipase-like enzyme in Para rubber seed. YOSHITORA IWAMOTO. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 409–11(1930).—Fallen seeds from Malaya were used in the expts. The following data give the kind of seed, the grade of oil from each kind, the color of the oil, its taste and its acid no., resp.: fresh with yellow-white kernel, 1st, faint yellow, sweet, 7.21; older with dirty yellow kernel, 2nd, yellow, bitter, 24.71; partly putrefied, 3rd, brownish yellow, bitter, 77.10; badly putrefied with dark gray kernel, 4th, brown, very bitter, 110.86. The results show that fresh seeds are suitable for practical oil extn. Oil obtained by cold-pressing is superior to oil by hot-pressing, as shown by a higher yield, a lighter color, a sweeter taste and a much lower acid no. (19.70 *vs.* 45.22). A bitter taste is best removed by NaOH. Oil extd. with petr. ether from fresh seeds showed d_4^{15} 0.9234, n_{20} 1.4757, acid no. 7.12, I no. 138.8, solidifying point 2°, sapon. no. 189.20, Reichert-Meissel no. 2.28, acetyl no. 2.41, unsapoñiable matter 1.62, insol. hexabromide (fatty acids) 15.48. By the Pb salt-Et_2O method, the fatty acids yielded 79.99% of yellow liquid acids and 17.81% of white solid acids. The former when oxidized with alk. $KMnO_4$ by the Hazura method gave dihydroxystearic, sativic and linusic acids. This shows that the liquid acids contain considerable oleic, linolic and linolenic acids. After recrystn. from 95% EtOH at —20°, the solid acids yielded a white cryst. powder which m. 62° and had a neutralization no. 204.62, which was probably a mixt. of 70% stearic acid and 30% palmitic acid. The high acid no. of the oil from decayed seeds suggested the presence of lipase. The following data give the acid nos. of the oils extd. with Et_2O from 4 samples before and after 92 days at room temp., resp.: (1) seeds with husks, 5.41, 15.72; (2) crushed kernel with husk removed, 6.30, 48.82; (3) crushed kernel with oil removed and then ground with rapeseed oil, 1.20, 93.37; (4) same as (3) but
